In the study of the milder acute cases an interesting problem presented itself. By the milder cases is meant those cases in which there are distinct demonstrable changes in the mastoid but in which there is little or none of the gross destruction seen in the more severe cases. These cases may or may not progress to spontaneous recovery. The first change is that of fluid-filled cells. That is, the cell-spaces, instead of standing out sharply and clear, show by comparison with the opposite side that the air is displaced by a more solid substance, which may be serum, pus or granulations, or all three combined. The cell walls are fairly distinct and not broken down. This appearance of fluid-filled instead of air-filled cells is very characteristic of this stage; and in the attempt to draw operative indications from the plate the question as to how much bone change in the mastoid may occur without precluding spontaneous recovery, that is, what amount of skiagraphic bone change makes operation imperative, presented itself. Of course, I did not attempt to decide such a weighty problem. In discussion the fact that each text-book and each specialist has individual ideas regarding the pathology of acute mastoiditis was somewhat confusing. Those of the conservative school cite many instances of clinically severe mastoiditis which recover under the expectant treatment, whereas those of more radical tendencies advise early operative interference when fairly positive clinical evidence of mastoid involvement is at hand. The thought at once suggests itself whether it would not be possible by means of the x-ray to decide this point, and by a comparative x-ray study of a large series of cases to determine what amount of bone destruction makes operative interference imperative, if, indeed, the question can be settled at all. Although my series of cases is far too

small and too incompletely studied to warrant any definite conclusions, yet I adhere to the following tentative rule: If in an acute case the skiagram shows fluid-filled cells with little or no breaking down of cell walls, an expectant line of treatment is suggested, whereas, if the bone destruction is definite and considerable, operation is recommended.

The following two cases are typical of this milder type of mastoiditis:

CASE 7.—Mrs. E., aged 35, had for ten days suffered with pain in the ear. Examination revealed in addition to inflamed drum, pain and tenderness over the mastoid. There was some fever, 100° in evening 99.5° in morning. The drum was incised but symptoms continued a week unabated. An x-ray examination made at this time revealed the mastoid cells fluid-filled but little or no bone change. After two weeks, discharge gradually ceased and mastoid symptoms abated. Drum returned to normal, pain and fever disappeared, whispered voice heard at 12 feet. A second x-ray examination made two weeks later showed the affected mastoid apparently normal, the cells containing air.

CASE 8.—Mrs. M., aged 33, suffered severe pain in ear following an acute rhinitis. On examination, drum was bulging, covered with hemorrhagic blebs, mastoid tender over antrum. Drum was lanced and few drops of serum exuded followed by sero-bloody discharge which continued three days, and suddenly stopped. Pain returned. Drum was again incised, and mucoserous discharge continued. Marked tenderness was present over mastoid and antrum, extending toward tip, but there was no fever. After several days discharge again stopped, and buzzing and throbbing pain was complained of. X-ray examination at this stage revealed a haziness of the cells just back of the mastoid antrum, but not extending over the rest of the mastoid. The slight changes seen in the plate did not seem to warrant any active interference. From this time the case went on to recovery and a second plate made (two weeks after the first one) showed apparently a restoration to the normal.

Several cases similar to these were encountered at the Cincinnati General Hospital, but as the patients treated here often insist on leaving before entirely recovered and are then lost track of, the ultimate outcome could not always be followed. Of great interest would be some statistics as to how frequently such mild mastoid involvement goes on to ultimate recovery, and what percentage become chronic or give rise to intercranial or other complications.

ACUTE OTITIS MEDIA

After this success in detecting the milder changes in the mastoid a small series of patients with acute otitis media without clinical signs of mastoiditis was examined. To my surprise more than 50 per cent. of the patients skiagraphed gave evidence on the plate of slight mastoid involvement. This involvement was indicated by a slight haziness of the cells just back of or surrounding the antrum. The bone contours were, however, sharp and distinct.

The x-ray study of the mastoid region is submitted at this time as an aid in the obscure cases. A more extended study of a large series of cases will, it is hoped, put this work on such a firm basis that in any case an x-ray examination may yield results so valuable as to justify the procedure.

But the work has a broader application. By repeated examinations the course of a single case may be studied. By extended studies over long intervals of months or years some new phases of the pathology of mastoiditis may be brought out. The ultimate results of acute and chronic mastoiditis in early childhood, their influence on the development of the mastoid and the auditory func-

tion in later life, the final results of those types of mastoiditis in which the patients apparently recover without operation, and the relation of mastoid sclerosis to the capsule and functions of the internal ear, are problems on which systematic x-ray work may possibly throw some light. As a preliminary to such studies involving repeated exposures, it must first be determined at what intervals and how many exposures may be safely given without causing alopecia and what form of technic will best guard against it.

The cases of acute, subacute, and chronic otitis media in young children aged 1 to 10 presented such unique appearance on the skiagram as to warrant special consideration. It was my privilege to examine about ten patients of this kind, who presented no marked clinical signs of mastoid involvement. Almost without exception the mastoid showed changes varying from a slight haziness of cells in the earlier cases to more or less bone destruction in the more severe cases, while the chronic ones showed pronounced sclerosis. Owing to the small size of the cells and the immature development of the mastoid, the amount of bone change is often hard to determine in these cases. In every case, however, in which such haziness of the mastoid was evident if operation was subsequently performed, actual mastoid involvement was found, justifying operation. It would appear that in a majority of cases otitis media in early childhood is accompanied by distinct mastoid involvement. As mentioned above, the small size of the mastoid in these cases made it rather difficult to draw operative indications from the plate.

22 West Seventh Street.

ABSTRACT OF DISCUSSION

DR. HENRY HORN, San Francisco: Dr. Lange said that in about 50 per cent. of these cases of acute diseases there were some slight changes in the mastoid tip. That simply shows how accurate have been our clinical observations up to this time. There can be no question as to the value of the x-ray in the study of these conditions and in the study of accessory cavity disease, but the principal point is this: that it is essentially a matter for the expert x-ray man. It is out of the question for every physician, or even for every hospital to try it. An x-ray, especially of the accessory nasal cavities, must be sent to a man who has special expertness in this particular line of work. A man who makes a good pelvic or chest picture may not necessarily make a good plate in this work. Then, of course the enormous expense of the thing puts it exclusively in the hands of large clinics and makes it applicable here and there for the rich patient. As a clinical method of diagnosis it is valuable, but it is not yet one that can be used in general practice.

DR. CULLEN F. WELTY, San Francisco: This subject was up last year for discussion and I criticized it, as I am going to criticize it to-day for the following reasons: We have clearly defined indications for operative procedure in both acute and chronic mastoiditis; I would much rather depend on my judgment in an individual case, and possibly, I may say, do an unnecessary operation, than depend on any machine for making a diagnosis. I have operated in a few cases to my knowledge, in which probably the patients would have recovered without operation; at the same time I have not lost a single patient with acute mastoiditis and I maintain as an otologist that no such loss should occur. If we lean on this thing in one case and that thing in another we lose our individuality of judgment. We have all this work done for us and it makes us sleepy.

DR. F. E. AUTEN, Belleville, Ill.: I believe that the x-ray examination in mastoiditis is a valuable aid. It may be a little out of the reach of most of us but it should be used when available. I had recently a case in which the patient did

not want to have the mastoid opened and I would have liked very much to have this means of diagnosis at that time.

DR. SYDNEY LANGE, Cincinnati: The presentation of a method of this kind before an audience that has not had the opportunity of seeing and studying the plates and comparing them with the clinical and operative findings may leave a doubt in the minds of some as to its practical value. I purposely refrain from showing any lantern-slides owing to inadequate facilities for darkening the room, but I have many of the original plates with me which I shall be pleased to demonstrate to those who may be interested.

While in the average case of mastoiditis, the clinical features may be clear enough, I am convinced after speaking with a number of otologists that operative indications are not always clear, and I believe that all recognized authorities have so expressed themselves. Politzer in his book makes the statement that the most extensive necrosis may occur in the mastoid without any of the usual signs being present. And I have seen a few such cases of mastoiditis in which there were indefinite general, cerebral or septic symptoms without the usual local signs of mastoiditis.

In one case presenting obscure septic symptoms the greater trochanter of the femur seemed to be the focus of infection. It was drilled into and nothing was found. The cause was a broken-down mastoid which did not declare itself in the usual way. I have not examined any case of thrombosis of the lateral sinus but I do not think that the thrombus would show on the x-ray plate.

CONTINUED SUBNORMAL TEMPERATURE IN INFANCY*

HENRY W. CHENEY, M.D.

Associate in Pediatrics, Northwestern University Medical School
CHICAGO

The opportunity to observe and study a case of continued subnormal temperature in an infant, recently, has interested me in the subject.

On looking up the literature, however, one finds much written about fever and increase of temperature, but very little recorded or written on subnormal temperature. The text-books, also, usually dismiss the subject with a few lines or, perhaps, in the description of a disease, merely say that the temperature may be below normal.

Have we not, as physicians, been too prone to disregard those depressions of temperature below normal and to consider only the occurrence of fever as of clinical significance? We do this perhaps from indifference or because there seems no ready explanation of the hypothermia.

Cases of noticeably low temperature in adults appear to be recorded more often than do those of infants or children. Then too, the cases observed have been usually of some fatal illness and the hypothermia was marked just prior to death.

Munson¹ of the Craig Epileptic Colony reports eighteen cases of subnormal temperature, more or less continuous, in which three patients were children. All were epileptic and all died. Of the children, one was a girl of 7 who was both tuberculous and epileptic and had a temperature of 91 F. before death. In the other two children the temperature sank as low as 81 in one case and to 76 in the other, both of course fatal. J. H. Williams² reports a 5-months-old babe with tuberculous

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Munson: Some cases of Low Temperature, Arch. Int. Med. 1910, v. 120.

2. Williams, J. H.: Med. Rec., New York, 1898, p. 640.

meningitis in which for ten days preceding death the temperature was below normal, hovering around 94 and 96 and at one time going as low as 87. Dr. F. W. Loughran³ reports a 6-weeks-old babe who died of septic infection. The last two days before death the temperature varied around 84 F. and even dropped as low as 80 F. These references were all that could be found of definitely recorded cases in children or infants.

Other observers agree, however, that the condition of low temperature is usually a serious one, and much more liable to be disastrous than a corresponding elevation above normal. Inquiry among my friends who also see many babies elicited the fact that temperature below normal is not so uncommon, but that the condition seldom lasts long and is almost always followed shortly by death. In other words the usual subnormal temperature is a terminal condition.

Suppose we now inquire what are the sources of heat, and how an even temperature is maintained in the human body. It is probably unnecessary to mention that physiologists agree that the origin of the body heat is the oxidation of the food materials taken in. Just where this oxidation takes place is not well understood. There is little doubt that the energy manifested by the activity and work of the muscles, both voluntary and involuntary, is an important factor in heat production. This heat is distributed by the fluids of the body to its various parts and members. Heat production, then, in the muscles is controlled by the nervous system and, correspondingly, heat loss is regulated by the vasomotor and by the respiratory nerves. All of these various acts of heat production and heat loss are undoubtedly under the control of the heat center in the brain, which constantly exercises its governing influence. Thus we have the condition of a steady, even body temperature most highly developed in man, who, of all the animals and in spite of environment, maintains in health a constant temperature which varies but a minute fraction day after day and year after year.

In infants, however, this fine regulation is far from perfect and is easily disturbed. Thus we find slight causes creating greater disturbances in the child than in the adult.

Let us consider what are the causes of continued depression of temperature. These may conveniently be grouped under four heads:

1. Insufficient heat production.
2. Excessive heat loss.
3. Disturbed heat regulation.
4. Diseases of metabolism.

Under the first heading, insufficient heat production, may be classed those cases due to starvation or stenosis, to infantile atrophy or athrepsia, to the condition of prematurity, to inanition and to inactivity. Under the second, excessive heat loss, we place those cases caused by loss of body fluids, as in severe diarrheas or hemorrhages, also perhaps certain skin diseases. Under the third head, disturbed heat regulation, are the cases occurring in disease of the heart and nervous system, those due to drugs, to unconsciousness and to intoxication. The fourth head includes certain diseases of metabolism such as anemia, diabetes, and myxedema.

The first group of causes, namely, starvation, atrophy, prematurity and inanition are perhaps more likely to affect young infants and are often the cause of subnormal temperature.

One can easily understand also, how the loss of a considerable amount of fluid from the body, as in diar-

rhea or hemorrhage would, at the same time, lower the body temperature. The diseases of the skin in which the temperature is lowered are sclerema neonatorum, large or excessive burns and perhaps, also, severe cases of pemphigus.

Among the drugs which cause a temperature below normal are the general anesthetics, such as ether and chloroform, also nicotin and morphin. Alcohol, contrary to former views, does not raise temperature but depresses it, as I shall show later. It acts thus because it increases heat loss by superficial vascular dilatation and diminishes heat production by limiting muscular activity. Possibly, also, the heat center is directly affected by alcohol.

There seems to be some relationship between consciousness in an individual and a steady temperature. For do we not often find a subnormal temperature after the use of general anesthetics and of hypnotics, and also in profound sleep or concussion of the brain, in severe collapse or in the last stages of a fatal disease? In myxedema it is not at all uncommon to find a subnormal temperature and this has also been observed in diabetes and severe anemia.

It is perhaps needless to emphasize the fact that great care must be used in taking the temperature in infants and also in recording it, so as to make the record accurate and valuable. In infants the rectal temperature is undoubtedly the most reliable and this was the method employed in the case here reported. The various temperature readings in this case were all taken and recorded by trained nurses accustomed to the work and when the figures seemed especially low, another trial was made with a different thermometer, so that I am quite sure the temperatures, here recorded, may be depended on.

REPORT OF CASE

The history of the case I desire to report was as follows:

The babe was a 3-months-old girl when she first came under observation. The father had poor health, was an alcoholic and died of delirium tremens two months before the babe was born. The mother was in good health and this was her first and only child. She worked up to within four days of the birth. Labor was not difficult, lasting only three hours.

The babe was never strong and was breast-fed only three weeks. Then began artificial feeding, first malted milk, later condensed milk. She did not take the food well and had to be fed with a spoon. The baby's birth weight was not known but at 1 month of age she weighed 5¼ pounds. She began to get thin when 6 weeks old and continued getting thinner until her admission to the hospital, when her weight was 4¼ pounds.

There was some gastro-intestinal indigestion on her entrance to the hospital, shown by occasional vomiting, undigested stools, etc. This, however, soon cleared up under a proper diet and daily colonic flushings.

The infant remained at the hospital for nearly five months, during which time the temperature was more or less continuously subnormal, on one day going as low as 89 F. and frequently reaching 92 and 93 F. It was the exception for the temperature to reach 98 or 99 F., and only a few times did it go above those figures. For one whole week it was below 96, varying for the most of that time from 92 to 94.

The babe was fed a mixture of fresh cow's milk and water, the caloric value regulated somewhat as to the child's weight. She was either too weak or had no desire to suck her food through the nipple, for most of the time she was fed by a spoon or through a stomach-tube. The stools showed usually that digestion was good. The weight increased very gradually from 4¼ pounds on admission to 5½ pounds when discharged.

The child may have been syphilitic but an inunction of mercurial ointment daily for two weeks made no permanent effect on the temperature curve.

3. Loughran, F. W.: *Pediatrics*, January, 1908.

As illustrating the harmful effects of alcohol in such cases, it may be of interest to mention that small amounts of whisky varying from twenty minims to two drams were given on six successive days when the temperature began to be low, with the expectation of raising it thereby. But, on the contrary, it fell to 92 and on the two days following remained continuously below 93. Later the whisky was tried again and from the sixty-fourth to the seventy-first day about one dram was given daily, when the temperature declined rapidly and, on the third day following, reached 89 F., the lowest observed.

External heat in the shape of hot-water bags was applied continuously for two weeks at first, without appreciable effect. A hot-water bath at a temperature of 105 F. was also tried daily for ten days, but with no permanent change noticed.

When the child was 7½ months old it left the hospital and has been lost track of; but it was apparently doing as well as usual, when it left, and was gaining slowly in weight, although the temperature was still the subnormal type.

The interesting question is, what the cause was of the continued low temperature in this case? I think it would come under the first heading in our classification, that of incomplete heat production. No doubt the condition of inanition had much to do with it. The inactivity also was a cause. The child was not active and playful as other healthy babes are, but would lie quietly in one position much of the time, making almost no disturbance and crying little. Although several months old it resembled the premature infant, because it had to be fed by hand; it was quiet and passive and lacked the life and vigor of a normal child.

The question has been raised whether or not there is anything in this condition analogous to the state of hibernation in animals. I find on looking it up that the hibernating state also is not fully explained or understood. Pembrey⁴ says that during hibernation the temperature of so-called warm-blooded animals is much depressed resembling that of the cold-blooded animals; also that respiration and heart action almost stop and that absolutely no food is taken. There is an intermediate stage, however, when the animal is listless and inactive and with a body temperature below normal. In this condition its power of heat regulation resembles an immature mammal.

We cannot carry the analogy far, however, for the subnormal temperature and the inactivity are the only points of resemblance and, unlike the hibernating animal, this child's respiration and heart-beat were active and food was taken regularly.

My reasons for presenting this subject are, partly, the desire to place on record an unusual case and, partly, the hope that the discussion may bring out something further as to the causation and treatment of cases of subnormal temperature.

1230 East Sixty-third Street.

ABSTRACT OF DISCUSSION

DR. J. S. LEOPOLD, New York: I should like to ask Dr. Cheney how much the patient gained in weight during the period of observation? I have seen several of these cases of subnormal temperature in infants and the picture in this case seems to me to resemble very closely what is known in America as atrophy, and what Finkelstein calls "decomposition." There is loss of weight, subnormal temperature and at times collapse. The temperature usually becomes normal as soon as the weight curve remains stationary. Often subcutaneous injections of saline solution do good in these cases and bring the temperature up to normal.

DR. GODFREY R. PISEK, New York: I saw in consultation one of the cases the author cited. The case was one of infantile

atrophy. The temperature was 84 F. I remember I had to get a dairy thermometer to take the temperature. In that case all manner of expedients were tried to increase the temperature, but they failed. Hot-water packs, hot colonic flushing all failed, and in forty-eight hours the child died. In this case the condition of subnormal temperature had probably existed and been unnoticed for several weeks. These cases can be accounted for by profound disturbances of metabolism.

DR. WILLIAM J. BUTLER, Chicago: I believe the doctor mentioned one case of tuberculous meningitis running a subnormal temperature. I think it is rather the exception to see a subnormal temperature in these cases, although it is often but little above normal. I recall seeing a case of what was apparently meningitis running a subnormal temperature. In that case the temperature was subnormal all of the time; about 96 F. was as low as it went. There was dulness in the right apex. I thought it was either hemorrhage into the posterior fossa or a tuberculous meningitis with subnormal temperature. The middle ground was taken that it was possibly a combination of both, and the post-mortem showed tuberculous meningitis and hemorrhage into the cerebellum. In this case there was arteriosclerosis, with its associate heart changes, and struma of one suprarenal.

DR. FRANK GENGEBACH, Denver: What was the condition of the pulse, the result of examination of the heart and the appearance of the skin as regards cyanosis?

DR. H. W. CHENEY, Chicago: There was no loss of weight; the child made a gradual gain, weighing 5½ pounds when it left the hospital. As to the administration of some of the sodium salts, I think in another case I will try it, as they are said to cause a rise of temperature in infants. As to the heart action and condition of the skin, the pulse itself was about what would be normal for a child of that age. The skin was somewhat anemic, such as we can expect to find in an atrophic child like that, but there was no cyanosis. As to other measures, Dr. Coit says that he keeps these babies in a separate room with a temperature at 75 or 80 F. This baby was kept in a room with other children. Possibly an incubator might be tried with satisfaction.

IN MEMORIAM: WILHELM MEYER*

HOLGER MYGIND, M.D.

Professor of Laryngology in the University of Copenhagen
COPENHAGEN, DENMARK

My first words to-day must be words of thanks to the chairman of the Section on Laryngology and Otology of the American Medical Association, Dr. Chevalier Jackson, and to the other members of the committee for the honor they have shown me by inviting me to this session and asking me to read a paper here.

Permit me to say that it is a great and heartfelt pleasure for me to be among you and to meet so many confrères, whose names have for years been familiar to me; above all I appreciate the opportunity of seeing again the faces of old and faithful friends, though, alas! I miss some, who, having completed their appointed task, are now at rest.

It is, however, not without considerable hesitation that I have accepted your kind and gratifying invitation, for I have but little news to tell you with regard to our specialty—a specialty in which America occupies so prominent a position—but I feel that the attention paid by you was not only to myself but to the Danish school of laryngology founded by my late dear and honored master, Wilhelm Meyer. Such being the case, it may not seem inappropriate if, before speaking on more special and scientific topics, I give you a brief sketch of the life

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

of that great otologist, to whom we are all so deeply indebted. Would the manner were worthy of the matter.

Wilhelm Meyer was born in 1824 in the Danish town of Fredericia, where his father was a regimental surgeon in the Danish army.

In 1826 the family removed to Glückstadt in Holstein. Here Meyer passed his childhood and youth until, in 1843, he entered the University of Copenhagen as a student. Meyer's mother came of an old Danish family and she remained faithful to her native land until her death; his father, who was born in Eckerförde in Holstein, and the remainder of the family were distinctly German in their sympathies. Accordingly, on his return to Glückstadt after completing his studies in Copenhagen, Meyer found the greater part of his family circle hostile to Denmark.

For some time he assisted his father in his private practice in Glückstadt and while thus engaged caught scarlet fever. It was during the period of his convalescence after this illness that the insurrection against Denmark broke out in Schleswig-Holstein (1848). Meyer's father, to whom he was tenderly attached, immediately left the Danish army and joined the Germans, and it was doubtless owing to his persuasion that his son was induced to enter the insurgent army as a surgeon, the attack of scarlet fever having prevented his return to Denmark at the outbreak of war. Later he was, however, a Dane with his whole heart, and, as I have often heard him assert with warmth, loved his native country truly.

As a student at the University of Copenhagen, where he took the highest honors attainable, Meyer had greatly distinguished himself, and on his return to Copenhagen after the war of 1848-50 he was offered a position as physician at the University Hospital by Professor Fenger. But so bitter was the feeling against him at that time that the students called a general meeting to protest against any public office being filled by one who had served in the insurgent army. Meyer was thus shut out forever from that brilliant university career which his talents would undoubtedly have procured him.

After this he travelled for some time, visiting various European universities, studying principally internal medicine and forming friendships with many foreign colleagues which were to prove of lifelong duration. In 1853 Meyer established himself as a general practitioner in Copenhagen. At first he had a hard struggle, but it was, as at all times during his career, in unremitting labor that he found both his compensation and refuge. During this period he produced his first scientific work on "Bread, Especially Rye Bread," an extensive essay, principally remarkable for its thoroughness—one of Meyer's most characteristic qualities. By degrees his circumstances improved, clients became more numerous, and in course of time he became one of the most sought-after of private practitioners in the whole of Copenhagen.

It is, however, as an otologist that Meyer will be remembered, and, as he has often told me, it was his pity for suffering humanity that first attracted him to this specialty. In his extensive practice he constantly came across patients whom deafness, buzzing and pains in the ear had rendered almost desperate. Such patients the majority of the medical men of that period were only too glad to get rid of as quickly as possible, considering the ear to be a *noli me tangere*, and for which no treatment was possible beyond the ordinary syringing with water or dropping in of warm milk and oil. In the hope

of rendering some assistance to such unfortunates Meyer made an exhaustive study of the otologic literature then existing, and, purely self-taught, he became by degrees one of the greatest otologists of his time.

It was while engaged in the treatment of ear diseases that Meyer made the discovery of the adenoid growths, a discovery which for all time will be associated with his name. On Oct. 22, 1867, a young girl came to his surgery to be treated for deafness. Meyer observed that in this case nasal respiration was almost totally impossible, even after treatment for chronic catarrh of the nose and of the throat, which did not alleviate the deafness. He came to the conclusion that respiration was impeded by causes to be sought for in the nasopharynx, and he therefore explored this cavity by passing his finger up behind the soft palate—which, strange to say, no one had done previously—and he found the nasopharynx full of peculiar swollen growths, on the removal of which respiration became perfectly free and the hearing improved.

Meyer now began to suspect that these growths were the cause of the patient's deafness, and on examining other patients with ear trouble found in several the same conditions in the nasopharynx. He continued his researches with characteristic patience and energy, and in 1868 published his first article on the subject in the Danish medical paper *Hospitals-Tidende*. In 1869 Schmidt's *Jahrbücher* had a report on this article, and in 1870 Meyer published his further investigations in *Medicochirurgical Transactions*, without, however, attracting much attention to the subject.

In 1873 Meyer published his classical description of "Adenoid Growths, Their Etiology, Pathologic Anatomy, Symptomatology, Consequences and Treatment" in the *Archiv für Ohrenheilkunde*, earning now for his discovery universal recognition and for himself undying fame.

Besides shorter articles relating to his specialty Meyer wrote an excellent paper in the *Archiv für Ohrenheilkunde* demonstrating the importance of necrosis of the walls of the tympanic cavity as an etiologic factor in chronic suppuration of the middle ear.

Great as he was as a physician, Meyer as a man was even more worthy of admiration, uniting, as he did, the highest qualities of head and heart. A remarkable memory, strong power of observation and a keen critical faculty bore witness to his superior intellectual powers. The last he employed impartially and so ruthlessly was he wont to criticize his own literary productions that authorship cost him an immense expenditure of time and labor. He therefore wrote seldom and unwillingly. I may mention in this instance that he was eighteen months writing his paper on the history of otology in Schwartz's large "Handbuch der Ohrenheilkunde," although it is only forty-eight pages in length. He first wrote a long and comprehensive essay, which he condensed and abbreviated twice before reducing it to the length desired for the "Handbuch." This little work is, however, justly esteemed a standard work, both on account of the learning it evinces and of the purity and polish of the style.

To these great intellectual powers Meyer added an almost unique industry and power of application. He was absolutely never idle. After a long and arduous day's work he would sit up far into the night reading not only medical works, but also works on all subjects which could interest the cultured mind: natural science, philosophy, literature, religion, etc. His knowledge was marvelous. He was an enthusiastic lover of music and

no mean performer on the piano. As an astronomer he was more than an amateur, and many a summer and winter night has he spent studying the heavens through his large telescope. Finally, I may mention those wonderful linguistic gifts, which, as some of you may remember, aroused such universal admiration among his colleagues at the International Medical Congress in Copenhagen in 1884.

But noblest of all was that warm and faithful heart, which, beating under a seemingly formal and cold exterior, endeared him to all who had the good fortune to become intimate with him. To his patients he was always the tender and self-sacrificing physician for whom no labor was too wearisome. He was a faithful friend whose value was especially felt in adverse fortunes, and, though severe toward himself, he was always exceptionally lenient in his judgment of others.

Meyer married, at the age of 46, Catherine Jane Emerson, a widow, by birth Baroness de Bretton, a relation of Sir Lytton Bulwer. By her he had three children, all of whom are living. His son is a medical man in Copenhagen.

It was during a journey in Italy, in 1885, undertaken after a severe attack of influenza, that Meyer, who was then 71 years old, contracted the typhoid fever which in the brief space of a week brought the seemingly healthy man to his grave. His body is interred in the beautiful island cemetery at Venice, a fitting resting-place for one who ever loved the sea and had made his much-loved summer home on the very verge of the beautiful Danish Sound, so that the music of the waves might be ever in his ears. Of all who loved him—and they were many—none but his wife, who died a few years later, and one daughter had the privilege of following him on that last solemn journey over the silent waters of the lagoons. A simple stone marks his last resting-place.

The medical profession, however, felt that to the memory of so distinguished a member honor was due, and at the initiative of Sir Felix Semon a monument was erected in Copenhagen by subscription from all parts of the world as a graceful tribute to one of whom I can truly say:

He was a man, take him for all in all,
I shall not look upon his like again.

OBSERVATIONS ON THE VOCAL CORDS IN ONE THOUSAND CASES OF GOITER *

JUSTUS MATTHEWS, M.D.
ROCHESTER, MINN.

My report is made on the observations of the vocal cords in 1,000 cases of goiter examined during the past two years. About 95 per cent. of the patients were operated on; all were examined before operation and re-examined after operation.

The anatomy of the larynx may be passed over with the exception of the motor nerve supply of its intrinsic muscles, which will be considered only with reference to liability to paralysis from pressure by enlargement of the thyroid gland.

The cricothyroid muscles, which are the tensors of the vocal cords, are supplied by the external branches of the superior laryngeal nerves from the pneumogastrics. These branches enter the muscles so high that only the largest lobes, which extend unusually high on the throat,

can exert pressure on them. All the other muscles, including abductors, adductors and decreasers of tension, are supplied by the recurrent laryngeal nerves, which also arise from the pneumogastrics. These opposing muscles are supplied by different fibers which merely travel in the same nerve trunk, either set of which, or all together, in any degree may be subject to paralysis.

In this series of cases, as well as in the observations of others, it appears that the fibers supplying the abductor impulse to the posterior crico-arytenoid muscle are the most readily affected by pressure.

The right inferior laryngeal nerve arises at the level of the right subclavian artery and, winding around that vessel, passes upward in the groove at the right side of the trachea and esophagus and enters the larynx at the edge of the cricoid. The left inferior arises at the level of the arch of the aorta around which it passes and ascends on the left in the same manner as the right inferior nerve. The relation of the left laryngeal nerve to the aorta and its longer course account in part for the fact that it is more frequently affected by local pressure. Moreover, the position of the esophagus to the left of the median line forces the nerve to take a position more exposed to pressure, especially at the level of the thyroid gland.

EXAMINATION OF CASES

In the examination of 1,000 cases there were found seventeen with paretic affections of both cords, ninety-three of the right cord and 162 of the left, making a total of 289 partial or complete paralyses in 272 individuals. Total paralysis of the right cord occurred eighteen times; of the left, thirty times. Partial or complete abductor paralysis of the right occurred fifty times; of the left, eighty-three times. Partial loss of both motions of the right occurred thirty-eight times; of the left, sixty-two times. Bilateral tensor paralysis occurred in four cases.

In classifying the cases as to the size of the right, median and left lobes, a division was made for each one-half inch in diameter. It was found that paretic conditions of the right cord increased from 5.3 per cent. in 226 cases with small or non-palpable right lobes to 25 per cent. in eight cases with lobes over 5 inches in diameter. Abductor paralysis and partial paralysis of both movements increased more rapidly in goiters ranging up to 3½ inches in diameter, and then gave place to a relatively greater increase of total paralysis. The left cord showed 10 per cent. of paresis in the goiters with small left lobes, increasing to 47 per cent. with those over 5 inches in diameter. There was a still more marked tendency for all affected cords to become totally paralyzed as the lobes became larger. This occurred in five of fifteen cases. Even great enlargement of the median lobe alone was seldom associated with affections of the cords. Total paralysis occurred in but two such cases; bilateral tensor paralysis in four, and minor affections in nine. In nearly every division, except that of the largest lobes, abductor paralysis, either partial or complete, was the lesion most frequently seen.

Although the average frequency of symptoms of pressure on the nerves was directly proportional to the size of the lobes, there were exceptions. For example: paralysis occurred when the corresponding lobe was not palpable. On the contrary, in some cases which had the most tremendous enlargement of the lobes, displacing and distorting the larynx and the trachea, there was no apparent effect on the movements of the cords.

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910

In a series of 100 consecutive cases in other than goiter patients, or patients coming on account of laryngeal symptoms, there were found one case of total paralysis of the left cord without noticeable symptoms, one case of partial and one of complete abductor paralysis, and two of partial loss of both motions of the left cord. In one case only, the right cord showed a deficiency of both motions. These patients were more than normally liable to affections of the cords, since most of them came for other pathologic conditions in the nose and throat. But, since goiter patients are also especially affected by diseases of the nose and throat, it might be considered proper to deduct from the percentage due to goiter the 6 per cent. found in these cases. This would, in cases of slight enlargement of the thyroid, make the percentage for the right and left cord nearly equal, while in cases of greater enlargement the left cord would still show a relatively greater tendency to paralysis from pressure, probably on account of the more exposed position of the left recurrent laryngeal nerve.

The position of the lobes is quite as important as the size of the goiter, since, for goiters of the same size,

RESULTS OF OPERATION

In five cases the partial paralysis observed before operation had disappeared after operation, showing that the pressure must have been of short duration and not sufficient to cause permanent degeneration of the nerve. In eight cases of partial paralysis following operation, probably due to the pressure of edematous tissue in the region operated on, later observations showed complete recovery. Twenty-two case of partial paralysis following operation were observed but once, so that the ultimate result was not ascertained. In several cases with disturbance of phonation after operation, positive diagnosis could not be made between paralysis and edema.

Twelve cases of total paralysis followed extirpation of the lobes; three of these were malignant. Two cases followed ligation of the thyroid artery. In four of these cases aphonia appeared two or three days after operation, indicating that the cause was pressure and not section of the nerves, and therefore that the prognosis was good. No patient with total paralysis, observed either before or after operation, was seen to have recovered, though, through lack of opportunity for reexamination

affections of the cords are much more frequent in those cases with lobes located near the clavicle, especially if all or a portion of the goiter is intrathoracic. Exceptions to this are the cases in which the large lobes extend so high as to reach the external branch of the superior laryngeal nerve. This condition occurred in four cases which showed bilateral tensor paralysis caused by large, high median lobes. Firmness is likewise important, since small, hard lobes are more apt to injure the nerves than larger soft lobes.

Long duration of the goiter increases liability to vocal paralysis, probably because as a rule the older cases have the greater enlargement. Apparently there is also an additional danger from long-continued pressure.

Men are about three times as liable as women to paralysis from goiters of the same type.

Exophthalmic goiter does not differ materially from other forms of goiter in its effects on the vocal cords, except in cases of extreme hyperthyroidism, in which its effects are evidently increased as a direct result of general wasting of muscular tissue.

The age of the patient has no demonstrable relation to the pressure on the recurrent laryngeal nerves except that goiters of large size and long duration are more frequently found in older individuals.

after the lapse of considerable time, such recovery might have escaped notice.

The frequency of parietic conditions, often without change of voice or other symptoms, emphasizes the necessity for careful laryngoscopic examination of all cases before operation. This is important, since it is essential to the prognosis of postoperative lesions and might be especially valuable in some cases, as showing the possibility of repairing damage by suturing the nerve severed during operation. Moreover, a beginning paralysis of the laryngeal muscles, apparently due to the pressure of the goiter, would be an indication for early operation in order to prevent complete and permanent degeneration of the nerve.

ABSTRACT OF DISCUSSION

DR. W. B. CASSELBERRY, Chicago: Elsewhere I have advocated the examination of the larynx in every case of goiter and have stated that paralysis, leading toward impairment of the voice, might be the determining factor in advising an operation for removing the bulk of the thyroid. There are so many cases in which there is hesitancy, where it is doubtful whether the patient should take the risk of operation, the symptoms not being extremely urgent, that if the vocal cords are examined and impairment of one or both observed it would plainly justify operation. I have had a case operated under these circumstances. Nowhere in the

literature have we reports of such numbers of accurately observed cases. The essayist referred to one point that I would ask him to be a little more explicit, that is, whether he noticed preliminary paralysis of those nerves which cause the vocal cords to separate, thus permitting the closure of the glottis with dyspnea, to precede for a time the total paralysis of motor innervation. This greater vulnerability of the abductor fibers of the recurrent laryngeal nerve is known as Semon's law. I have noticed it in cases of compression of the nerve by aneurysm of the aorta. Even though the paralysis be one-sided, if that cord is fixed in the closed position, and there is a little swelling of the other side as from the "cold," dyspnea is produced. I would also ask whether he has observed from pressure by goiter a paroxysmal barking cough, which I have observed from pressure on the laryngeal nerves by enlarged lymphatic glands, especially by one gland located on the right side almost under the clavicle.

DR. GEORGE F. COTT, Buffalo: I should like to call attention to the fact that in the removal of the thyroid, either partial or total, it is almost impossible to tell whether you are going to have paralysis on one side or not. It is sometimes impossible to find the thread-like nerve, especially if you have a good deal of bleeding; you are liable to include the recurrent laryngeal or to injure it. You may get paralysis days or weeks afterward, which, however, usually recovers. It does not always depend on the expertness of the operator either. The best men get a certain percentage of paralyses. I know a number of men who are most expert who have had this happen. I have had in twenty cases one case of paralysis that I know of and I think the reason I haven't observed more is that I did not examine the larynx in the others.

DR. HENRY HORN, San Francisco: The essayist did not speak of a preliminary bronchoscopic examination of these patients, so I suppose it was not carried out. It would have been of extreme interest and I think it is going to be one of our preliminary methods of examination in all cases of struma. I hardly feel competent to speak of the surgical treatment of struma, but in certain cases of large cystic goiter where there is dyspnea it is often a question to know how much to remove. If the bronchoscopic examination shows a half circle formation we know from the start that the operation can be made on that side and afterwards the cystic tumor on the other side will come to the middle and there will not be so much deformity. It is a bad term to use "bronchoscopic examination" for these cases as it is not necessarily that, but a tracheoscopic examination. It is an exceedingly simple procedure to pass the small tube of the tracheoscope in far enough to examine the sub-glottic region, and it seems to me that it is a means of diagnosis that should not be overlooked. There are three cases, so far as I know, of what is called tracheal struma and the second was diagnosed by means of the bronchoscope. For these reasons I hope that a great many will acquire enough experience to make such a diagnostic examination, which I consider entirely justifiable. In fact, I believe a great many general physicians will find these examinations much easier than the use of the laryngoscopic mirror, for there are still many general practitioners who cannot use the mirror satisfactorily.

DR. GEORGE PAUL MARQUIS, Chicago: Carrying out the idea the last speaker has given us, I think a great many diagnoses as to whether these cases of struma are operable, and as to the extent of operation advisable, can and should be made by means of the bronchoscope. I have during the past winter made several examinations for some of the Chicago surgeons for this purpose. In one case a diagnosis was made by the bronchoscope in which there was no enlargement of the gland on the outside, and by direct laryngoscopy I could not see any involvement, but on using the tracheoscope I found the condition about two inches below the vocal cord. The operation was performed by the surgeon and it was found that there was a lobe pressing from the posterior surface of the trachea. This diagnosis could not have been made in any other way.

DR. JUSTUS MATHEWS, Rochester, Minn.: As to Dr. Casselberry's question with regard to the comparative frequency-

of abductor paralysis, it occurred in 133 cases of my series while partial paralysis of both cords occurred in only 119. But while abductor paralysis was much the more common, I found in only a few cases abductor spasm associated with it. I attribute this to the gradual increase of pressure due to slow growth of the goiter which did not produce sufficient irritation of the abductor fibers to cause spasm. I found it in about eight or ten cases. Cough, associated with abductor paralysis, was not a rare condition, though not common. I found it, I believe, in at least fifteen cases. It was necessary to make a differential diagnosis between cough due to nervous irritation and cough due to colds or bronchitis, with relation to the giving of an anesthetic. The indication being to operate immediately in case of the former and to delay operation in case of the latter. We rarely, if ever, used the bronchoscope or tracheoscope in the examination of goiter patients, since most of them were to be operated on and the exact condition could be more accurately diagnosed at operation, and the passing of instruments would result in more or less inflammatory reaction that might delay operation. Our patients are practically all non-residents and anxious to be operated on and go home, so we make no unnecessary manipulations that might delay operation.

THE CURRENTS AT THE EASTERLY END OF LAKE ERIE AND HEAD OF NIAGARA RIVER*

THEIR INFLUENCE ON THE SANITATION OF THE CITY OF
BUFFALO, N. Y.

GEORGE EDWARD FELL, M.D., F.R.M.S.
BUFFALO

Buffalo for many years has taken its water-supply from an intake near the center of the Niagara River, near its head at Lake Erie. The current at this intake runs from 7 to 9 miles per hour, carrying "220,000 cubic feet per second," which was considered at the time of the location of the intake as a valuable factor, influencing the character of the water through its rapidity. A location much nearer to the American shore or Bird

Fig. 1.—Chart of Lake Erie, trend of current easterly. The body of one of the victims of the wreck of the car ferry, shown in the illustration, was found in the Niagara River three or four months after the disaster. It had floated eastward with the current.

Island pier was recommended by one of the engineers, but fortunately for the future of the sanitation of the rapidly growing city this was not adopted. The general course of the currents at the head of the river and in the lake had virtually nothing to do with the question of location. To the southward the sewage of the city was thrown partially into Buffalo River, which in its

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

current course down the Niagara runs with its contaminated water close to the American shore and gave most positive proof of its virulent nature (Figs. 1, 2, 3, 13 and others).

From the following account of the typhoid fever epidemic (Buffalo, 1894) it is seen how quickly an epidemic can be produced by contaminating the water supply of a great city. In the month of January, 1894 (official reports), there were twelve cases of typhoid fever in the city; in February eleven cases. Fine ice coming down the river clogged the entrance to the intake in the middle of the river. In the emergency, and as a provision in case of a large fire, the Bird Island inlet (No. 13) at the easterly side or shore of the Niagara River was opened and more or less of the waters of the contaminated Buffalo River pumped into the water-supply in March, 1894. The number of typhoid fever cases

westward of the long series of United States breakwaters, which the charts indicate (Figs. 3 and 4 with and without the breakwaters).

CONDITION WHICH BROUGHT ABOUT THIS INVESTIGATION

On the charts (Figs. 2, 3, 4 and 5) will be noted the location of Smoke's Creek, and the Lackawanna Steel Plant, which was under construction when, in the fall and winter of 1903, an epidemic of typhoid fever broke out along the banks of the creek where the laborers were living under deplorable conditions.

Happening at the same time as the noted epidemic at Ithaca, N. Y., the conditions were considered somewhat parallel by many prominent physicians. One prominent physician said, (so reported), "What they have experienced at Ithaca we are liable to experience at any time from the same condition." A representative of the state board of health reported, "Existing conditions were excessively dangerous to residents of the immediate neighborhood, and to the people of Buffalo."

Fig. 2.—Eastern end of Lake Erie, City of Buffalo and head of Niagara River.

jumped from 11 cases in February to 510 cases in March. As soon as the cause of the epidemic was discovered and the shore intake closed, the cases decreased in number, so that in June, 1894, but 15 cases were reported by the health authorities. Just remember this when we discuss the possibility of throwing an entire winter collection of typhoid epidemic debris into the same water-supply.

Now to indicate that the water of Lake Erie to the southward of Buffalo and about a mile out in the lake is clinically, and virtually bacteriologically, pure, we note that the intake of the western New York water works, from which the supply to the community of Father Baker, numbering several thousand, has been supplied for years, has never known a case of typhoid fever. This is the character of the water according to the testimony of the currents which dominate the area directly

Fig. 3.—Shore outline chart, from Smoke's Creek, the epidemic district to Buffalo Water Works intake.

The health commissioner of the city, and 90 per cent. of the physicians of the city through newspaper interviews voiced but one opinion, and that was of positive and certain great danger when the spring freshets carried the debris from the typhoid district at Smoke's Creek out into the lake. The epidemic of 1894, costing over a hundred deaths, was not forgotten. But the general belief was openly expressed in one of the most prominent newspapers of the city of March 1, 1903. The article was headed, "Buffalo's Peril and Its Source." A chart of the lake front on the front page of the paper, depicting the outflow from Smoke's Creek, coursing outside of the breakwaters (Chart 4 with breakwaters), and directly toward the intake, had the following description of the impending disaster:

The above map, showing the source of the city's water supply conveys a striking object-lesson to the people of Buffalo. Near the top is shown the pumping station, where water is drawn from Niagara River to supply the city.

At the lower end is seen Smoke's Creek, emptying into the lake its daily burden of pollution in the form of millions of disease-breeding germs, the drainage of the great steel plant colony at that point. The currents all set directly toward the point where the lake empties into the Niagara, and the outlying breakwalls direct this deadly filth-laden current toward the intake of the Buffalo Water Works. (Chart 4.) All winter long an army of laborers have been working at this point and living in improvised shacks on the premises. There is no sewerage, and slops and filth of every description have been dumped in immense quantities on the surface. With the first spring thaw this entire mass of pollution must inevi-

Fig. 4.—Shore outline chart, with breakwaters constructed by the U. S. Government, showing erroneously supposed course of currents from Smoke's Creek.

tably be washed into the lake, and no human power can prevent its being swept out into the Niagara River, pumped into the reservoir, and distributed with its burden of disease and death throughout the length and breadth of the city.

These reports naturally spread consternation in the city, gave the city a bad name abroad, kept industries away (so reported), and did great harm to the community.

When this agitation was its height, I questioned the truth of it, and stated to the editor of a leading paper that there was no reason for such a scare, that it was uncalled for, and that proper investigation of the currents of the lake and river would so demonstrate. My stand was actually ridiculed by one paper. I was berated for presuming to question the statements of the authorities as though an old citizen had no right to assist in protecting the community in which he lived, under such contingencies. It being a public matter, I gave to the public the following statement:

When a careful study is made of the currents at the head of the Niagara River it will reveal that we are not in any danger of having our present intake supply of water seriously infected with septic material coming either from Smoke's Creek or Buffalo River, not only in the spring freshets, but any time under existing conditions.

I was opposed *in toto* to the views of the great majority of our leading physicians and the state and city health authorities. But one physician, as I recall it,

Dr. Matthew D. Mann, of the hundreds interviewed, expressed the idea that the currents might avert the threatened disaster.

Through the assistance of the editor of a prominent paper I obtained the use of the little steam yacht *Empire* and its old engineer, and demonstrated to my satisfaction by preliminary experiments, the truth of my assertions. This was as far as I intended to proceed, as I had not time to give to a more complete investigation of the subject. The mayor of the city, Hon. Erastus C. Knight, knowing of my former experience as a hydrographic engineer, and believing there might be truth in my statements, requested the continuation of the work and gave it his unqualified support. This placed the work on an official basis. The investigations extended over three months of time and were carried on at considerable personal expense, which was never reimbursed.

PHYSICAL CONDITIONS

From ordinary observations of the geographical features and the arrangement of the breakwaters at the easterly end of the lake, it would appear on superficial examination that the littoral or shore current at Smoke's Creek would proceed to the west of the breakwater limits. It was found on observations of the current that it passes into the openings between the breakwaters, and that under the ordinary conditions existing when the lake is at normal height and when the gales from the west prevail, the American shore waters at the eastward end of the lake hug closely the easterly side of both river and lake. If Buffalo Harbor was a landlocked bay, with but one narrow entrance and no outlet, there would

Fig. 5.—South channel entrance, showing actual currents.

be an ebb and flow, influenced entirely by the rise and fall of the lake level as at Erie Harbor (Presque Isle), Pa. At Erie Harbor when the lake rises the water rushes through the one channel opening into the bay at the rate often of 7 to 9 miles per hour, and when the lake falls it passes out as rapidly, according to the rapidity of rise and fall in the lake. This I know from personal observation. It is merely a question of water seeking its own level. But the condition at Buffalo is very different. We have the terrific outflow of Niagara Falls

exerting its power at the head of the Niagara (a flow of "215,000 cubic feet per second"). This flow is always to the northward—in one direction. The breakwaters act as barriers holding back the water until it reaches the openings between them, when it passes through, as our floats indicated, but not in sufficient quantity to equalize the level, or to make up for the continuous flow to the northward to the falls. Hence the condition is usually constant, even with sudden fluctuations in the water of the lake, which are usually slight.

Fig. 3.—View of south channel in distance from superstructure, Union Bridge.

DESCRIPTIONS OF FLOATS USED

The float consisted of two tin cans (Fig. 15) tightly sealed, each 3 inches in diameter by 6 in length, the lower one weighted sufficiently almost to submerge the upper one so that the wind would not influence it. The lower one was placed so as to float clear of the bottom of the lake, the observations thus recording the average

Fig. 7.—Middle channel entrance to U. S. Harbor. Actual currents.

current—not top or bottom current—of the water through which it coursed. Each float was followed by a policeman in a boat as an absolute necessity to keep track of it, throughout its full course. Many more observations than are depicted on the charts were made, all of which emphasized the fact that the currents follow the courses given in the charts.

Complete detail charts are provided showing the course of the current observations, covering the area influenced by the question at issue. They will be de-

scribed together with the detail of the course of the floats, beginning with those indicating the shore currents at Smoke's Creek, or proceeding from the south, northerly.

Observations were made when the lake was under normal conditions as to stage of water, and with light winds, the condition usually prevailing in the summer season.

To appreciate the import of this work it must be remembered that the generally believed course in a freshet of Smoke's Creek was that it would course out into the lake away outside or to the westerly of the breakwater, as shown on the chart (Fig. 4).

CURRENTS AT SOUTH HARBOR ENTRANCE AND SMOKE'S CREEK

Two floats were used here and placed 100 feet and 300 feet, respectively, from the shore at the mouth of the creek. In the course of five hours they had floated northward about parallel with the shore and about a quarter of a mile from their starting point (Fig. 5).

A float was placed one mile out in the lake from Smoke's Creek, and arranged to take in a depth of 28 feet of water. It passed into the South Harbor entrance, as shown by same chart, and what is significant—within a short distance of the northerly end of Stony Point breakwater. Floats located 200 feet, 500 feet and 1,000 feet westward of the north end of Stony Point breakwater passed into the inner or United States Harbor through the south channel entrance, and in a broad sweep well toward the eastern shore of the harbor (Figs. 5 and 6).

As the mass of water passing eastward through the south channel entrance is very many times more than

Fig. 8.—View of middle channel from roof of Export Elevator.

could possibly pass out of Smoke's Creek even when filled to its greatest capacity in freshets, it is reasonable to believe that material from Smoke's Creek does not pass north of the south channel entrance; also that the character of the water passing along the westerly side of the south breakwater is of same purity as that one mile out in the lake at Smoke's Creek. I have already indicated this by the clinical demonstration of the purity of the water used at Father Baker's establishment at West Seneca, which uses water taken from this part of the lake.

MIDDLE CHANNEL ENTRANCE

Floats of suitable depth placed 75, 150, 500 and 1,000 feet, respectively, westward of north end of the south breakwater passed into the United States harbor through middle channel entrance, and in a wide sweep to mid-harbor, before passing northerly toward the light house pier (Figs. 7 and 8). The conclusion here must be that water coursing along the westward side of the south

OBSERVATIONS NORTHERLY SECTION OF BUFFALO HARBOR
AND HEAD OF NIAGARA RIVER

Here we find a most extraordinary and interesting confirmation (Figs. 9 and 10) of the facts which we are forced by these observations of natural conditions to accept, namely, that no material from Smoke's Creek or Buffalo River gains access to the Niagara River intake under normal conditions of wind and weather mentioned, and, in all probability, under no abnormal conditions with which old lake residents, who have observed these waters for many years, of which I am one, are acquainted.

Float 1 (15-foot depth) started at a point 50 feet westward of the northerly end of old breakwater (red light), instead of passing to the northward, as many would believe, passed eastward and southward, fully 150 feet southerly of the north breakwater.

Fig. 9.—Chart, northerly portion of Buffalo Harbor, showing actual currents and main harbor entrance.

Fig. 10.—View of main harbor entrance from roof of Chamber of Commerce building.

breakwater, even as far west as 1,000 feet from the breakwater, passes into the middle channel entrance, and makes much more remote the probability or possibility of any water from Smoke's Creek ever passing westerly of the breakwaters. But let us pass on to the northerly section of the harbor.

Fig. 11.—Chart of Niagara River at intake. Detail of currents.

The wind at the time was blowing briskly from the east, which was directly against the course of the current, and the float. Mayor Knight witnessed this demonstration. The idea that the wind produces currents opposing the natural flow of water was proved to be false in this case. The float further coursed in a good sweep to the north and east and lodged against the west side of Bird Island Pier as shown on the chart. This might be called the initial official observation, except that I had known of this current from almost the beginning of the construction of this north breakwater, watching it daily in my trips to what was then my summer home at Crystal Beach, Ontario, and studying it for years since; the fact is emphasized that this current always sets from the lake toward the shore and forces the outflow from Buffalo River and the United States Harbor to the eastward; that all septic material from these portions of the harbor is actually driven further

eastward from the intake pier than it was before this breakwater was constructed. Again, I have frequently observed the outflow of Buffalo River in the spring freshets. From any of the high buildings (Fig. 10) the line of demarcation of the muddy water of Buffalo River can be distinctly seen to the east of the clear blue water of the lake. I have called the attention of several engineers of repute to this fact, which they have verified. The great importance of this current on summing up the results of all these factors, which have been questioned by engineers who have made a cursory examination of the question, will be noted.

Float 19 started 500 feet westward of the north end of the old breakwater, was picked up about midway along the westward side of the north breakwater indicating that at that point the current divides, one portion going north and the other south (Fig. 9).

Float 20 started at a point 1,000 feet westerly and at right angles at the north end of the old breakwater. in 37½ minutes was picked up at the intersection of Virginia Street, prolonged westerly, and the prolongation of the old breakwater northerly. From this point it was again started and followed to a point one-half the

over 1,000 feet out into the lake before it could pass the current passing into the south harbor entrance. If it could do this it would have to repeat the performance at the middle entrance, and if such an absurd occurrence could take place it would be necessary for the floating material to jump out at least 500 feet at the north end of the old breakwater to prevent being forced around the southerly end of the new breakwater and be carried northward closely skirting the Bird Island Pier at the region of the intake. And again, as I have shown, to reach the intake such material would have to gain a

Fig. 12.—View of present intake from American shore.

distance between the intake and Bird Island Pier, or 320 feet eastward of the pier. Without giving the course of intermediary floats, which show on the chart, it was found that the one started from the intersection of Jersey Street and the old breakwater prolonged took the course to the center of the intake pier. (The new intake takes the same water). From this it is seen that the intake is supplied by water coming from the starting-point of Float 9, intersection of Jersey Street and breakwater prolonged, and which if carried in the regular course of lake flow from the southward strikes a point over three thousand feet westerly of the north end of old breakwater (red light—Fig. 9).

Now let us see what kind of condition would carry any material from Smoke's Creek to the intake under the conditions of wind and weather cited. If we continue the general course of this current further southward to opposite Smoke's Creek it will be found to be about three and one-half miles out in the lake. Hence, to reach the intake pier, material from Smoke's Creek would have to start about three miles out in the lake to begin with. Taking it as it is, material from this creek floats along the shore, but would have to jump

Fig. 13.—View of intake, and Bird Island Pier intake, the latter the source of epidemic of 1894, costing over 100 lives.

14. View of intake, range lighthouse and Bird Island Pier.

position at least 3,000 feet west of the north end of the old breakwater to reach the intake pier.

That any one could make the statement that material from Smoke's Creek, in the face of such natural conditions, could reach the intake is absurd, but the assertion has been made by sanitary engineers. No one who valued his reputation would do it after knowing the actual conditions of the currents, which through my investigation was first definitely given to the knowledge of the citizens of Buffalo. The strongest argument in favor of my stand in this matter is that in the spring when

the rains poured down, when both Buffalo River and Smoke's Creek were pouring their waters filled with typhoid infection, out into the lake with their fullest flow, no increase in typhoid fever or even in enteric diseases, according to statistics, took place. Had the material from the epidemic district of Smoke's Creek and Buffalo River reached the intake and been pumped into the water-supply, notwithstanding the precaution to boil the water, which was only partially carried out by the people at the time, there would have been a typhoid epidemic such as no large city in the country ever dreamed of, and the prognostications of dire results from the Smoke's Creek epidemic would undoubtedly have been realized. One great point of interest which I believe will make this paper appreciated is the remarkable and wholly unexpected course of these currents, never before studied, and their clear influence in protecting a great city, (through the location of the intake pier by fortuitous decision only, and not from any true knowledge of current conditions based on investigation), from its own infectious factors. The epidemic of 1894, costing over 100 human lives, I may again state proves this point.

Special attention is called to the current passing around the southerly end of the new breakwater. Its

Fig. 15.—Diagram of floats. No. 1 used; No. 2 recommended; No. 3, a form condemned by author as unreliable in light seas and winds.

influence can be observed, as I have stated, any time in the spring freshets from the high elevations of the large buildings overlooking this portion of the harbor. It retains the freshets of Buffalo River and all material coming along the shore of the United States Harbor to the eastward and forces it closely along the westerly shore of Bird Island Pier, and much of it passes into Black Rock Harbor and the Erie Canal. From the Morgan building, in which my office formerly was located, I have observed it hundreds of times.

It was natural that opposition to my views based on the results of these extended and careful observations of the currents should persist even after the result was known. It was held that undercurrents, never known to any lake observer through unknown or never-heard-of wind conditions, carried the infection from both Smoke's Creek and Buffalo River out to the Buffalo intake, and also that the north breakwater aided in carrying infection further out in the lake than before it was constructed. And it is on record by one New York City engineer's report that the waters along the westerly side of the old and south breakwaters is seriously contami-

nated according to his bacteriological reports. I am not entering into any controversy with those who differ from me on this subject at the present time, but present these observations honestly, carefully made, and from an engineering point of view, without triangulation, most interestingly and correctly located and charted.

VALUE OF CURRENT OBSERVATIONS TO THE CITIES ON NIAGARA RIVER RECEIVING THE SEWAGE OF BUFFALO

About the year 1868, prior to the location of the draw of the international bridge (Fig. 11), I assisted in taking triangulation observations of the current of the river for about one-half mile south from and to the bridge site. This work was done at the suggestion of the officers of the Corps of Engineers, U. S. A., to aid in determining the rapidity of currents with reference to the best location of the draw of the bridge and resulted in a change from the proposed location from the center of the river in 36 feet of water to the eastern side in 16 feet of water. It also demonstrated that at this point the currents followed closely the general axis of the river, so that the pure water of the river follows the Canadian shore, and the contaminated water, owing to virtually the entire sewage of the city of Buffalo being thrown into it, the American shore. If the city of Niagara Falls takes its water-supply from the Canadian side of the river at a suitable point relatively pure water should be obtained. This observation may apply to many other cities.

It is to be sincerely hoped that the befouling of our potable water-supplies through sewage thrown into the lakes, rivers and streams of the country will be discontinued, as it can and should be.

24 West Eagle Street.

PRESENT-DAY PROBLEMS AND PROGRESS IN PREVENTION OF TYPHOID FEVER*

WALTON FOREST DUTTON, M.D.
CARNEGIE, PA.

The health of a people is its most valuable asset. This truth has been recognized by most governments of the world. They have found that the virtue of national strength lies, in great part, in the conservation of national health.

The United States government in its battle against malaria, yellow fever, cholera, uncinariasis, and plague, has accomplished much for the common good, but seems to have taken little interest in the prevention of typhoid fever. The first effort of any magnitude in this direction was during the Spanish-American war. The result was a signal, dismal, and disgraceful failure. The camps of Chickamauga, Tampa, Fernandino, Anniston, Mantauk Point, and those in Cuba, were enough to arouse the medical world to the inefficiency of the medical department in the prevention of typhoid fever. The national government's aid in the past twelve years, however, has materially increased, but not to the degree of being of intrinsic value to the people of the country.

It has been, comparatively, a recent procedure for the states and municipalities to take active part in the prevention of typhoid. Rural districts in all parts of the United States and Canada are practically without preventive measures. In northern Canada, during the

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

year 1909, typhoid fever appeared to be generally epidemic, especially in the mining regions.

The preventive measures used are nothing beyond the occasional disinfection of stools and urine with chlorid of lime or bichlorid of mercury, and the boiling of drinking water. Contaminated springs and wells are

Present-day problems, as well as those of the past, concern, first, the individual; second, the community; third, the state.

In considering the individual, we must take his responsibility or importance as a factor in the causation or prevention of typhoid fever. The individual, in

Fig. 1.—The proper method of sanitary construction in rural districts.

Fig. 2.—Improper method of rural sanitary construction.

not condemned, but cleaned out, sprinkled with lime or salt, and used again. Within the scope of my personal knowledge are several dug wells that have been the source of typhoid for twenty years. Any reference to them, however, as a means of infection, is met with apathy on the part of the consumers.

health, may be the means of carrying and distributing typhoid germs, and, in fact, may be the sole origin of the bacilli.

We know with what ease he may carry the bacilli by contact, food, etc., and, on the other hand, through some error of diet or irritation the digestive

tract, the colon, paracolon, or the paratyphoid, may, I believe, generate typhoid.

The individual comes to be a factor in the prevention of typhoid through a due process of education and law. He must be educated to know the nature of typhoid fever and the processes by which bacilli may be disseminated. Laws concerning preventive medicine and

Physicians should keep a record of all typhoid cases and systematize the record of carriers that due prophylaxis may be secured. The healthy, as well as the unhealthy germ-carriers, may be trained in the importance of prophylaxis, and thus reduce the source of danger to a minimum.

In every case, systematic search should be made for the source of infection, and the finding of bacillus-carriers will prove an important adjunct in the prophylaxis of typhoid fever. The prevailing idea that healthy carriers cannot be brought under supervision like other carriers is worthy of serious thought. The time is near at hand when the community and the medical profession will have the problem solved for their ready perusal and use.

The state is the great supervisor of preventive medicine and public health. In its hands lies the governing power, which, if duly exercised, can eliminate, not alone the major, but the minor sources of diseases. In Pennsylvania, the department of health, under the efficient supervision of Dr. Samuel G. Dixon, has typhoid, as well as other diseases, under practical control. From this department, means of communication is had, through its police system, with every dale, hamlet, and city, within the borders of the state. Within a few hours, infectious and contagious disease, in the most remote part of the state, is reported to the department of health and receives prompt attention.

Our present knowledge of typhoid is limited to the following factors as sources of infection; water, food, personal contact with the diseased individual and insects.

Fig. 3.—Concrete spring cover.

public health become more forcible through the individual's hearty cooperation.

The problem of the community is somewhat more difficult than that of the individual or the state. An epidemic may present many sources of infection and the situation may be complicated by the restriction of the authority of the community.

A commendable procedure, however, is the isolation of bacillus-carriers until the microbes can no longer be found in them. Precautions should be taken that the discharges of the carrier will not be a source of danger to his family, and to others. The individual is warned of the danger of the dejecta, urine, kissing, coughing, etc., and taught the processes of rendering these harmless. He is also to be instructed to wash his hands after defecation, and before handling clothing, food-stuffs, or vessels used for drinking purposes. This warning applies to the healthy, as well as the unhealthy bacilli carriers. A very great deal of responsibility rests on physicians, nurses, and hospital authorities. It requires tact, skill, and ingenuity to impress on individuals especially, the gravity of the disease, without causing undue timidity on the part of the persons involved.

The supervision of carriers employed as teachers, nurses, cooks, or employes in bakeries, dairies, restaurants, saloons, etc., should be rigid, for the community has a right to insist on the isolation of such carriers, until such a time as they are free from the germs. Hospitals should regulate their subordinate personnel, keeping careful record of all known bacillus-carriers, and using every precautionary measure to prevent contamination by instruction and enforced cleanliness.

Fig. 4.—Concrete cess pool or privy vault of two compartments.

A great deal of progress has been made in eliminating water as a factor in our large municipalities by filtration, or by supply from large fresh-water lakes and streams.

The water-supply in small towns and rural districts presents a problem of more difficult solution. I believe, however, that this factor may be overcome by proper sanitary regulation and legislation enforcing the protection of wells and springs. (Fig. 1) All wells should be drilled and the supply should be from depths beyond all

possible contamination by surface or fissure water. This may be best accomplished by casing the well to or on a stratum of rock or shale which is impermeable to surface, subsoil, or fissure water, and above the supply of water to be used for drinking purposes. A well not cased in this manner may be protected by a wall-packer. It is advisable, whether using a wall-packer or casing on the shale or rock, to run four feet of tar around the bottom; and above the tar, three feet of cement, or vice versa. The top of the casing should be protected with a casing-head, and the pump so adjusted that it will be both water-tight and air-tight. If, for any reason, the well must be dug, the tile (rough stone should never be used to wall a well) should be put down to an impermeable stratum, the bottom protected in the same way as the drilled well, each joint cemented thoroughly and the top protected by a concrete curb, as it keeps out the surface water and is easily cleaned.

The pathetic inscription of "the town pump" might be written as an epitaph on many a tombstone. The vine-covered spring where the wayfarer's thirst has been quenched and the rock-walled dug well are landmarks of the dark ages of sanitary science. The poetical "moss-covered bucket" has held a beverage deadly to thousands of human beings.

It is therefore time for a change from the ancient custom of placing dwellings, barns, privy vaults, etc., in such a location that they will drain into the spring or well, either over the surface, or through the soil, or permeable stratum (Fig. 2). Springs which may possibly be contaminated should be condemned, or they should be protected by cement or brick (Fig. 3). The

Fig. 5.—Perfection box closet.

shield or covering should be inserted into the surface far enough to shut out contamination from local sources. The basin of the spring may be easily constructed so that it can be cleaned at any time.

Municipal sanitation has taken a step forward in disposal of garbage. Seattle, Washington, Milwaukee,

Wisconsin, New Brighton, Long Island, Vancouver, British Columbia, and Westmount, a suburb of Montreal, have destructors in successful operation. The reduction method, used by Cleveland and Columbus, Ohio, seems to be profitable and efficient. The examples set by the foregoing cities should be followed by all other American towns and municipalities. Rural districts,

Fig. 6.—Well which has been contaminated twenty years.

by the use of metal cans and wagons, may accomplish the same end, in an unobjectionable and sanitary manner, if instructed and compelled to do so.

The care of feces and urine presents another problem for rural districts. This problem can be effectually met in three ways.

The first way is by the construction of a double compartment, reinforced concrete cesspool or privy vault

Fig. 7.—Drainage from house, barn and closet toward spring.

(Fig. 4). The cesspool or vault should be so built that only one compartment is in use at one time, thus providing for the disinfection and cleaning of the other.

The second is by the construction of a perfection box closet (Fig. 5). This closet may be so constructed as to be perfectly sanitary, allowing for free ventilation,

providing for disinfection, and screening from insects.

The third is by the use of a closet in which the stools and urine are sterilized or disinfected before being discharged into soil-pipe or drain. All railroad cars and vessels on bodies of fresh water should be provided with closets that disinfect and sterilize the stools and urine before discharging them.

The present method of constructing cesspools and privy vaults is a great error in so far as it pollutes the soil in the immediate vicinity, to say nothing of the

and other food on which flies and other insects breed should be kept in screened or other insect-proof receptacles. As to the breeding and destruction of insects, the Bureau of Entomology issues literature, which, if the instruction is followed, will in due time eliminate this factor.

Vaccination against typhoid fever is practically in its infancy, yet, I believe, in due time, it will be quite effective and valuable.

I believe that the following provisions should be embodied in state health law: The state should be the supervisor of all water-supplies used for drinking and cooking purposes. It should specify, at all times, from

Fig. 8.—Proper location of well with reference to drainage. Privy vaults marked X.

Fig. 10.—Insanitary location of well, cistern, privy vault and stable within twenty feet of each other.

Fig. 9.—Improper location of well with reference to drainage.

drainage to some distance from the cesspool. The seed of disease that is sown in the soil and the subsoil to-day will grow and be reaped in the harvest of disease and death to-morrow.

The law should be so stringent as to compel all patients, who have had typhoid, to carry some efficient germicide that when they urinate or defecate in promiscuous places, the excreta may be rendered harmless.

Much has been said about insect carriers of typhoid, and the best method of prevention of breeding. Manure

which sources they should come, how they should be protected, and condemn all sources deemed detrimental to health. It should be the duty of the state to enact and enforce such laws as may seem fitting, relative to the

Fig. 11.—Insanitary conditions found in small towns and rural districts. Privy vaults marked X.

disposal of urine and feces from typhoid patients or bacilli carriers. It should be the duty of the state to specify how closets may be constructed on trains and vessels on bodies of fresh water, for purposes of disinfecting stools and urine. The state should specify, in given terms, how springs are to be protected and cleaned; how wells are to be drilled or dug, and protected from contamination. The state should hold equally responsible the individual, property-owner, attending physician, hospital, or whosoever may be found

guilty of violating any hygienic or sanitary rule, which will in any manner, whatsoever, disseminate typhoid fever infection. All physicians, hospitals, or those having supervision over typhoid case or cases, should systematize their records in such a manner that carriers may be traced, isolated, and cared for until such a time as they may be free from typhoid bacilli.

409 Fourth Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. DUTTON AND FELL

DR. H. W. HILL, Minneapolis: Dr. Dutton spoke very strongly about the question of typhoid from wells. I cannot speak for any other state than Minnesota, but I know that typhoid from wells is very uncommon in that state, probably for the reason that the character of the soil is such that the contamination is filtered out before it reaches the well. Our rural typhoid is practically never from wells in our state. Our well typhoid has been, as a rule, from the public wells of large communities infected very seriously with pollution of various kinds carried directly into them.

DR. C. HAMPSON JONES, Baltimore: Baltimore is considerably interested in the control of typhoid fever. In a résumé of the subject for a period of four years, which was published in our annual report of 1907, I mentioned the ten possible sources of typhoid fever in the city. Contrary to many excellent authorities, I believe that a great deal of our fever comes from the pollution of the water supply. The characters of the outbreak of typhoid fever due to milk infection are so peculiar, so clearly defined, that it is quite easy, I think, for us to detect practically every milk outbreak. In one there were 157 cases on one man's milk route; in another about 58 cases, and there were three or four others, which fortunately were checked in the very beginning of the outbreak, which produced only a few cases. We have followed out also the typhoid carriers, and we have had two very interesting cases. One was in a home for young women. The woman in charge of the pantry—of the foodstuffs—was discovered to be a typhoid carrier, after there had been fourteen cases of typhoid fever in this place. We excluded the possibility of the milk being infected, and also the water supply in that special locality. Dr. Stokes, our bacteriologist, followed out two carriers lately in a convent where there was a laundry; in it were a large number of colored girls. Two sisters in charge of the girls were the carriers, and the curious and interesting part of it was that there were two distinct outbreaks—one of paratyphoid fever and the other of pure typhoid. One sister was a carrier of the typhoid organisms; the other sister was the carrier of the paratyphoid; the children associated with each case developed typhoid fever according to the sister in charge of them.

In Baltimore we are about to perform an experiment on a great scale. We are putting in a sewerage system including the entire city. We will in a few years do away with all privy wells, of which we now boast in the neighborhood of 70,000. Just previous, however, to the doing away of these privy wells, the drinking water will be filtered. This will enable us to determine how much, if any, typhoid fever was due to both and to each.

DR. LISTON H. MONTGOMERY, Chicago: There seems to be a good deal of difficulty in taking care of the welfare of the people in public health matters in certain communities. May it not be due frequently to the fact that a layman has been appointed as the official health officer? I think this condition prevails in some portions of the northern states as well as in the South. People are not prone to look on a layman as very much of a medical scientist, especially when it comes to the matter of pollution of well waters, cisterns and rivers and streams, or in the matter of the eruptive diseases, and do not respect his opinions, and therefore may be careless in carrying into effect sanitary measures in detail.

DR. W. FORREST DUTTON, Carnegie, Pa.: I think it is a grave mistake on the part of the municipalities and the

health officers in rural districts to countenance the pollution of soil. Some of our most eminent sanitarians are working on the question of soil pollution year after year, not alone with typhoid but with other diseases; Dr. Stiles, I think it is, has pointed out to us most forcibly the effect of soil pollution; and in most of our northern states, especially those that have been settled for two hundred years, soil pollution is a serious problem that will remain with us as long as we will countenance these open privy vaults. I believe that the state of Pennsylvania has caused to be constructed within the last few months privy vaults that are to be bricked up about half way, and then are to be cemented the rest of the way up with an ordinary covering over the vaults, and has prohibited the discharge of sewage into certain streams. I think that is a grave error. If they are going to compel the citizens in the rural districts to construct privy vaults, why not erect them properly, so that there will not be this pollution of soil that has been going on for years? We have regular epidemics of typhoid fever which may not be due to the water originally, but to drainage from privy vaults into the soil. According to a great many eminent authorities these bacilli are viable for an indefinite period, possibly multiplying in the soil, and as far as Dr. Hill's reference is concerned, Minnesota is comparatively a newly settled country, and a hundred years from now if they allow this soil pollution to go on they will have the seeds of disease sown that will be reaped by future generations.

SURGICAL MISTAKES IN INFANCY AND CHILDHOOD*

SAMUEL WALTER KELLEY, M.D.

CLEVELAND

Not all the mistakes here related are of my own making, for which I am duly thankful. But many of them or their results have come under my own observation. Others have been related to me by my colleagues.

The cases are, for the most part, not merely such as would in the adult present difficulties in diagnosis or in treatment; but they are such as are met only in the surgery of infancy and childhood, or in these periods of life present peculiarities when compared with corresponding conditions in the adult, and lead the practitioner unfamiliar with them into error.

I have taken especial pleasure in presenting the illustrative cases furnished by my colleagues, because they show that the idea that mistakes in the surgery of infancy and childhood are altogether too common is entertained not by myself alone; they show also that the condition of ignorance of children's surgery is not confined to any one part of the country.

NECESSITY FOR CAUTION IN OPERATING ON CHILDREN

Take for example the following case, related to me by Dr. Zahorsky of St. Louis: An infant 5 days old had an enormous cephalematoma, which was aspirated by a physician, but promptly refilled. A surgeon then made an incision and packed the cavity with gauze. But in spite of all measures slight bleeding continued until the baby died. There was no history of hemophilia and none of the doctors considered the baby a "bleeder;" but it taught them a lesson they should have known before—for such cases are not uncommon—namely: never to operate on cephalematoma unless, later on, an abscess results, which must be drained.

A baby 3 days old with a hare-lip was operated on, losing some blood, of course, at the operation, and suffered from severe secondary hemorrhage, from which it

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

died on the sixth day. This illustrates the point that, since there is no necessity for operating at once on a hare-lip, a child should never be operated on for this condition during the first few days of life, when the tendency to hemorrhage is so pronounced. The same is true of phimosi, a spina bifida or any malformation not immediately endangering life. In anorectal imperforation, atresia of the esophagus or the like, it may be necessary to risk immediate operation to save life.

A child of 4 years, in good general health, but with a cleft palate, was operated on in the presence of a purulent rhinitis; the result was failure of union and sloughing of a portion of the flaps. The lesson from this mistake is obvious. No such patient is fit for operation until the adjacent tissues have been rendered free from infective inflammation.

A boy of 5 years with cleft palate came to a dispensary and, although he had a cough, was somewhat hastily put through an operation for cleft palate. The cough proved to be whooping-cough. It was not very severe, but it was persistent and had the spasmodic paroxysms of that disease, and it tore out some sutures. Bronchitis followed the operation, perhaps favored by the hemorrhage, bronchopneumonia supervened on the bronchitis and the boy succumbed in the third week of his illness. It was a mistake to operate on that child with a cough.

Dr. Zahorsky relates a similar case in a girl of 4 years operated on for cleft palate, by mucoperiosteal flaps and staphylorrhaphy, with chloroform as the anesthetic. A mild bronchitis was present at the time of operation, but grew worse, developed into bronchopneumonia and resulted in death two weeks after operation.

It is a mistake to perform any similar operation on a child in whom elevated temperature indicates the possible onset of an acute illness, and especially is this true if it is a child who is subject to convulsions on the slightest provocation, for convulsions are disastrous to the results, not only in operations on hare-lip and cleft palate, but in many postoperative conditions which will readily occur to mind, and convulsions are a great deal more likely to supervene in a child than in an adult.

Dr. Cattermole states that he has several times seen operations performed for adenoids and enlarged tonsils when the child was in no fit condition, having acute pharyngitis or bronchitis at the time of operation. Dr. Cattermole also relates the case of a child of 5 years with appendicitis gone to abscess. After evacuating the abscess the surgeon persisted in removing the appendix, and the child died. Dr. Cattermole considered that it would have been better merely to drain the abscess for the time being, and he was right.

DANGER OF DELAYING OPERATION

I shall never be able to forget my first case of foreign body in the larynx. That was more than twenty years ago, but it remains indelibly impressed on my memory:

A girl of 6 years was brought from the country to my clinic at the dispensary. She thought she had drawn into her windpipe a piece of the kernel of a hickory-nut. There was some dyspnea which was worse in paroxysms with coughing, and some aphonia; but, again, at times the breathing would be easy and comfortable. The girl was quite able to walk about. I placed her in the hospital intending to operate. But a distinguished laryngologist, and a senior surgeon on the staff, both my superior officers in the institution, advised against operation. The laryngologist inspected the throat on several occasions with laryngeal mirrors and attempted with laryngeal forceps to remove the foreign body. On failing to do so he always postponed operation in hope of better luck with his

fishing tackle on the morrow. On the fourth day the foreign body suddenly shifted its position and the dyspnea became extreme. The house physician hastily summoned aid. I was the first to arrive on the scene and in a moment had opened the larynx and extracted the nut-kernel. The child took one easy breath, but that was her last. She was exhausted. That child could have been saved by timely operation.

It is a mistake to rest and wait with a foreign body, however quiet, in the larynx or trachea unopened. There is no safety until it is removed.

MISTAKES IN DIAGNOSIS IN CHILDREN

Many a case of retropharyngeal abscess has been mistaken for tonsillitis. Less frequently, a passive edema of the pharynx, an angioma, a mucous cyst, or a gumma has been mistaken for an abscess.

In one patient 2 years old, a few weeks after diphtheria, when nasal intonation occurred, and difficulty of swallowing, the fluids returning through the nose, I was about to make a diagnosis of postdiphtheritic paralysis. But, on exploring the throat, I found retropharyngeal abscess, and close examination revealed the fact that both paralysis and abscess were present at the same time. Postpharyngeal abscess may readily be mistaken for paralysis or both may exist together.

Retropharyngeal abscess may be mistaken for uremia. The following case is contributed by Dr. Le Grand Kerr:

A boy of 3 years, afflicted with postscarlatinal nephritis, suffered from indefinite symptoms for three days, but with such marked prostration and mental dulness that the onset of uremic convulsions was feared. Dyspnea became more and more marked. During all of this period the child refused to partake of food. It was difficult to collect the urine and that was given as the excuse for its not being examined. Mouth-breathing finally became established and there was a free flow of saliva from the mouth. The prostration was the most marked feature of this illness. On the fifth day Dr. Kerr saw the child and an examination of the throat revealed, when the tongue was depressed, a very slight bulging of the posterior pharyngeal wall. Digital examination then confirmed the suspicion of abscess. Stenotic breathing was a noticeable feature of this case.

Quite recently, I was called by Dr. B. to see a little girl of 4 years. She had always been a delicate child. The present illness had lasted five weeks. It had begun as a pneumonia, and then developed an undoubted nephritis, with abundance of albumin and casts in the urine. The pneumonia and nephritis had subsided. The urine cleared up almost entirely. Some cough remained. But the child continued to have fever up to 102 and 103 or more; complained of pain in the right hypogastrium and loin, and had become so emaciated and reduced in strength that her death was expected from day to day, and from night to night. The attending physician had called in counsel one of the most noted practitioners of the city, who had made an exhaustive examination. Appendicitis, among other diseases, was suspected and excluded. It was thought likely a stone in the kidney was producing the pain and the fever; and it was advised that the child be transferred to hospital and examined with the x-ray for the purpose of detecting the stone. After hearing this history I examined the patient, with the result that I drew off with a trochar several ounces of pus from the right pleura, drained the cavity by a free incision the next day, and the child made a gradual, but uninterrupted and complete recovery.

It seems almost incredible that such a mistake could occur in the hands of competent men. This is explained by the fact that they were men more accustomed to handling adults than children. The severe pain in the hypogastrium and loin misled them. A pediatricist would have known that the pain of pleurisy in a child is just as apt to be referred to the abdomen as the chest; that

in the small body of a child a tympanitic percussion note from the stomach or intestines may be so transferred to the chest as to mask the dulness of an effusion or a consolidation, and that stone in the kidney of a child is comparatively rare, while purulent pleurisy is very common.

Pneumonia and pleurisy, especially, because of the pain associated with them, which is as frequently referred to the abdomen as to the seat of the lesion, have in numerous cases, when located on the right side, been considered as appendicitis. So deceptive may these cases be that a diagnosis of appendicitis should never be made, or at least a decision to operate never arrived at, until the chest has been most thoroughly examined by one accustomed to physical diagnosis in children. Of course, it is to be remembered that chest and abdominal inflammation may co-exist.

Dr. Elterich of Pittsburg considers empyema and intussusception the two surgical conditions which are most apt to be overlooked or to lead to mistakes in diagnosis.

Dr. Hollopeter states that the overlooking of a remaining effusion, which, as is well known, is apt to be or to become purulent, is the most common error he meets. Next in frequency he places neglected otorrhea requiring surgical intervention.

In this connection Dr. L. K. Shaw cites three cases in which diagnosis of appendicitis was made when the trouble was pneumonia.

Dr. Van Derslice recently related to me a case of pneumonia in an infant at which he arrived just in time to find the physicians, already in consultation, discussing the advisability of operating for intestinal obstruction.

Dr. E. H. Bartley of Brooklyn refers me to a case reported by him,¹ in which he assisted at an operation for appendicitis and found the ileocecal valve plugged with lumbricoid worms.

Speaking of wrong reflection of pain by children reminds me that I have several times seen a persistent and troublesome abdominal pain treated by all sorts of attention to the digestive tract, when the real cause of it was caries of the spine. The spinal nerves near the lesion were irritated and caused the pain, but this was referred to the point of distribution of the irritated nerves in or on the abdomen. Meantime, the serious tuberculous inflammation in the vertebræ was neglected, because no curvature had yet appeared and the physician failed to recognize the early signs, which are quite as distinctive. A lateral curvature may cause abdominal pains, but when it does the curvature is usually so marked that it could scarcely be overlooked. Again, it is not uncommon to see a spinal curvature due to rachitis mistaken for an angular curvature and the condition aggravated by loading the weak frame with a plaster jacket or a brace. This is a quite unpardonable mistake.

A case which occurred but a couple of months ago illustrates a typical mistake and brought freshly to my attention a class of cases in which mistakes too frequently occur:

Marion P., a well-grown, beautiful babe of 9 months, had been sick ten days at the time I was called in consultation. The history showed a sudden onset of the illness, with pain, evidently paroxysmal, judged by the screaming spells induced, with vomiting which, on the following day, brought up greenish fluid, and with frequent small bowel movements with straining which discharged a small amount of fecal matter together with mucus and blood. A diagnosis of gastro-

enteritis was made by the attending physician and the usual remedies used. The acute character of the symptoms abated, but did not cease. The diagnosis was modified to ileocolitis, which might run a course extending over weeks. But, as the second week advanced without cessation of the symptoms, the parents became alarmed and requested counsel. With a dim suspicion of appendicitis or of intussusception in mind a general surgeon was called in. The diagnosis of ileocolitis was confirmed, intussusception being considered, but excluded because of the presence of fecal matter in the discharges, and because of the length of time the illness had continued without fatality. On seeing the case, the first thing that struck me was the facial expression of the infant, a peculiar expression of distress and hopelessness that the face assumes in cases of intestinal obstruction. On hearing the history—the sudden on-set, the paroxysmal character of the pain, the amount of the blood passed, the severity and persistence of the symptoms without a corresponding height of fever,—I was almost convinced that the condition was one of accident, rather than of disease. Then, in spite of objections, I insisted on examination under anesthesia and found what I had expected to find, namely, a tumor, that peculiar crescent-shaped tumor characteristic of the intussusception. It was lying deep, above and to the left of the umbilicus, with its concavity toward that landmark. It could be easily moved about and picked up in the fingers, and handling it brought on a paroxysm of pain and tenesmus. There needed nothing to complete the diagnosis. Within the hour the bowel was completely reduced by measured aerohydrostatic pressure, and the babe promptly recovered.

I have seen a case of intussusception of as much as three weeks' standing, with the mass descended as low as the rectum and even projecting through the anus, treated for dysentery together with rectal prolapse. My notes contain reports of several cases which had been mistaken for either dysentery or prolapse of the rectum.

Dr. J. Ross Snyder of Birmingham furnishes the following case:

The patient was a 3-year-old boy. After being ill with bowel trouble for several weeks, the patient awoke screaming in the middle of the night, complained of great pain in the abdomen and vomited very often. Next day he had dysentery, so called, which was checked by bismuth, but the movements still contained mucus and pus. The boy complained continually of pain in the abdomen and could not sleep. This persisted for eight days, when a tumor in the abdomen was discovered. After two days more Dr. Snyder was called in consultation with the family physician and a surgeon well known locally, who had agreed on a diagnosis of a diseased kidney, because the tumor was near the region of the right kidney and the boy cried out at each urination. Dr. Snyder convinced his confrères that the trouble was intussusception. The patient died ten hours after an operation which, if performed earlier, would probably have saved his life.

Dr. Snyder relates also the case of a babe of 16 months with a gastro-intestinal infection in which the conservative diarrheal process was not established, but in which the toxemia had paralyzed the bowel. This case was diagnosed by a surgeon as intussusception.

Dr. Cattermole relates the history of a case in which he made a diagnosis of sarcoma of the kidney in a young child. A surgeon was consulted, who advised against operation, not from any unusually conservative spirit, but because he did "not know what could cause such a condition in a child." Autopsy revealed the sarcoma, which evidently originated, as is often the case, in the suprarenal gland.

I cannot recall the number of times I have seen children wearing a truss on a hydrocele under the supposition that it was a hernia. To be sure, hydroceles of the cord or of the canal of Nuck, in which this mistake

1. Bartley, E. H.: Arch. Pediat. 1898, p. 272.

is usually made, occupy the position of an inguinal hernia, yet there is little if any excuse for a mistake in the diagnosis, if only the possibility of these forms of hydrocele be borne in mind, as the diagnostic signs are usually distinctive. I have seen a truss worn on undescended testicle supposed to be hernia—a blunder quite inexcusable, in view of the obvious diagnosis of the latter condition.

A few days ago a case of a new-born babe was referred to me with the statement by the physician that the penis was imperforate and that the babe had passed no water all the day of his birth. The physician had tried to find the urethra by making a puncture with a narrow-bladed bistoury through the glans in a longitudinal direction, but his effort was in vain. On examination it proved to be one of those not infrequent cases of hypospadias in which the urethra ends, a half inch or more posteriorly than it should, in a membrane so thin that its margin is invisible. In this case a small probe, directed in the proper direction, readily located the attenuated margin and found the urethra, which was patulous throughout, and a small catheter was passed, a small amount of urine being found in the bladder. The child soon urinated naturally and of course no operation at all was necessary. Through the employment of a little diplomatic talent the almost ludicrous blunder, which might have ended in several varieties of trouble, was prevented from becoming obvious to the family.

It is far too common to find hip-joint disease mistaken for disease of the knee-joint, because of the pain referred to in the latter location. It is not at all unusual to find a knee stained with iodine or blistered or abraded by the use of liniments, or even to find it encased in a splint, for a trouble located as far away as the length of the femur. And this not merely in the hands of the laity, but, I am sorry to say, sometimes under the advice of a physician. The disease supposed to be affecting the knee-joint in these cases is usually rheumatism. And, on the other hand, many a case of tuberculosis of the knee-joint and of some other joints, as well as cases of acute arthritis and of acute osteomyelitis, have gone on to irreparable damage while being treated under this mistaken diagnosis of rheumatism. As I have before remarked, "the scapegoats of puzzled medical pediatricians are teething and worms; the scapegoat of joint and bone surgery in childhood is rheumatism."

Dr. Le Grand Kerr contributes the following report:

A male infant, 18 months, was taken suddenly ill with high fever which fluctuated almost hourly and was accompanied with marked prostration and nervous symptoms. The left lower limb was held rigid, and severe pain was elicited about the knee-joint and ankle. There was redness, but no swelling. On the third day of such symptoms, the infant was sent to the Williamsburg Hospital with diagnosis of rheumatism. Examination now showed some swelling about the knee and ankle as well as redness and severe pain on handling. Fluctuation was detected on the fourth day. Complete operative procedure brought relief.

The following, also contributed by Dr. Kerr, illustrates how easily syphilitic periostitis may be mistaken for rheumatism:

A boy, 5 years of age, was sent to my service at the Seney Hospital (1909) with diagnosis of acute articular rheumatism. The knee was much swollen and reddened, and very painful. Temperature slightly elevated (100.2 F.) The child had been subject to frequent attacks of sore throat. Examination showed the knee-joint swollen, reddened and painful in front and at sides, but at back of joint slight fluctuation was

elicited. Incision was accompanied by free flow of pus. There was slight redness and swelling about one wrist and incision released a small amount of pus. With specific treatment recovery began at once.

Dr. Charles Douglas of Detroit reports several interesting cases in which scorbutus was mistaken for other conditions. The first case had been treated by one physician for rheumatism, and then by another physician for fracture of the neck of the femur or a dislocation, and, after plenty of manipulation, the limb had been put up in splints. Another patient with scorbutus presented two bluish swellings, one on the back of each hand. A surgeon was consulted and advised operation for their relief. Another surgeon saw them and acknowledged ignorance of their character. Both of these patients recovered quickly on orange-juice and raw milk.

A babe returned to Detroit after a summer in the Lake Superior region. It had staphyloma of both eyes, one being very large and ready to rupture. The oculist treated it locally and gave a hopeless prognosis for one eye, but hoped to save the other. When the case came under the care of the pediatricist raw food and orange-juice worked an immediate improvement, and a final cure, though leaving a large scar on the worst eye. The oculist was delighted and acknowledged to the pediatricist that the latter had saved the eye.

Dr. Douglas relates another instance in which a pronounced case of rickets was treated for rheumatism.

Dr. Shaw writes: "I have seen a surgeon excise a tumor on the leg which turned out to be a large blood-clot due to scurvy. I have seen a baby entered in the surgical ward with a diagnosis of sarcoma of the shoulder, which was infantile scorbutus, and cleared up in a few weeks with orange-juice."

Two boys, from their second or third years on, showed extensive contusions from any slight bump and when the eighth year was reached they suffered with joint swellings, the knees and elbows being most affected. These joint swellings would last from ten to fourteen days accompanied with pain, loss of function and discoloration. After repeated recurrences the joint attacks disabled them from all work or exercise, since extension of the joints was impossible by reason of the tenderness and swelling. When the elder brother was 18 years of age a surgeon, disregarding the history of the cases and the clinical condition which should have been sufficient to warn him of the presence of hemophilia, made the mistake of undertaking an operation. He tried to straighten the right knee by tenotomy of the hamstrings. The hemorrhage was not profuse at first, but it was most obstinate, and the first dressing was left on three days. Removal of the bandages was followed by renewal of hemorrhage which took place both externally and into the tissues subcutaneously. And this hemorrhage continued in spite of all efforts to control it until the eleventh day after the operation, when he died. (The younger brother of this boy died in his seventeenth year of a spontaneous hemorrhage).

Another mistake by another surgeon occurred in a connection of the same family, as follows: A nephew of these two boys manifested in his second year the swellings and discolorations of joints and the tendency to acquire contusions, characteristic of hemophilia. When he was 2 years old a slight cut on his finger bled four days. When 4 years old he accidentally bit his tongue and the wound bled three weeks. A small punctured wound on his chin bled nine days. When a few years older, a small cut on his brow received while coasting was repaired by two sutures. Six days later a large secondary hemorrhage occurred. Now a surgeon was called in. He heard the history of the case, but said he "didn't believe in bleeders"; that the trouble was all because people didn't know how to control hemorrhage; and that some doctors also were afraid of a little blood. In his opinion this hemorrhage

was caused by a vessel, deeper in the tissues, wounded but not completely divided. He enlarged the wound to search for the wounded vessel. The bleeding which followed could not be controlled by ligatures, sutures, or even by forceps which were left attached to the wound, but which broke away with the sloughing tissues, bringing the ligatures and the sutures with them. All known styptics were used but the blood continued to ooze during five days. Then, when the boy was nearly dead it ceased spontaneously, and the wound healed leaving a frightful scar. It is to be hoped that ere this the surgeon realized that he had made a mistake in not paying heed to the history, and in not believing in "bleeders."

Syphilitic osteochondritis, sometimes called osteochondrosis or perichondrosis or epiphysitis, will in rare cases cause a separation of the epiphysis from the shaft, and will produce the lesion so promptly and unexpectedly that it is mistaken for a traumatic separation. In more instances this affection has been mistaken for rheumatism or for scurvy. As an instance I will cite a case from Dr. Kerr:

A female infant one month old, suddenly developed inability to move one lower limb. The parents denied history of syphilis and the infant did not exhibit any of the usual manifestations of syphilis except a slight, but persistent rhinitis. As sterilized milk had been used from birth, the diagnosis was made of scurvy. When Dr. Kerr saw her in consultation, the left lower limb was immobile and the infant screamed at the slightest touch. A slight swelling was noted at the epiphyseal line. When direct questions were avoided and the history taken cautiously as to events in the lives of the parents, the history of syphilis was established. Later this infant exhibited many of the other manifestations of syphilis.

Traumatic separation of an epiphysis is notoriously apt to be mistaken for a dislocation, which it much resembles. This mistake occurs more often in injuries at the elbow than at any other joint in the body.

Zahorsky notes a case in which a periglandular edema (accompanying scarlatinal adenitis) was mistaken for abscess and was lanced with the expectation of discharging pus. But no pus was found. I am certain a number of us have seen the same mistake made. I certainly have, on several occasions.

Dr. Le Grand Kerr reports the following: A boy of 3 years was taken suddenly ill after a fall, with fever, vomiting and diarrhea, and within twenty-four hours it was noticed that the child did not move the arm. The general symptoms cleared up in four days (evidently owing to digestive disturbance following the shock of the fall), but the inability to move the arm persisted. In consultation on the sixth day, examination revealed a fracture of the clavicle. This illustrates a mistake which is very frequently made.

OVERESTIMATING VITALITY OF THE INFANT

It is a common mistake to overestimate the vital power of an infant and to undertake to put it through an operation too severe for it to withstand—such an operation for instance as that of forcing together the sides of the cleft in cleft palate when performed on a weakly young infant as in the Brophy operation. The chances of death following this procedure are far too many to justify it in the great majority of cases. Another example is that of rib resection in a weakly child of less than 18 months for empyema. A third instance is extensive resection of bowel in intussusception.

JUDGMENT IN USE OF SURGICAL PROCEDURES

But for the fact that it would consume too much time, I could give details of cases to illustrate the fact that often the administration of an anesthetic in an infant

or young child with bad digestive organs may, by the nausea and vomiting it produces, lead to inanition, resulting ultimately in death, days or even weeks after the anesthesia. The anesthesia and the operation may at the time have been perfectly safe and pronounced successful, but it was a mistake to excite the gastric difficulty by an anesthetic in a patient thus predisposed. A good illustration of this point is the following from Dr. Zahorsky:

Twins, 2 months old, artificially fed, were suffering from clubfoot. They were operated on, chloroform being used for anesthetic. Following the operation, vomiting occurred, followed by indigestion and atrophy. Both died about five weeks after the operation.

The same observer related to me the following instructive case:

A boy, aged 7 years, had an osteomyelitis of the left tibia which resulted in denudation of almost the entire bone and extensive necrosis so that the lower two-thirds of the shaft had to be removed. The wound healed, and subsequently the surgeon attached the upper end of the fibula, which had remained sound, to the remains of the tibia. The result of the operation was very good. But three months later it was found that the tibia had been entirely reformed by its periosteum.

Moral: The surgeon should have known that this spontaneous repair was likely to occur. Thus the osteoplastic operation was not only entirely unnecessary but the outcome of the case would have been better without that operation, if only time had been allowed for Nature's reparative work to take place.

The cases are too numerous to count in which mistakes have been made in the employment of antiseptic solutions in common use in surgical practice, but too strong and irritating for the delicate texture of the integument of the young. Ordinary solutions of mercuric chlorid used in moist dressings will often produce a dermatitis and, in the use of phenol in strong solutions or over large areas, phenol poisoning has not infrequently occurred.

Twice within the past five weeks and many times before, have I seen the mistake made of dressing an extensive scald or burn too hurriedly for strict antisepsis and without an anesthetic.

I think that in these days of antiseptic surgery, scalds and burns are more frequently badly dressed than any other kind of wound. An extensive scald or burn is a serious injury in a child, and even a small one may become infected and give rise to serious results. An anesthetic should be administered to relieve the suffering and diminish the shock, and then the wound should be as thoroughly cleansed as if it were an extensive laceration, and the chosen dressing applied. Then the case will probably progress as a clean wound instead of an infected, poisonous and vile-smelling one, as is too often the case, probably ending with toxemia with tetanic symptoms in about the third or fourth week.

It is a mistake to suppose that anesthetics are without danger in cases of infants and children. Three times in my life I have encountered such knee-shaking experiences as have given me a very wholesome respect for the dangers of anesthesia in children. It is true that the heart and kidneys of the young are less likely than those of their elders to be diseased, and that ordinarily children bear anesthesia better than their elders, with less nausea, from which they more quickly recover; but they do not well endure prolonged anesthesia; and the danger of sudden failure of respiration or of the heart is a very real one.

A mistake one not infrequently sees in visiting various clinics and operating-rooms is unnecessary exposure of the child during operation. Children, with their small bulk and thin and vascular skin, part very rapidly with their animal heat, and exposure of the surface, especially if it be a wet surface, to the air often induces chill and increases shock. During operation every particle of surface not necessarily exposed should be kept dry and covered and extra warm.

CONCLUSIONS

These are but a few examples among many that could be cited, which show not only that it is easy to make mistakes in surgical practice, but that it is extremely easy to make them in the surgery of children; that many conditions may be present in the child which never or seldom occur in the adult; that it is a great mistake to suppose that surgical conditions in the child present the same phenomena, pursue the same course, are followed by the same results and can be handled in identically the same manner as conditions bearing the same name, but exhibited in the adult patient; that many mistakes are made which are entirely unnecessary and inexcusable and would not be made, if the profession possessed the proper knowledge of children and their surgical conditions.

1175 Wilson Avenue.

ABSTRACT OF DISCUSSION

DR. FRANK GENGEBACH, Denver: No doubt all of us could recite instances similar to those recited by Dr. Kelley. I wish to relate an instance in which several mistakes were made. About eight years ago, while I was on duty in the hospital a boy was sent in with a diagnosis of appendicitis. About all I could find was the symptom of pain referred to McBurney's point. After an examination of the chest I found increased cardiac dullness, but the heart sounds were clear. Posteriorly I heard bronchial breathing, and I made a tentative diagnosis of bronchopneumonia. He had irregular temperature, some cyanosis and some dyspnea. The next day the symptoms were, if anything, worse. The area of dullness still persisted and the breath sounds and heart sounds were still as clear as ever. I suggested the possibility of a purulent pericardial effusion. The next day the symptoms were so bad that we did a pericardial paracentesis and withdrew some pus. The surgeon was called in and he accepted my diagnosis as correct, and decided to resect some ribs and empty the pericardial sac. Just before the operation one of my confrères examined the boy and said my diagnosis was incorrect and that I had probably gotten into a sacculated pleuritic effusion. The chest was tapped in several places with negative results. Resection of the ribs was then performed and nearly a quart of pus evacuated. The patient did very nicely and I went off duty shortly afterward. A few days later I was asked to come at once, as the intern was unable to get the surgeon and the boy was in *extremis*. When I reached the hospital the boy was dead. We performed an autopsy and found nearly a quart of pus in the sac. The drainage tube had been taken out too soon, and a reaccumulation of pus had caused death.

DR. JOHN ZAHORSKY, St. Louis: I think the most common mistake I have seen is circumcising the young baby during the first few days of life because he does not pass any urine. Often they pass no urine because they do not get any fluid. Again, I have seen them circumcised on the eighth or tenth day in the presence of intense icterus. I think icterus is a contraindication. Another thing is the applying of strong antiseptics. A recent mistake I saw occurred in an infants' hospital in a case of septic urethritis. An x-ray was taken and it was thought to be a condition of the femur, but it was found to be septic urethritis. I had a case of acute scurvy treated as a case of inflammation of the hip-joint. There was no evidence of scurvy in any way, except that the child had

been taking food for months that frequently produces scurvy. In one case the physician was called to see a child that had stenosis of the larynx and he thought it was diphtheria. He injected four or five thousand units of antitoxin and sent for me to intubate. Just before I arrived the child coughed up a piece of peanut shell. The parents thought that this excellent result was due to the injection. We have often seen posterior laryngeal abscess diagnosed as diphtheria. One child had a stenosis of the nose and the surgeon thought it was laryngeal obstruction. In another case there was a large post-pharyngeal abscess and I was asked to intubate because it was thought to be a laryngeal stenosis.

DR. S. W. KELLEY, Cleveland, Ohio: My primary object in writing this paper was to draw attention to the fact that inasmuch as pediatrics has been cultivated more by physicians than by surgeons, it has come about that through ignorance of pediatrics by certain surgeons and ignorance of surgery by physicians many mistakes are made, and children suffer and sometimes die as a consequence.

RESULTS OF EXPERIENCE WITH NOGUCHI MODIFICATION OF THE WASSERMANN SERO-DIAGNOSIS TEST FOR SYPHILIS*

J. F. WAUGH, M.D.
CHICAGO

In selecting a method for the performance of the complement-fixation test of syphilitic sera, we were influenced by several factors, chief of which were the following:

In studying the different methods carefully and comparing the results obtained by different workers, we were impressed by the apparent accuracy of Noguchi's modification of the Wassermann test as shown by Noguchi¹, Fox², Swift³, and others.

It was also much more convenient to secure human than sheep's blood for immunizing our rabbits and for the corpuscle suspension used in the test.

This paper is not intended to criticize any one method or to compare the efficiency of the different methods; but to give the results and conclusions drawn from the examination of four hundred and ten sera by Noguchi's method.

The majority of the patients were private patients of Drs. Hyde and Ormsby. The control specimens of syphilitic blood were secured from patients in Cook County Hospital.

Technic of the Test.—The technic employed was practically that originally recommended by Noguchi and described by him. A few minor changes were made in the method of securing some of the materials necessary for the test, but these had no relation to, and changed in no respect, the method of procedure in the test.

Five factors are employed in the test: antigen, complement, amboceptor, patient's serum, and human corpuscles.

Antigen.—The antigen used in this series was very kindly furnished by Dr. William T. Mefford, of Chicago. It was an alcoholic extract of a syphilitic liver and prepared by him. It was standardized by us according to the outline given by Noguchi.

Preparation of the Complement.—In the majority of cases, old guinea-pigs give the most satisfactory complement. I have found the most convenient and efficient method of securing the blood to be as follows:

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Noguchi: Serum Diagnosis of Syphilis, 1st Edition, 1910

2. Fox: Jour. Cutan. Dis., xxvii, 338-357.

3. Swift: Arch. Int. Med., iv, pp. 376-404.

The pig is anesthetized, the plicordia shaved and sterilized and with a sterile syringe and needle sufficient blood for the test in hand is withdrawn from the heart. With a little practice and experience, difficulty is rarely encountered in piercing the heart with the needle. As much as 5 c.c. may be withdrawn from a good sized animal; from 5 to 10 c.c. N. NaCl are then injected into the peritoneal cavity in order that the vitality of the animal may remain at par. After the blood is withdrawn, it is permitted to clot at room temperature, the serum is removed with a pipette and placed in the ice box till ready for use. I never use a complement over thirty-six hours old.

The results in the earlier cases of this series clearly indicated that the sera of guinea-pigs varies greatly as to the amount of complement present. This undesirable feature was remedied in the following manner:

In securing the blood, as described, the life of the animal is spared and its health does not seem to be impaired. The serum from each animal is standardized according to Noguchi's directions as to the strength of the complement present; and after the first serum from each animal is tested, the additional labor of standardizing the complement every time a test is made, as suggested by Clark,⁴ is dispensed with. Furthermore, in private laboratories and in isolated districts where difficulty is encountered in securing guinea-pigs, it is very essential that the life of the animal be spared. Some of our guinea-pigs have been bled eight or ten times at intervals of three weeks, and the titer of the complement of each animal remains unchanged.

Preparation of Amboceptor.—A rabbit, preferably an old male, is immunized against human corpuscles as follows:

The blood from a normal individual is obtained by venipuncture from the arm, placed in sterile centrifuge tubes, de-fibrinated by stirring briskly with a piece of firm twisted wire. After being centrifuged the serum is removed with a pipette and the corpuscles washed with normal salt solution. After three washings, the supernatant NaCl solution being pipetted off each time, the suspension is made up with salt solution to the original amount of blood. It is then injected into the peritoneal cavity of a rabbit in increasing quantities and at intervals of five days, beginning with 3 c.c., then 6 c.c., 9 c.c., 12 c.c., 16 c.c., and lastly 20 c.c. Eight to ten days after the last injection, two or three c.c. of blood is withdrawn from the heart in the same way as when taken from the guinea pig, the animal being anesthetized. The serum is inactivated and tested as to its hemolytic properties as suggested and outlined by Noguchi. If the serum is found to contain an amboceptor of from .003 c.c. to .008 c.c. titer, 15 or 20 c.c. of blood are taken from the heart and immediately the same amount of salt solution is injected into the peritoneal cavity. At intervals of ten or twelve days, about 10 c.c. washed human corpuscles are injected into the rabbit. In this manner, an animal producing a good amboceptor can be kept indefinitely, and a fresh amboceptor of sufficient strength is always at hand.

Owing to the fact that so many rabbits after being injected are not satisfactory, it is very desirous that when we secure a good animal it be kept as long as possible. If after one series of injections the serum does not contain sufficient hemolytic properties, another series of injections may give a serum of the desired strength.

Blood to be Tested.—From 1.5 to 2 c.c. of the patient's blood is secured from the lobe of the ear, which has been properly cleansed. A puncture is made with a straight, three-cornered, sharp, surgeon's needle, which makes an opening sufficiently large so that the blood as a rule flows quite freely. It is collected in a glass tube that has been drawn out to a capillary point and bent in U-shape, the capillary arm being much the shorter. The small opening must be sufficiently large so that the lumen will not be occluded by the clotted blood before a sufficient quantity has been obtained. By making a good deep puncture, then gently squeezing the lobe, the drops are forced out; the capillary end of the tube is placed against the drop, which is drawn into the tube by capillary attraction. The tube should be held in the horizontal position. Difficulty is rarely experienced in getting sufficient blood in this way and it is usually less painful and disagreeable to the patient than when

taken from the finger or by venepuncture. The specimen of blood is kept at room temperature for three or four hours, during which time the clot forms and the serum separates. The latter is withdrawn by a pipette, the rubber bulb on the pipette being perforated in order to control the serum better, inactivated by heating to 56° C. for thirty minutes and then placed in the icebox. It is advisable to make the test as soon as possible after the blood is procured. However, when the serum is inactivated and kept in a cool place it may be kept for several days. A strongly positive syphilitic serum was kept in the icebox several months with no impairment of its strength.

Suspension of Normal Corpuscles.—Two graduated centrifuge tubes are desirable in preparing the suspension. Into these is put a definite amount of normal salt solution. Blood is secured from the finger, a tourniquet having been applied and then the puncture made. The blood is permitted to drop into the tubes of salt solution in the proportion of one drop to 4 c.c. salt solution. The number of specimens to be tested will determine the number of drops to be drawn. The corpuscles are washed twice, after which the proper suspension is made. Two tubes are required for each serum to be tested, 1 c.c. of the quarter drop suspension being placed in each. A fresh suspension will usually give better results than corpuscles kept in the icebox for one or more days. Hemolysis is more complete in the control tubes and the contrast in a very mildly positive case more pronounced.

After the material for the test is prepared an outline similar to that in Table 1 is used.

TABLE 1

	Tube number.	Inactivated serum, 18 c.c., 4 cap- illary drops.	Antigen, 1 unit.	Complement, 2 units.	Corpuscle suspen- sion, 1 c.c., ¼ drop.	Amboceptor, 2 units.	Result.
Patients' serum	1	+	+	+	+	+	?
	2	+	0	+	+	+	Hemolysis
Positive syphilitic serum	3	+	+	+	+	+	No hemolysis
	4	+	0	+	+	+	Hemolysis
Normal serum	5	+	+	+	+	+	Hemolysis
	6	+	0	+	+	+	Hemolysis
	7	+	+(2)	+	+	+	Hemolysis
	8	..	..	+	+	+	Hemolysis

The tubes are numbered and arranged in a suitable rack or holder. One unit antigen, two units complement (usually from .03 to .04 c.c.), .08 c.c. of the inactivated patient's serum or four capillary drops are placed in tube 1. The same, with the exception of the antigen, which is omitted, is placed in tube 2. In tube 3 is the same amount of antigen, complement and corpuscle suspension, but positive syphilitic serum is added in place of the serum to be tested. Tube 4 is the same as tube 3, except that antigen is again omitted. Tube 5 contains normal serum with antigen, complement, and corpuscles. The antigen is again omitted in tube 6, the other material being the same. Tube 7 contains two units antigen, complement and corpuscles. Double the amount of antigen is added to this tube to see if it will inhibit hemolysis. Tube 8 contains complement and corpuscles. The tubes are shaken up well, then incubated for one hour at 37° C. Two units of amboceptor are then added to each tube and all the tubes are again incubated at the same temperature. Progress in the process of hemolysis should be closely observed. When hemolysis is complete in the control tubes, 2, 4, 5, 6, 7, and 8, and if there is complete inhibition to hemolysis in tube 3, the result in tube 1 is noted.

In part of the cases of this series additional control tubes were used, in some of which the complement was omitted, and in others the amboceptor was not added. But when the controls, as used in above table, are satisfactory, they seem to be amply sufficient.

The sera from fifty-two patients representing thirty-two diseases other than syphilis gave the results shown in Table 2.

4. Clark: Jour. Infect. Dis., vii, p. 476.

The entire list was negative with the exception of one case of general paresis and seven cases of tabes which were positive; six cases of tabes being negative. There were also thirty cases of hypochondriacal syphilis and thirteen normal sera, all of which were negative.

In Table 3 are two hundred and ten cases in each of which is given the duration of infection, the type of lesion, if any was present, the treatment including both remote and recent, and the result of the test.

TABLE 2.—DISEASES OTHER THAN SYPHILIS

Disease.	Number of Cases.	Result.

† In this and following table — indicates a negative reaction; +, mildly positive; ++, strong; +++, very strong.

TABLE 4.—TREATED CONTINUOUSLY OR IRREGULARLY FROM THE TIME OF INFECTION

Duration of Infection.	Manifest Signs.					No Signs.					Total
	1-6 Mos.	6 Mos. 1 Yrs.	1-1½ Yrs.	1½-2 Yrs.	2-3 Yrs.	1-6 Mos.	6 Mos. 1 Year.	1-1½ Yrs.	1½-2 Yrs.	2-3 Yrs.	
.....	1	..	2	..	3	2	4	11	12	13	48
+	4	3	4	2	1	..	1	4	2	3	24
++	..	2	..	..	1	..	..	1	..	2	6
+++	1	..	1	..	1	..	..	1	1	..	5
Total.....	6	5	7	2	6	2	5	17	15	18	83

Manifest signs: Positive, 77 per cent.; negative, 23 per cent.
No signs: Positive, 26½ per cent.; negative, 73½ per cent.
Total: Positive, 42 per cent.; negative, 58 per cent.

In Table 4 there are eighty-three cases in which the duration of infection was from one month to three years, the patients having been treated continuously or irregularly for the same period of time. Of this number, twenty-six had manifest signs of the disease, 77 per cent. being positive and 23 per cent. negative.

Fifty-seven patients had no signs of syphilis, 42 per cent. of tests being positive and 58 per cent. negative.

In fifteen cases of the above number giving a negative result, treatment was continued till the day of the test. Later when mercury was discontinued for three or four weeks, a positive reaction was secured in those cases where a second test was made. So it is evident that mercury influences the result of the test in a great many cases. In order to eliminate this factor, treatment should be dispensed with for at least one month before the specimen of blood is taken for examination.

It is interesting to note that some cases of syphilis under vigorous mercurial treatment, regardless of the manner in which the metal is administered, will give a strongly positive reaction even when the treatment is continued till the day of the test; others will become negative with but little treatment. So the question of the virulence of the infection becomes a very important one. This not only depends on the activity of the infecting organism itself, but is also influenced by the resistance on the part of the individual. In all probability a patient under treatment, giving a positive test requires a longer period of treatment to effect a cure than one giving a negative result under similar conditions. In the former case, the patient may not be reacting well to treatment or the virulence of the infection may be greater.

TABLE 5.—TWO YEARS OR LESS TREATMENT. DURATION OF INFECTION 3-30 YEARS

Duration of Infection	Manifest Signs.				No Signs.				Total
	3-5 Yrs.	5-10 Yrs.	10-15 Yrs.	15-30 Yrs.	3-5 Yrs.	5-10 Yrs.	10-15 Yrs.	15-30 Yrs.	
.....	1	2	1	2	7	10	6	3	31
+	14	1	4	4	7	2	1	1	34
++	1	1	..	..	2	..	1	..	4
+++	1	..	..	..	1	..	..	1	3
Total.....	2	17	2	6	13	18	9	5	72

Manifest signs: Positive, 81½ per cent.; negative, 18½ per cent.
No signs: Positive, 42 per cent.; negative, 58 per cent.
Total: Positive, 57 per cent.; negative, 43 per cent.

Table 5 represents seventy-two cases of patients having had two years or less of remote treatment, the duration of the infection being from three to thirty years. Forty-five of this number were free from signs of syphilis, 58 per cent. being negative and 42 per cent. positive. The remaining twenty-seven cases had signs of the disease, 18½ per cent. being negative and 81½ per cent. positive.

TABLE 6.—TWO TO THREE YEARS' REMOTE TREATMENT. DURATION OF INFECTION 3-20 YEARS

Duration of Infection.	Manifest Signs.			No Signs.			Total
	3-5 Years.	5-10 Years.	10-20 Years.	3-5 Years.	5-10 Years.	10-20 Years.	
.....	1	1	..	4	7	1	14
+	..	..	3	2	1	2	8
++	..	..	..	..	..	..	..
+++	..	..	1	1	..	..	2
Total.....	1	1	4	7	8	3	24

Manifest signs: Positive, 66½ per cent.; negative, 33½ per cent.
No signs: Positive, 33½ per cent.; negative, 66½ per cent.
Total: Positive, 35½ per cent.; negative, 41½ per cent.

In Table 6, there are twenty-four cases of three to twenty years duration, and from two to three years remote treatment. Of these 58½ per cent. were negative and 41½ per cent. positive.

TABLE 7.—TREATMENT NOT KNOWN. DURATION OF INFECTION 3-30 YEARS

Duration of Infection.	Manifest Signs.					No Signs.					Total.
	3-5 Yrs.	5-10 Yrs.	10-15 Yrs.	15-20 Yrs.	20-30 Yrs.	3-5 Yrs.	5-10 Yrs.	10-15 Yrs.	15-20 Yrs.	20-30 Yrs.	
.....	..	4	..	..	2	..	3	9	4	3	25
+	..	5	2	7	..	..	..	2	1	1	18
++	..	..	1	..	1	1	..	2	..	..	6
+++	..	1	1	..	..	..	..	..	..	..	2
Total.....	..	10	5	7	3	1	3	13	5	4	51

Manifest signs: Positive, 76 per cent.; negative, 24 per cent.
No signs: Positive, 27 per cent.; negative, 73 per cent.
Total: Positive, 51 per cent.; negative, 49 per cent.

Table 7 represents fifty-one cases in which the duration of infection was from three to thirty years, the amount of treatment being unknown. In twenty-five of this number, signs of the disease being present, 76 per cent. were positive and 24 per cent. negative. Of the remaining twenty-six cases without signs, 27 per cent. were positive and 73 per cent. negative.

TABLE 8.—TREATMENT AND DURATION OF INFECTION UNKNOWN

	Manifest Signs.		No Signs.	Total.
	Early.	Late.		
.....	..	4	9	13
+	1	19	2	22
++	2	10	1	13
+++	..	12	..	12
Total.....	3	45	12	60

Manifest signs: Positive, 91½ per cent.; negative, 8½ per cent.
No signs: Positive, 25 per cent.; negative, 75 per cent.
Total: Positive, 78¾ per cent.; negative, 21¼ per cent.

In Table 8, there are sixty cases in which the duration of the infection and amount of treatment are not known. Forty-eight of these had manifest signs, 91½ per cent. being positive and 8½ per cent. negative. The remaining twelve patients were without symptoms of syphilis; 75 per cent. were negative and 25 per cent. positive.

TABLE 9.—NOT TREATED

Duration of Infection.	Manifest Signs.				Total.
	1-6 Months.	6 Mos.-1 Yr.	1-2 Years.	2-5 Years.	
.....	5	..	..	..	5
+	2	..	..	..	2
++	7	1	..	..	8
+++	17	1	3	..	21
Total.....	31	2	3	..	36

Positive, 86 per cent.; negative, 14 per cent.
Note.—In four of the five negative cases the exanthem had not appeared.

In Table 9, thirty-six patients with manifest signs and no treatment gave 86 per cent. positive and 14 per cent. negative reactions. Four of the five negative cases were in the chancre stage of the disease.

From a study of these cases we can readily see that in a large percentage of cases two or three years of treatment even when continuous is not sufficient to eradicate the disease. The patient may have had no signs of his trouble for many years and believe himself entirely cured, yet when the test is made, evidences of the old infection are shown when a positive reaction is secured.

In latent syphilis where the patient has been free from symptoms for a number of years and the disease again makes its presence known by signs or symptoms referable to the skin, the central nervous system, or some one of the viscera, the question at once arises, where has the hidden and concealed focus been located?

There seems to be no doubt that such a focus of infection may be present in a great many cases, and, being walled off by connective tissue in Nature's attempt to overcome the disease, may lie dormant for variable periods of time, until, owing to some unknown etiological factor, the spirochetes and their toxins are taken up by the blood and lymph and carried to all parts of the body. A positive serum test in such cases would be expected even if at some former date it had been negative, owing to the quiescent state of the concealed focus of infection. When these walled-off foci are on the surface of the body, it is not difficult to secure a few drops of serum from the lesion to be used in the test; at the same time serum from the patient's blood can be tested and the difference in strength of reaction noted. In Case 228 of this series, the serum from the blood was negative, while the serum from the lesion on the patient's arm, which had been present five years, gave a strongly positive reaction. In Case 404, both the serum from the blood and that from the lesion were strongly positive. More work along this line will be necessary before final conclusions can be drawn; but we are led to believe that in such cases a protecting wall of tissue is preventing the organism and their toxins from entering the general circulation in any appreciable amount. This condition would explain why we get so many negative reactions in cases where there are evidences of the disease, and positive results where no signs of syphilis can be found; the focus being concealed in some part of the body not accessible to touch or vision. If such a condition is possible, the difficulty in clearing up some of the latent lesions which do not react readily to vigorous specific treatment is more readily understood, as but little if any of the medicinal preparation penetrates the protecting wall of tissue. The palmar and plantar syphilides are striking examples of this class of cases.

CONCLUSIONS

1. In serum diagnosis of syphilis a positive result is an indication that the disease is still active and that more treatment is necessary.
 2. One negative result should not suffice in any suspected case of syphilis. The test should be repeated at intervals of six months for the first year after all treatment is discontinued and afterward at longer periods.
 3. In quite a large percentage of cases two years of specific treatment, regardless of the manner in which it is administered, is not sufficient to insure a negative result from the serum test.
 4. The tendency at the present time is rather to give insufficient treatment in syphilis than to over-treat the disease.
 5. The Wasserman test is of inestimable value in obscure cases of syphilis, and in differential diagnosis.

Origin of the Term "Stone Blind."—A correspondent writing to the *Lancet* of July 23 refers to the words "stone blind" as a popular term for complete and hopeless blindness. He states that he has been unable to trace its origin but imagines that it first came into use in the days before glaucoma was understood as a pathologic process. At that time, he says, it was common knowledge that an eye of "stony hardness" had no chance of sight, and he quotes Platner, who in 1745 spoke of the eye—"oculus qui caligat.....durusque fit." The explanation is plausible and interesting.

FROM THE STANDPOINT OF THE WAS-
SERMANN REACTION *

B. C. CORBUS, M.D.

Adjunct Professor of and Instructor in Genito-Urinary Diseases,
College of Physicians and Surgeons, Medical
Department, University of Illinois
CHICAGO

The years 1903, 1905 and 1907 each marks a definite step in the advancement of our knowledge of syphilis.

With Metchnikoff's and Roux's inoculation experiments on the higher apes in 1903 the scientific world again renewed its efforts to discover, if possible, the cause of syphilis, and when Schaudinn and Hoffmann announced the *Spirochæta pallida*, in 1905, the diagnosis of primary syphilitic lesions was placed on a definite basis.

The establishing of the *Spirochæta pallida* as the etiologic factor in syphilis has been fraught with much criticism, because the discovery did not conform to Koch's postulates. The work of Metchnikoff, Roux, Neisser and many others stands out in bold relief and has put the specificity of the *Spirochæta pallida* on so firm a basis that, notwithstanding their inability to culture the organism, it is now accepted by syphilographers the world over.

The complement-fixation test as discovered by Bordet and Gengou, and elaborated by Wassermann, Neisser and Bruck, has brought us in still closer relation with this universal disease. Like the *Spirochæta pallida*, it has had its full share of criticism and condemnation, a large part of which was due to imperfect technic and application. That it is absolutely specific and of immense clinical value is a conclusion that can be drawn from the many reports that have appeared in the literature and the thousands of cases that have been examined.

The Wassermann reaction is valuable for both the general practitioner and the specialist. Neisser¹ says that the Wassermann reaction reveals syphilis with such certainty that nothing would induce him to dispense with it now.

Positive findings are a distinct indication of existing syphilis, and repeated negative findings are extremely valuable for a favorable prognosis, although the test is not infallible in every case. It is as important for the general practitioner as is the microscope for the determination of gonorrheal secretions. The Wassermann test is most valuable for the syphilographer, not only as an aid in the diagnosis but also in the treatment of syphilis. Until the discovery of the *Spirochæta pallida* and the application of the Wassermann test little indeed was known about this universal disease, save what could be seen externally and on the mucous surfaces. With the introduction of these two means of diagnosis we have at last something tangible to work with. It is possible now to make an exact diagnosis and to begin treatment at once, telling the patient with some degree of assurance what his future may be.

Hönc² analyzes the findings in 1,512 cases of certain and of suspected syphilis and in 320 non-syphilitic

patients. The findings confirm the specific importance of the test and show that energetic mercurial treatment is able to transform a positive into a negative reaction in a large proportion of cases.

A positive reaction was obtained in 23 out of 107 prostitutes with apparently no signs or history of syphilis.

Boas³ has applied the Wassermann test in 1,345 cases. He states that positive findings after systematic treatment of syphilis are invariably the precursors of a recurrence. The serum test applied once a month in the first years after infection, and the resumption of treatment in case of positive findings, will certainly have a marked influence in warding off recurring trouble.

Purkhaner⁴ reports from Neisser's clinic the findings of the Wassermann test as applied to 5,200 cases of syphilis. The findings were positive in inverse proportion to the number of intermittent courses of treatment that had been applied in the individual cases. The more energetic the treatment, the smaller the proportion of positive reactions. A single course of treatment does not seem to have much effect on the outcome of the test, but the general impression is all in favor of a thorough treatment in the first months and years after the infection.

W. Scholtz⁵ says that the Wassermann reaction is generally negative from the third to the sixth week after infection, and as a consequence it is only of slight value for early diagnosis.

Therapeutically the Wassermann test is of importance because it indicates that it is possible in a degree to cure syphilis by abortion, but the proof cannot be substantiated without further observation, extending over years.

Jesonek and Merowsky⁶ say that we should bend every effort to change a positive to a negative reaction, because every syphilitic with a positive reaction is in danger of tabes and paralysis.

The earlier the treatment commences and the more energetically it is carried out the sooner will a positive reaction become negative. Chronic intermittent treatment unquestionably gives the best results, but we cannot as yet say whether this can make a negative reaction permanent.

It is true that these discoveries may dull the diagnostic shrewdness of the clinician and in time lessen his ability, but, like all biologic tests, they should be used as adjuncts, not as first aids, in diagnosis.

I have been working two years with the Wassermann reaction in practice. I began with the original Wassermann technic and have adhered to it throughout the whole time.

In reporting these cases, care has been taken to note carefully the results in making the Wassermann test. Alcoholic extract of a liver of a congenital syphilitic was used as an antigen, with plenty of known normal and syphilitic serums as controls, and each tube was tested twice with different strength antigens, each acting as a control for the other.

For convenience I have adopted the following classification:

Group I. New cases treated after the biologic method.

A. Chancre, before the Wassermann reaction was positive.

B. Early secondaries, after the Wassermann was positive.

DR. M. L. HEIDINGSFELD, Cincinnati: There is one phase of the Wassermann test to which I wish to direct special attention. Cases of syphilis, after treatment has been instituted, frequently develop a negative Wassermann, sometimes after very little treatment. On the other hand, other cases, in spite of very vigorous treatment, will show a decidedly positive reaction for a long period. This is probably due to the fact that the Wassermann test is a test of "antibodies," or the reaction of the system against syphilis, and not of the virus itself. In two cases of malignant syphilis on my service at the Cincinnati Hospital, in which both patients developed early rupia, and the malignant nature of the disease was well defined in all its aspects, the Wassermann reaction was negative from the very beginning, and in spite of the most energetic mercurial and arsenical treatment, it never gave a single positive reaction after repeated tests. One of the patients died eighteen months after infection; the other is still alive, but is in desperate straits. These patients have never reacted against the disease; probably no antibodies were formed, and the Wassermann test was therefore negative.

DR. J. A. FORDYCE, New York: I have watched the results of the Wassermann reaction during the past two years in my private and public practice, and these observations have led me to the belief that it is a method of great diagnostic importance. Regarding its practical or therapeutic application, it seems to emphasize the fact that mercury given hypodermically or by inunction has a greater influence over the reaction than mercury given internally. Furthermore, the earlier the treatment of the disease is begun the sooner the reaction becomes negative. It may be stated conservatively. I think, that the treatment of syphilis as generally carried out is very inefficient; that mercury is given in too small doses and that the use of potassium iodid is only exceptionally indicated in the secondary stage of the disease, though frequently it is relied on by practitioners from the beginning.

DR. WILLIAM LITTEBER, Nashville, Tenn.: I have made Wassermann tests, using different antigens, in twenty cases of pellagra. Three out of the twenty reacted positively. In one out of the three positive cases there was a history of syphilis; in another, an indefinite history of lues. I do not believe that the Wassermann reaction will be positive in non-syphilitic cases of pellagra; and this is in accordance with the experience of Dr. Howard Fox, although Bass has reported positive reactions in practically every case examined by him. In our cases we employed both the original Wassermann and the Noguchi tests, and both gave uniformly negative results.

I have found that in some cases, the use of the protoiodid of mercury internally does not obliterate the Wassermann test, but when we change to the inunction method, it usually becomes negative in a fairly short time. In some cases, the inunction method seems to be more efficacious than the injection method, and *vice versa*. We cannot be absolutely positive which is the better method, but I agree with Dr. Fordyce that either is preferable to the internal method.

DR. WILLIAM T. CORLETT, Cleveland: I think we are generally agreed as to the value of the Wassermann reaction in syphilis. A year ago I spent some weeks in the laboratory of Professor Finkler at Bonn, working up the Wassermann reaction. The difficulties in carrying out the reaction in private practice are great, and I think it should be largely left to men doing laboratory work. This applies not only to the technic, but to the skill and experience necessary to read the reactions aright. There is another point I wish to refer to, and that is the influence the Wassermann reaction may have on our therapeutic methods in the treatment of syphilis. For a number of years, my observations have taught me that cases of syphilis treated with any form of iodine during the early stage of the disease run a more protracted course and prove more obstinate to treatment than do cases in which iodine has been withheld. Further, I have long been convinced that mercury is the only drug that has any definite and constant influence in eliminating the syphilitic virus. Both observations have been verified by the Wassermann reaction.

DR. ALFRED SCHALEK, Omaha: I wish to report a case that came under my observation lately. The case was one of syphilis, pursuing a very malignant course, but under persistent

treatment with inunctions and injections the symptoms finally cleared up. The patient subsequently went to Europe where he saw Prof. Neisser, who had a Wassermann test made, which proved negative. A similar test was afterward made by Dr. Schamberg of Philadelphia and was again negative. Shortly after that the patient developed symptoms pointing to a syphilitic brain lesion, and he is in a hopeless condition today. Our indications are clear when the Wassermann test is positive, but how do we stand as to the continuation of treatment when it is negative?

DR. E. H. MARTIN, Hot Springs, Ark.: I was very much interested in the statement made by one of the speakers that the spirochetes might remain sealed up in the connective tissue for a number of years, and that under those conditions, mercury was not effective. I was also interested in the statement made by Dr. Corlett that mercury was the only drug that was effective in controlling this disease during its early stages. That I believe is a mistake. We have in the arylarsonates a powerful remedy for the treatment of early syphilis. I have used the various preparations of the arylarsonates in about 200 cases of syphilis, and while I am not prepared to say that with them I am satisfied to get along without mercury in the treatment of this disease, yet I have found them very effective. Under the use of these remedies the lesions cleared up in at least one-third of the time that they would with the iodids, and in one-tenth of the time that they would with mercury alone. Arsenic, we know, has the power to penetrate the tissues, and hence may destroy spirochetes sealed up against mercury. In the case reported by one of the speakers here today, where the Wassermann test gave a negative reaction in the face of marked pernicious syphilis, I can almost promise him that the symptoms in such a case will respond to the arylarsonates.

DR. ALFRED SCHALEK, Omaha: In the case I reported, the symptoms failed to yield to any of the preparations of arsenic.

DR. EDWARD BOWE, Jacksonville, Ill.: I am more particularly interested in this subject from the standpoint of mental and nervous diseases, as I have seen a number of cases of tertiary brain lesions. Presuming, as a neurologist, that one is called on to make the differential diagnosis between a specific lesion of the brain and a brain tumor, one can readily appreciate the importance of having such a test as the Wassermann reaction to fall back on. In many such cases we get a very obscure history of syphilis, or none at all. Given a history of syphilis, the treatment may have been inadequate or inefficient, and under such conditions you can readily see the value of such a diagnostic test as this. If the reaction was positive, it would give us a direct indication as to treatment and aid us in the prognosis. The same applies in dealing with obscure cord lesions.

DR. OLIVER S. ORMSBY, Chicago: In our office it has now become a routine measure to examine all doubtful cases of syphilis by the serodiagnosis test. In cases in which syphilis is shown to exist, the treatment should be continued as long as the test is positive. Some authorities say that a patient with syphilis should be treated as long as he lives; others differ from this view. It is evident that in some individuals syphilis persists for many years, while others recover promptly. The results of the Wassermann test confirm this. Some cases show a negative reaction after a few months, while others persist in giving a positive reaction in spite of long-continued treatment: the latter are usually of the virulent type. As an example the following case is cited: A patient developed a profuse exanthem of the florid type; this disappeared under energetic treatment, mercury being given by injection, inunction and internally at different times during two years of constant treatment. Three months after he was discharged his blood was tested and gave a positive Wassermann reaction. At the time the patient was apparently healthy and had exhibited no symptoms of syphilis since the first outbreak two years previously. Before we had time to institute further treatment, he developed paralysis of the third nerve, and since then he has had almost uncontrollable symptoms. The Wassermann test is a most valuable addition as an aid in diagnosis and should always be considered in conjunction with our knowledge of the clinical manifestations of syphilis.

Dr. V. J. COHENOUR, Joliet, Ill.: In reply to Dr. Bowe I would say that a patient may have a non-syphilitic brain tumor and still have syphilis, and in such a case the Wassermann reaction would not throw much light on the differential diagnosis. If the case is one of brain syphilis without a brain tumor, the chances are that the symptoms will clear up under anti-syphilitic treatment, whereas in brain tumor you would get at best but a temporary remission of the symptoms. The fact I wish to bring out is that we may have a combination of these two conditions. I have seen individuals with chronic syphilis in whom the Wassermann test gave a negative reaction at one time, and a strongly positive reaction perhaps six months later. In some cases of gumma, for instance, where a negative reaction is obtained, the administration of potassium iodid for some time may be followed by a positive Wassermann, indicating that the drug has stirred up some of the syphilitic products. As to the curability of syphilis, I think that when once a man has syphilis, he always has syphilis. I have examined men who were treated in the ordinary way for ten or fifteen years, and thoroughly treated, and still, in spite of that, they showed decided symptoms of the disease later on. I have found that by the inunction method of treatment the reaction is decidedly quicker than by any other. Next to this, I favor the injection method, and lastly, internal treatment. The test I prefer is the unmodified Wassermann, and I do not find it particularly difficult.

Dr. J. F. WATGII, Chicago: My experience with this test in the field of nervous diseases has been rather limited. In the series of cases reported, there were thirteen cases of tabes, seven being positive and six negative; and two cases of general paresis, both positive. In cases of suspected syphilitic involvement of the central nervous system, the test is of the greatest value. However, a negative result does not preclude the possibility of syphilis, as the results of practically all investigators in latent syphilis will prove. Judging from the effect of treatment in converting a positive into a negative result in a given case, it would seem that the most efficient manner of administering mercury is by injection or inunction. Even after a negative result is secured and the patient is apparently free from his disease, the test should be repeated at intervals for a number of years. In this manner it is quite probable that many of the late manifestations of the disease can be prevented. Future work along this line will undoubtedly disclose interesting facts.

Dr. B. C. COMBES, Chicago: In order to get accurate results from these tests we must of course have a good laboratory, and the technic must be faithfully carried out. When the result is positive, it demands early and energetic treatment.

THE TREATMENT OF STAMMERING *

G. HUDSON MAKUEN, M.D.

Professor of Defects in Speech at the Philadelphia Polyclinic Hospital and College for Graduates in Medicine; Laryngologist and Otologist to the Chester Hospital, Chester, Pa.; Consulting Laryngologist and Otologist to the Douglass Memorial and the Roosevelt Hospitals, Philadelphia

PHILADELPHIA

CLASSIFICATION

In any consideration of the treatment of stammering, it is convenient and desirable to make three classes. In the first class we put all those nervous children who present any abnormalities of speech development; in the second class, those who have begun to show a tendency to stammer by an occasional hesitancy of speech, and in the third class, the confirmed stammerers, those who not only stammer but who know that they stammer, and whose natures have been deeply influenced by it. There are three stages of the affection, therefore, the prodromal, the acute, and the chronic. The first

stage is generally characterized by the psycho-physical condition called nervousness, and the speech is rapid and blustering. The second stage is like the first, but it presents the added phenomena of speech hesitation and a more or less frequent repetition of certain sounds. The third stage may represent all the characteristics of the first two, but in a more pronounced form, and it presents in addition all those phenomena both mental and physical which together constitute what may be called the stammering habit.

First Stage.—What shall we do for the nervous child who inherits, it may be, a tendency toward stammering, whose ideas are confused, whose speech is rapid and blustering and whose environment is such as to aggravate all these unfortunate conditions? The remedy is not far to seek, but we must admit that it is not always so easy of application. The time to cure stammering is before it begins. Children should never be allowed to stammer, and the so-called habit never should be formed.

Speech is an acquired faculty and stammering is an acquired defect. To save the child from the second and third stages it is manifest that he must be taken out of his unfavorable environment; he must not be allowed to hear rapid and blustering speech, which, by the way, is common in families of which stammerers are the offspring, and by no means must he be allowed to hear others stammer, because of his natural and almost perverse inclination to imitate anything which is unusual and undesirable. By the same reasoning he must have good examples of speech, he must be taught to do things quietly and in order, to think of only one thing at a time, and to speak with deliberation. Don't scold the child because he is already in an excited condition and scolding will merely add fuel to the flame. Don't make fun of him or call his attention to his defect, for this will embarrass him and lead to a nervous dread of future trouble. Always keep in mind the fact that the child is striving to combine the art of ideation with that of oral expression. It is all new to him. His thoughts come rapidly and the words with which he attempts to clothe them tumble out spasmodically, somewhat as water comes out of a bottle. He tries to say everything at once. He cannot arrange his thoughts in order and he has difficulty in selecting suitable words for their expression. The vocal and articulating organs share in the general confusion and they soon begin to lose their normal automatic action. It is at this point that careful treatment will almost surely prevent a further development of the trouble.

The treatment should begin at the kindergarten age, and it could be given in the kindergarten school by especially trained teachers, but the work would be greatly hampered, if not altogether negatived, by the home environment of such children, in which confusion and excitement usually reign supreme. The ideal place, therefore, for such a patient would be in a special hospital school, away from his mother and father, and brothers and sisters, who together, unwittingly of course, are oftentimes directly responsible for his condition, and who if given a little time and opportunity, will surely lead the unfortunate one into the second stage.

The Second Stage.—I have described the second stage as that of speech hesitation and frequent repetitions of sounds. The treatment of this stage should be similar to that of the first, but some additional measures must now be adopted. In the first place the patient must be speedily cured in order to save him from the mental complications attendant on the third stage of the affec-

* Read before Chicago Medical Society April 6, 1910.

tion. It is cruel to send such a child to school, and as a rule he should be taken out of his home and kept in the atmosphere of good speech. He should be drilled in the elements of speech, and given respiratory, phonatory and articulatory exercises. The child should be trained in the natural easy use of the speech mechanisms, and this should all be done without any reference being made to his tendency to stammer. Indeed it is quite possible to cure him of the affection at this stage without his really knowing that he had it.

Third Stage.—Coming now to the third stage of stammering. It is in this stage that we find the affection in its fullest development and with all its psychological variations. The ultimate cause, whatever it was, may have long since disappeared, but the disastrous results are plainly manifest in the character and disposition of the afflicted one. Mentally, physically, and sometimes also morally, there seems to be no health in him, and I know of no disease which so taxes the skill and ingenuity of the physician as does this combination of nervous derangements.

ESSENTIALS OF CURE

The stammerer himself is of the opinion that he is organically and radically different from other people, and he is skeptical as to the outcome of any line of treatment or practice. If you, perchance, succeed in removing his skepticism, he even then has scarcely enough will power or energy to pursue any course of treatment which may be prescribed for him. His great desire oftentimes is to be cured quickly and without any effort on his own part. To whom shall such a one turn for relief? "Certainly not," as Alexander Graham Bell says, "to any pretender who veils his method in convenient secrecy, nor to any who profess to 'charm' away the impediment—or to effect a cure in a single lesson! Not to any whose 'system' involves drawing, sniffing, whistling, stamping, beating time—all of which expedients have constituted the 'curative' means of various charlatans; nor to any who bridle the mouth with mechanical appliances—forks on the tongue, tubes between the lips, bands over the larynx, pebbles in the mouth, etc., etc. The habit of stammering can only be counteracted by the cultivation of a habit of correct speaking founded on the application of natural principles."

I quote further from Dr. Bell because his thought on the subject concurs so thoroughly with my own: "But with the best assistance the stammerer must work out his own cure. He cannot be passive in the matter. He must clearly apprehend the principles on which he is to proceed and diligently apply them. Nor must he in this depend too much on the watchfulness of his instructor, but must learn to watch over himself. His perfect release from the habit will require time, patience, and hopeful, energetic effort."

How shall we assist the stammerer to work out this cure? That is the problem. We are somewhat in the position of a watchmaker who is handed a chronometer that will not keep time. It is not enough for him to say that the steel is not properly tempered and that the springs are not properly annealed, but he must make the watch go. So it is not enough for us to say that the stammerer has inherited or acquired certain disabilities, but we must show him how to overcome them or to supplant them with desirable mental and physical characteristics.

If he has weak will power, we must show him how to strengthen it. If he lacks the faculty of attention or concentration, we must show him how to acquire it. If

he has grown morbidly introspective and self-conscious, he must be shown how to overcome this condition. If he is suffering from fixed ideas and obsessions, if he has become neurasthenic or psychasthenic, as many of them have, he must be cured of these diseases before he can possibly be cured of his speech malady. In other words, he must learn to control himself before he can hope to control his speech.

SPECIFIC METHOD

As to specific methods, I should say that it is not so much the method as its application that is of value. Of course, there are methods good and bad, and there are methods which are better than others, but the best methods are those the application of which will result in the development of the proper mental attitude on the part of the patient, and incidentally in the highest efficiency of voice and speech. Mental culture, voice culture and speech culture must form the basis of every rational method of treatment. The stammerer should acquire a high degree of vocal power and the greatest possible articulatory skill and efficiency. These he can get, of course, only with the assistance of an experienced teacher. He thus learns to play on his own instrument as the pianist learns to play on the piano, all the time acquiring skill and proficiency by well directed and persistent practice.

Now what are the special exercises that have been found to be the most suitable for this purpose? I shall have time only to refer to them and their application. In a general way, the stammerer should learn the "physiologic alphabet" theoretically as well as practically. He should learn exactly how to produce and articulate, if you please, every one of the elementary sounds of speech and he should learn to hear them accurately and know when he himself produces them accurately. In other words, he must develop his ear for speech before he can make any progress in speech culture.

He must also learn the exact musculature of speech, and when an untoward action or coordination appears in any of the three peripheral mechanisms, it should be pointed out to him, and suitable exercises given to correct it. In this way the patient gradually learns how to regulate his nervous energy, how to inhibit certain hitherto overacting nerve impulses which have resulted in the muscle spasms characteristic of stammering, and how to distribute the innervations to the various mechanisms in their proper order and intensity.

One difficulty with the stammerer is that he tries to speak entirely with the articulatory mechanism, apparently ignorant of the fact that the effort should be chiefly directed to the vocal mechanism. His attitude in this respect towards singing is more nearly what it should be. In singing he directs his attention to the vocal mechanism and therefore he rarely stammers.

Having learned the physiologic alphabet, or table of sounds, we have found it good practice to drill the patient in phonetic reading, and what Dr. Bell has called syllabication. Normal speech, of course, is largely automatic and independent of any conscious interference. Moreover, it is acquired originally by imitation and without any conscious effort. Hence it is that when the child stammers he knows neither why he does it nor how to stop it. He may be helped to stop it, as I have said, during the first and even during the second stage without his ever having known that he did it, but in the third stage it is generally necessary to have him thoroughly reorganize his methods of speech, to have him bring all the processes well within the domain of his consciousness and to teach him to control them entirely

by volitional effort. This reorganized or relearned speech must then be practiced until great facility has been acquired in the new physiologic use of all the muscles, respiratory, phonatory, and articulatory, and this should be done in precisely the same way and for much the same reason that the student of the piano practices finger exercises.

Indeed the stammerer should be taught to regard his organs of speech as an instrument apart from himself, on which he must learn to play just as the pianist learns to play on the piano. This facility of speech is absolutely essential to the stammerer. He must know that he can control his speech; not only so but he must know that he knows that he can do it, in order that in the future he may be able to overcome the distracting influences of the fear of stammering which always lurks in the mind long after the cure has been accomplished. The stammerer himself is oftentimes the last one to be convinced that he is cured, and hence it is that we have here a field for the practice of psychical as well as physical therapeutics.

STAMMERERS AND THOSE WHO STAMMER

Finally, as someone has said, there are those who stammer and those who are stammerers, meaning, I suppose, that we all stammer to some extent, but the stammerers are those who are conscious of their difficulties and whose cerebral activities are disturbed by them. Those who stammer are the ones described as being in the first and second stages of the affection, and the stammerers belong to the third or chronic stage.

Those who stammer may be unconsciously relieved of their difficulties by simple elocutionary measures, consisting of training in respiration, phonation and articulation, while the stammerers must reorganize their speech by means of the same elocutionary measures, plus training in mentalization. I always ask my assistants to train the patients in these four things, respiration, phonation, articulation and mentalization, entirely regardless of the fact that they are stammerers, and I tell them that the object of the training should not be primarily to cure stammering but rather to develop good voice, facility of articulation and the right mental attitude, and when this is done all other desirable things will be added thereto.

The stammerer naturally cares little for voice and speech culture, but his chief desire, as I have said, is to get rid of his difficulties and the shorter the cut to this goal the better it suits him. His mental attitude in this respect must be changed. He must become interested in speech culture for its own sake if he would be safely and permanently cured. It is this faulty mental attitude that explains why stammerers are attracted to the various "get cured quick" schemes such as are in vogue, of course, for purely mercenary ends.

PROGNOSIS

I am often asked how long it takes to cure stammering, and in answering this question I am reminded of the following little incident: An old book gilder was asked how long it would take to learn his art and he said, "Some learn it in five years and some never learn it." I do not wish to leave you with the impression that there are some people who never can be cured of stammering, but I mean to say that there are people so organized constitutionally that the acquirement of any degree of facility of speech is an exceedingly laborious task, and for them to overcome a defect like stammering requires long and persistent practice of physio-

logic methods. The prognosis, however, is always good when the patient can be induced to do the things that are essential to the reorganization of his speech, and there can be no more healthful physical exercise or efficient mental discipline than that which comes with the study and practice of speech culture.

1627 Walnut Street.

A CASE OF OPIUM-POISONING

E. B. CLAYBROOK, M.D.
CUMBERLAND, MD.

The following case is reported, because the man was in such profound stupor, and seemingly in such a dangerous condition, and yet responded so promptly to the treatment instituted, as to give no trouble or uneasiness to those in attendance.

History.—J. W. S. was admitted to Alleghany Hospital on June 30, 1910, with no history except that he was taken from a train on the way from a near-by town, in profound coma. There happened to be in the hospital a patient from the same town, who knew the man, and said that he was a painter subject to painter's colic and a hard drinker.

Examination.—The man was in profound coma, pupils pinpoint, pulse soft and regular, respiration three to the minute, temperature normal, urine normal. The diagnosis of opium-poisoning was made.

Treatment and Result.—The stomach was washed out, and the bladder emptied. Supra-orbital pressure and castigation with a wet towel brought no response whatever. The left median cephalic vein was opened for saline transfusion and five pints of saline solution in which $7\frac{1}{2}$ grains of caffeine citrate had previously been dissolved, were allowed to flow in rapidly through an eye-dropper. The man made no response to any attempts to arouse him, or to the incision and the handling of the wound, but began to writhe as the stitches were put in; and by the time the wound was sutured, sat up in bed and talked rather clearly. His respiration complete and he gave no further trouble. It was afterwards found on questioning him that his home doctor gave him a "good strong" hypodermic before he left home and some powders of morphin with directions as to taking them. As the pain was not relieved in a few minutes from the hypodermic he then "took all the powders at once" and boarded the train.

61 Washington Street.

NOTES ON CERTAIN TESTS FOR INDICAN IN THE URINE

H. I. DAVENPORT, A.M., M.D.
AUBURN, NEW YORK

The following notes are published as a caution to those who make routine examinations of the urine for indican. It is sometimes necessary to preserve the urine for a time before the test can be made, and for this purpose formaldehyd solution should not be used; at least not when bleaching powder or potassium permanganate is employed as the oxidizing reagent. I have been unable to find note of this in the texts at my command (Emerson, Wood, Simon), nor have I seen attention called to the fact in any published article. Emerson says, however, "A person must be wary in a chemical examination of such a urine" (i. e., one preserved with formaldehyd solutions).

The tests used are the ordinary ones, as follows: Ten c.c. of concentrated hydrochloric acid is poured into a test-tube containing a like amount of the urine to be tested. This is mixed and potassium permanganate and

chloroform added alternately drop by drop, agitating, until about 2 c.c. of chloroform and a sufficient quantity of the permanganate have been added. The other test is the Jaffe test. Ten c.c. of concentrated hydrochloric acid are placed in a test-tube and a very small drop of fresh concentrated solution of ordinary bleaching-powder is placed on the lip of the tube. The hydrochloric acid is poured into a tube containing 10 c.c. of the urine, carrying with it the drop of bleaching-powder solution. Two c.c. of chloroform are then added. In either of the tests after the addition of the chloroform the tubes are slowly inverted and the chloroform takes up the indican, the result being a bluish color of the chloroform layer.

CASE 1.—An acid urine containing a rather large amount of indican (both tests) was divided into two portions and the one left unpreserved, the other preserved with formaldehyd solution (one drop of the 40 per cent. solution to 4 fl. oz. of urine).

In testing these specimens on the following day it was found that the unpreserved urine gave the indican test as on the previous day while the one containing the formaldehyd did not show the slightest color in the chloroform layer. Both tests were employed with the same result. The urines were acid.

CASE 2.—This patient was taking potassium iodid and the chloroform layer showed the purple color due to the mixture of the pink color of the iodine and the blue of the indican. The urine was divided into two portions as before. The indican tests had shown a very large amount present. To one portion was added formaldehyd solution as before; the other was left unpreserved. The next day the unpreserved portion gave both tests as before, while the one containing the formaldehyd solution showed the pink color due to the iodine and a very slight trace of the blue. These two specimens were again set aside and tested on the tenth day. At this time the unpreserved urine gave no trace of indican with either test and the preserved urine showed only the pink color of the iodine. The urine remained acid in all cases.

CASE 3.—This patient was suffering from acute pulmonary tubercle, phlogia and the urine was loaded with indican (first test only). The specimen which was acid was divided into three portions; one was left unpreserved, one was preserved with formaldehyd solution as above; the third was preserved with chloroform in the proportion of one part of chloroform to twenty-five parts of urine. The one to which the formaldehyd solution was added was tested immediately with a negative result (both tests). On the tenth day all were tested; the unpreserved urine was alkaline but showed indican in almost the same amount as at first; the specimen preserved with formaldehyd solution showed no indican, the specimen preserved with chloroform was acid and showed as much indican as the original. (Both tests were used on all specimens).

CASE 4.—Acid urine with a fairly large amount of indican. This was divided into two portions and one left unpreserved. After eight days the specimen preserved with chloroform showed indican, but the result in the unpreserved specimen was doubtful. Both were acid and were acid on the fifteenth day when tests showed indican present in the one preserved with chloroform but absent from the unpreserved specimen. (First test only).

CASE 5.—Acid urine with considerable indican, divided into three portions and formaldehyd solution added to each in the proportion of 1 to 800, 1 to 150, 1 to 75, respectively, as nearly as could be approximated. Tested at once, the first specimen showed some indican but not nearly so much as the untreated urine; the second specimen was doubtful; the third (i. e. 1 to 75) was negative.

CASE 6.—Acid urine with small amount of indican. Formaldehyd solution added to three portions in the proportion of 1 to 1,700, 1 to 700, and 1 to 500, respectively, as nearly as could be approximated. Tested after five days, the first specimen showed some indican, the second result was doubt-

ful, the third specimen negative. After ten days the same specimens showed, the first positive, the second and third negative. (The first test only was used).

In all forty-eight cases were tested, but the results were in no case at variance with the following conclusions, and only selected cases are mentioned above.

CONCLUSIONS

1. Formaldehyd added to urine as a preservative interferes with the tests for indican above described (Cases 1, 2, 3, 5 and 6).
2. This interference seems to be in proportion to the amounts of formaldehyd solution and indican present (Cases 5 and 6).
3. Formaldehyd does not seem to interfere with these tests for the presence of iodine (Case 2).
4. Chloroform as a preservative does not seem to interfere with these tests for indican (Cases 3 and 4).
5. The urine should be examined fresh, if possible, as the indican may disappear from an unpreserved urine on standing (Cases 4 and 2).

The following case is also of interest in this connection:

A patient showing much indican in the morning specimen on each of two successive days was given, on the second day, ten grains of hexamethylenamin in two-grain doses two hours apart. The morning specimen on the third day showed no indican by either of the above tests. No more of the drug was given, and on the fourth day the morning specimen showed considerable indican while on the fifth and sixth days the amount of indican was about as on the first two days. The source, or rather cause, of the indicanuria in this patient could not be determined.

We must conclude from this case that if the patient is receiving hexamethylenamin these tests for indican may fail to show any present, and this failure is probably due to the influence of the formaldehyd contained in the drug.

SUCCUSSION SPLASH IN DIVERTICULUM OF THE ESOPHAGUS

C. M. COOPER, M.B., CH.B. (EDIN.)
SAN FRANCISCO

In a recent paper I referred to the presence of a succussion murmur in one patient with a pharyngo-esophageal diverticulum. The finding of this splash in three other patients similarly affected would seem to indicate that this sign is of distinct value in the clinical investigation of patients. As the real condition in all four of these cases had escaped recognition, a description of this maneuver may be of value.

The patient is asked to drink as much water as he conveniently can, preferably at a time when the sac is most likely to be empty, i. e., the early morning. Then the patient's larynx is grasped by the hand and the soft tissues of the neck vigorously shaken. During this time the patient is requested not to breathe or swallow. The examiner, with the ear near the patient's neck, can readily hear the splash of the fluid in the sac. The dry creak or rattle heard and felt while shaking the larynx of thin or aged people must be differentiated from the splash.

IMPROVISATION OF A ROLLER BANDAGE
FROM A SQUARE OR HANDKER-
CHIEF BANDAGE

W. H. BAILEY, M.D.

Assistant Surgeon to Out-patient Department of Rosedale Hospital,
KANSAS CITY, MO.

In emergency cases in which a dressing or a splint is required it sometimes happens that a square or handkerchief bandage does not serve the purpose nearly as well as a roller bandage. The method here described

Fig. 1. Method of tearing cloth so as to improvise a roller bandage from a square of cloth.

is one by which a roller bandage may be made from a handkerchief very quickly and easily. It might seem that the improvised bandage would be too clumsy and weak; but if it is applied firmly and neatly it will be

Fig. 2. Method of folding strips of cloth before being rolled.

found to hold quite as snugly as a regular roller bandage.

The cloth is first torn or cut as shown by the heavy lines in Figure 1. The first strip is then folded directly

backward or downward, as far as to the point *a* (Fig. 1) where it is joined to the second strip, as shown at *a* (Fig. 2); now the first strip (1) is folded on its longitudinal axis along the line *b* (Fig. 1), so that the first and second strips are in the same straight line as at *b* (Fig. 2). This process is repeated for all the strips, the folding taking place at alternate ends of the square. It makes no particular difference which way each strip is folded to bring it into line with the next one.

The bandage is then rolled and applied like any roller bandage. The strength and neatness of the bandage can be added to a little if it is pinned, before being rolled, at the places where the folds occur; but it works very satisfactorily without this added precaution.

This method can be used with a piece of cloth of any length or width. The bandage, of course, can be improvised out of other shapes than the square. Also the width of the completed roller can be made anything that is desired simply by varying the width of the original strips cut or torn in the square used.

PARTIAL GANGRENE OF THE LEFT INDEX-
FINGERCAUSED BY THE SYMBIOSIS OF THE FUSIFORM BACILLUS
AND THE SPIROCHLETA DENTICOLAJ. F. HULTGEN, M.D.
CHICAGO

L. E., aged 7, was brought to consultation by her relatives August 6, 1910, on account an ill-smelling but fairly painless affection of her left hand, which had existed for a week but had become worse the last two days. On examination I found the nail of the left index-finger hanging to its bed by only a few shreds, covering a necrotic area which was surrounded by discolored, pultaceous, and extremely fetid tissue-remnants. The upper half of the distal phalanx of the left index-finger was destroyed, but the splacelus was limited at the distal phalangeal joint by slightly irritated, reddish, and moderately swollen tissues. There was similar, but only slight, perionyxis of the left thumb; no systemic disturbance, slight left axillary adenitis; several carious teeth; gums not very healthy; throat negative. The patient was well developed, and evidently in good health.

Microscopically, smears from the affected finger-tips showed a pure culture of the peculiar, symbiosis of two germs, the *Bacillus fusiformis* of H. Vincent (1896) and the *Spirocheta denticola* of W. D. Miller (1892). Preparations from the carious teeth showed the same organisms. The girl is in the habit of biting her fingers, and the etiologic connection between her teeth and the gangrenous affection of the left finger nail-beds is quite plain.

This is, I believe, the first case on record of a gangrenous perionychia due to this symbiosis. It must be remembered that these parasites are also the specific pathogenic agents of the following affections: ulcers-membranous angina (Plaut and Vincent), ulcerative stomatitis (Bergerson, Bernheim and Poposil), pyorrhea alveolaris or Rigg's disease, of many cases of noma, of hospital gangrene (Vincent), of tropical phagedenic ulcer (Vincent), of balano-posthitis (Bataille and Berdal) the so-called "fourth venereal disease" of F. G. Harris and B. C. Corbus. These germs live as facultative saprophytes in the mouth of normal individuals, and thence are inoculated into various parts of the body, internally as well as externally, attaining there pathogenic virulence under conditions as yet unknown to us.

Therapeutics

HEMORRHAGE FROM GASTRIC ULCER

Before instituting treatment for this very disturbing condition the physician should remember that statistics show that fatal hemorrhage from ulcer of the stomach is rare, probably not far from 1 per cent. of patients with this trouble dying during hemorrhage. Frequent occurrence of hemorrhages, of course, will soon cause anemia and perhaps lead to very serious loss of nutrition. Long before this condition occurs a surgical cure should have been instituted.

The object of this editorial is to call attention to a discussion of the subject by Dr. J. Kaufmann, of New York (*American Journal of the Medical Sciences*, June, 1910). He very sensibly states, in the first place, that gastric hemorrhage from this cause is rarely fatal; in the next place that an operation performed while the hemorrhage is going on would be extremely unsatisfactory: Either it is not necessary and the hemorrhage has ceased, or the patient is so exsanguinated as to make an anesthetic of any kind unjustifiable, and in the third place, it is difficult at the best, and more especially when there is blood in the stomach, to determine where the ulcer is located. The bleeding stops naturally from two causes; either from vaso-constriction of the bleeding vessel or vessels, or from the formation of a thrombus at the mouth of the bleeding vessel. Anything, then, that would increase the power and force of the general circulation as cardiac tonics, saline transfusions and circulatory stimulants would seem to be, and generally is, contraindicated. It has been repeatedly urged in article after article that cardiac tonics and vasoconstrictors are not indicated when the bleeding point cannot be reached and the hemorrhage locally stopped. In other words, when there is internal hemorrhage, whether somewhere in the abdomen, in the lungs, or in the brain, anything like digitalis or ergot is contraindicated, and when the bleeding stops after such medication it is a matter of sequence and not on account of the drug action. It is perfectly true that venous oozing and venous hemorrhage, sometimes bleeding from the nostrils, bloody expectoration from the lungs, when an insufficient heart is the cause, may be very well stopped by a cardiac tonic like digitalis, but generally when we discuss hemorrhage we mean arterial hemorrhage or an actual erosion of a vessel.

Therefore, anything that depresses the circulation unless the bleeding is sufficient to cause lowered arterial pressure and actual syncope, would be of advantage. It would be a brave man who would do venesection to stop a gastric hemorrhage, but as a matter of fact such treatment would often save the patient blood.

Kaufmann states that he has seen Esmarch bandages placed on the limbs, thus removing this blood from the body circulation, aid in causing the cessation of the hemorrhage.

As to local treatment aimed at stopping the hemorrhage, we can but agree with Kaufmann when he states that styptics and most local hemostatics such as acetate of lead, perchlorid of iron, oil of turpentine, and even tannic acid are as likely to cause nausea and vomiting as to stop the hemorrhage. As above stated, ergot should not be given at all, either by the stomach or hypodermatically. The vasoconstriction which adrenalin locally causes is followed by a reaction dilatation. This Kauf-

mann thinks may eventually cause a renewal of the hemorrhage. However, by the time of the vasodilatation a thrombus may have become firmly fixed in the bleeding vessel. Gelatin given by the mouth or in any other way is unsatisfactory. Calcium chlorid can do good only after absorption by rendering the blood a little more coagulable, hence it is a useful medicament only in repeated hemorrhages.

Kaufmann speaks of the serum treatment of hemophilia. We cannot see how this can be of any value in perforation of a vessel in the stomach, unless the patient is a hemophilic.

He finds the most satisfactory method of treating gastric hemorrhage is at first to do gentle gastric lavage. He has done this gastric washing so many times with satisfaction that he is not afraid of causing more hemorrhage. He does not believe it can ever cause perforation, unless the stomach is over-distended by very large quantities of water. In fact, if perforation was about to take place, he is not sure but that gastric lavage might save the patient's life by cleaning the stomach before the perforation. In other words, an ulcer that was not ready to perforate would not be perforated by lavage. If in his opinion the hemorrhage had ceased he would not do lavage, but if there was more or less constant bleeding he would do it, and the removal of a possibly insufficient thrombus from the bleeding part would only enhance a better contraction of the blood vessels and prevent a second or repeated serious hemorrhages.

The tube is inserted, (the patient lying down) and pushed just far enough to secure siphonage. The quantity of water used at a washing should be about 300 c.c. This cleansing of the stomach from what may have been there before the hemorrhage and from digesting and decomposing blood is of marked advantage in preventing vomiting and distress and causing the stomach to be at complete rest. In fact, these masses of clotting, disintegrating blood may cause gas and stomach distention and really actually cause another hemorrhage. Kaufmann also finds that a bleeding stomach may suddenly become dilated which would leave blood and perhaps food in the pendent portion, and this alone should be another cause for lavage.

Certainly after the lavage, and often before if it seems that the hemorrhage is about to stop, large doses of "crystalline bismuth subnitrate" should be administered. The crystalline form supposedly sticks more pertinaciously to the surface of the ulcer and allows the blood to agglutinate to the bismuth mass. Bismuth is not sufficiently astringent to contract the blood vessels to stop hemorrhage, but does aid in the coagulation of the blood and at the same time is soothing to the stomach, the exact opposite of the more active astringents.

For the subsequent treatment of gastric ulcer see *THE JOURNAL* of July 16, 1910, page 219.

It is interesting to note that Kaufmann believes that, paradoxical as it may sound, ulcers that have some time or other caused profuse hemorrhage are those that are the most readily cured.

APPENDICOSTOMY

This surgical procedure in order to better medicate the colon has passed the stage of experiment and is a resource for cure that must be considered in protracted colitis. The development of the various specialities has given increased importance to local treatment. It is

of course true that so-called general or constitutional treatment stands in little danger of being entirely abandoned at any early date. It is also unquestionably true that some specialists in their enthusiasm over operative and local treatment have many times neglected general treatment to the disadvantage of their patients. But one who concentrates his study on a particular part or organ of the body naturally becomes more and more eager to get directly at the seat of the trouble, to examine it with direct vision, to manipulate it with the fingers, and to apply remedies directly to the lesion or to treat it instrumentally or operatively.

The small intestine and the colon long resisted such direct attacks for diagnosis and treatment. Colonic irrigation is a not very ancient attempt to apply local treatment to the large intestine, while exploratory laparotomy greatly broadened our opportunities for diagnostic investigation of the small intestine.

Mayo Robson, in 1893, reported a case of colitis in which a cure had been effected by means of an artificial anus in the colon.

In 1898, Dr. Francis W. Murray, of New York, treated a case of amebic dysentery of two years standing by performing a right inguinal colostomy and subsequently irrigating the colon with antiseptic solutions. The patient left the hospital before he was entirely cured, but was seen six months after, when his condition was found to be very satisfactory. He had gained in weight, was able to resume his work as a tailor, and had an average of two or three movements a day, generally formed, sometimes loose, and generally containing mucus.

By this operation two important indications of treatment were met. First, securing complete rest of the affected part by diverting the feces from the colon, and second, irrigations of the colon with solutions of quinin or nitrate of silver.

Further observation demonstrated that the latter indication was the more important and that the former might be disregarded.

Bolton, in 1901, proposed to make an artificial anus in the cecum with a finger-like projection of the tissue into the lumen of the cecum which should act like a valve and prevent the escape of the intestinal contents.

In 1902, Dr. Robert F. Weir, of New York, having commenced to do Bolton's operation in a case of ulcerative colitis, saw the appendix appear in the wound and decided to utilize it in making the desired fistula, which he did by suturing the appendix in the wound, removing its tip, and through its lumen injecting a solution of nitrate of silver.

Since then this operation has been done by many surgeons in the treatment of a variety of conditions affecting the intestines.

Dr. W. B. Russ, of San Antonio, Texas, has recently published (*Texas State Journal of Medicine*, August, 1909) a comprehensive review of this subject, describing the evolution and the various modifications of the operations and enumerating the various diseases and conditions in which it has proved useful.

The disease in which appendicostomy has its field of greatest usefulness is amebic dysentery. J. M. Holt, of the Public Health and Marine-Hospital Service, has expressed the opinion that this disease is much more common in the United States than has been commonly supposed, and that microscopic examination of the

stools will often demonstrate that a "case of intractable diarrhea" is really amebic dysentery. These cases often resist indefinitely all forms of medical treatment.

At first advised only in chronic cases, some surgeons now advise operation in acute cases which do not soon yield to medical treatment. Many remarkable results following operation have been reported by surgeons of widely separated localities. Various solutions have been used for irrigating the bowel. Some excellent results have been reported from simple water; commencing with water at the temperature of the body and using water of lower temperature at each irrigation until ice cold water is used.

Most surgeons have used solutions of quinin 1 to 5,000 to 1 to 2,000, or of nitrate of silver 1 to 1,000 to 1 to 250. The fistula should not be allowed to close until there is no question of the complete recovery of the patient.

In mucous colitis irrigations with nitrate of silver solutions have proved very beneficial. In tubercular and syphilitic ulceration of the colon, irrigations with nitrate of silver solutions and ichthyol solutions, in connection with appropriate general treatment, have caused great improvement and in some instances have effected a cure. Gant, of New York, after a large experience says, "I have no more hesitation in advising appendicostomy and cecostomy for the relief of chronic diarrhea than I have for recommending appendectomy for appendicitis."

Appendicostomy with irrigation has also been recommended in septic peritonitis, in connection with drainage through tubes passed deeply into Douglas' cul-de-sac; in pernicious anemia in which it assists in removing from or diminishing the number of the anaerobic bacteria in the colon; in chronic constipation with headache, insomnia, and mental depression; and in the ileocolitis of children, which is not promptly controlled by dietetic and medicinal treatment.

It is becoming realized of late that in some instances of gastrointestinal irritation in which the symptoms have been attributed to appendicitis, and an appendectomy has been performed, the operation has not effected a cure, but the symptoms have persisted. In such cases there is considerable reason to believe that appendicostomy with irrigation of the colon will relieve the symptoms much more completely than the removal of the appendix and the closure of the abdomen.

Other conditions in which this operation has already proved, or seems likely to prove, beneficial are ileocecal intussusception, volvulus in which the cecum is involved, autointoxication, enteric or typhoid fever; also to prevent gaseous distention of the ileum, and to relieve dangerous post-operative conditions, in which irrigation through the appendix with warm saline solution will prevent or relieve shock, avoid distention, and assist elimination.

In some cases where irrigation of the ileum as well as of the colon is desirable cecostomy may be preferable to appendicostomy.

In rare instances this up and down or proximal and distal irrigation has been accomplished by means of an appendicoenterostomy, the tip of the appendix being opened and fastened into the ileum at its lower extremity. The loop of the appendix being brought into the abdominal wound, and after it had become united to the surrounding tissues being opened, irrigation may be readily performed in both directions.

HEMORRHAGE FROM GASTRIC ULCER

Before instituting treatment for this very disturbing condition the physician should remember that statistics show that fatal hemorrhage from ulcer of the stomach is rare, probably not far from 1 per cent. of patients with this trouble dying during hemorrhage. Frequent occurrence of hemorrhages, of course, will soon cause anemia and perhaps lead to very serious loss of nutrition. Long before this condition occurs a surgical cure should have been instituted.

The object of this editorial is to call attention to a discussion of the subject by Dr. J. Kaufmann, of New York (*American Journal of the Medical Sciences*, June, 1910). He very sensibly states, in the first place, that gastric hemorrhage from this cause is rarely fatal; in the next place that an operation performed while the hemorrhage is going on would be extremely unsatisfactory: Either it is not necessary and the hemorrhage has ceased, or the patient is so exsanguinated as to make an anesthetic of any kind unjustifiable, and in the third place, it is difficult at the best, and more especially when there is blood in the stomach, to determine where the ulcer is located. The bleeding stops naturally from two causes; either from vaso-constriction of the bleeding vessel or vessels, or from the formation of a thrombus at the mouth of the bleeding vessel. Anything, then, that would increase the power and force of the general circulation as cardiac tonics, saline transfusions and circulatory stimulants would seem to be, and generally is, contraindicated. It has been repeatedly urged in article after article that cardiac tonics and vasoconstrictors are not indicated when the bleeding point cannot be reached and the hemorrhage locally stopped. In other words, when there is internal hemorrhage, whether somewhere in the abdominal cavity or elsewhere, nothing but the results of the unrestricted use of fireworks. This was

one year after year, nevertheless each year the resort to lawlessness continued and the maiming, the killing, the burning to death of little children and the torturing by lockjaw went merrily on. Besides stating the awful toll of life and limb from this annual carousal, *THE JOURNAL* also pointed out that the responsibility clearly rested with city governments. As the constant dropping of water wears away stone, so this annual presentation of the facts began to have an effect. At first a few public-spirited newspapers—notably the *Chicago Tribune*, which had made a news feature of the list of accidents even before *THE JOURNAL* began the collection of more complete data—published the facts, then newspapers generally took up the cry and finally numerous magazines and periodicals, so that the demands for restriction of the sale and use of fireworks became too insistent to be disregarded. Several cities like Toledo, Chicago, New York and Boston employed restrictive measures whereby the casualties were greatly reduced, while other cities like Baltimore, Washington, Cleveland and Trenton passed prohibitory ordinances with the result that deaths and injuries were entirely prevented or were reduced almost to the minimum.

mann thinks may eventually cause a renewal of the hemorrhage. However, by the time of the vasodilatation a thrombus may have become firmly fixed in the bleeding vessel. Gelatin given by the mouth or in any other way is unsatisfactory. Calcium chlorid can do good only after absorption by rendering the blood a little more coagulable, hence it is a useful medicament only in repeated hemorrhages.

Kaufmann speaks of the serum treatment of hemophilia. We cannot see how this can be of any value in perforation of a vessel in the stomach, unless the patient is a hemophilic.

He finds the most satisfactory method of treating gastric hemorrhage is at first to do gentle gastric lavage. He has done this gastric washing so many times with satisfaction that he is not afraid of causing more hemorrhage. He does not believe it can ever cause perforation, unless the stomach is over-distended by very large quantities of water. In fact, if perforation was about to take place, he is not sure but that gastric lavage might save the patient's life by cleaning the stomach before the perforation. In other words, an ulcer that was not ready to perforate would not be perforated by lavage. If in his opinion the hemorrhage had ceased he would not do lavage, but if there was more or less constant bleeding he would do it, and the removal of a possibly insufficient thrombus from the bleeding part would only enhance a better contraction of the blood vessels and prevent a second or repeated serious hemorrhages.

The tube is inserted, (the patient lying down) and pushed just far enough to secure siphonage. The quantity of water used at a washing should be about 300 c.c. This cleansing of the stomach from what may have been there before the hemorrhage and from digesting and decomposing blood is of marked advantage in preventing vomiting and distress and causing the stomach to be at complete rest. In fact, these masses of clotting, disintegrating blood may cause gas and stomach distention will not easily pass. Kaufmann, in its achievements and in its hemorrhage, this is still more important—a commemoration which will create a stronger love for law, order and civilization. And when could such ideals be better set forth than in the celebration of July Fourth? Every paper we pick up and every popular magazine have articles nowadays showing that low morals, disregard for law, and graft, in high places and low, are rife enough without giving over our national holiday to further this decadence in our national life.

The commemoration of the Fourth of July is the nation's greatest opportunity for preaching the gospel of national and civic righteousness and for pointing the attention of hundreds of thousands of children to the characters which have made and developed this nation.

To *THE JOURNAL* it seems as though this is but the beginning of a mighty movement, not only to do away with the wanton destruction of life and limb by the use of fireworks, but to make of our national holiday a day of national upbuilding, a day for calling attention to the important incidents in American history; in fact, a day for the development of a genuine patriotism.

of course true that so-called general or constitutional treatment stands in little danger of being entirely abandoned at any early date. It is also unquestionably true that some specialists in their enthusiasm over operative and local treatment have many times neglected general treatment to the disadvantage of their patients. But one who concentrates his study on a particular part or organ of the body naturally becomes more and more eager to get directly at the seat of the trouble, to examine it with direct vision, to manipulate it with the fingers, and to apply remedies directly to the lesion or to treat it instrumentally or operatively.

The small intestine and the colon long resisted such direct attacks for diagnosis and treatment. Colonic irrigation is a not very ancient attempt to apply local treatment to the large intestine, while exploratory laparotomy greatly broadened our opportunities for diagnostic investigation of the small intestine.

Mayo Robson, in 1893, reported a case of colitis in which a cure had been effected by means of an artificial anus in the colon.

In 1898, Dr. Francis W. Murray, of New York, treated a case of amebic dysentery of two years standing by performing a right inguinal colostomy and subsequently irrigating the colon with antiseptic solutions. The patient left the hospital before he was entirely cured, but was seen six months after, when his condition was found to be very satisfactory. By this operation two important indications of treatment were met. First, securing complete rest of the affected part by diverting the feces from the colon, and second, irrigations of the colon with solutions of quinin or nitrate of silver.

Further observation demonstrates that in the outer dication of the vagina, and thus prevents the escape of deposited semen. The gland has been found in rats, guinea-pigs, mice and probably in hedgehogs, but not in human beings, rabbits and bullocks. It is further thought not to be present in the *Carnivora*, most of which have no seminal vesicles. In human beings the existence of the gland is suggested by the presence of coagulated particles in the semen and it may be the purpose of such coagula to prevent escape of spermatozoa from the vagina when the female is in the upright position.

stools will often demonstrate that a "case of intractable diarrhea" is really amebic dysentery. These cases often resist indefinitely all forms of medical treatment.

At first advised only in chronic cases, some surgeons now advise operation in acute cases which do not soon yield to medical treatment. Many remarkable results following operation have been reported by surgeons of widely separated localities. Various solutions have been used for irrigating the bowel. Some excellent results have been reported from simple water; commencing with water at the temperature of the body and using water of lower temperature at each irrigation until ice cold water is used.

Most surgeons have used solutions of quinin 1 to 5,000 to 1 to 2,000, or of nitrate of silver 1 to 1,000 to 1 to 250. The fistula should not be allowed to close until there is no question of the complete recovery of the patient.

In mucous colitis irrigations with nitrate of silver solutions have proved very beneficial. In tubercular and syphilitic ulceration of the colon, irrigations with nitrate of silver solutions and ichthyol solutions, in connection with appropriate general treatment, have caused great improvement and in some instances have effected a cure. Gant, of New York, after a large experience says, "I have no more hesitation in advising appendicostomy and cecostomy for the relief of chronic diarrhea than I have for recommending appendectomy for appendicitis."

Appendicostomy with irrigation has also been recommended in septic peritonitis, in connection with drainage through tubes passed deeply into Douglas' cul-de-sac; in pernicious anemia in which it assists in removing from or diminishing the number of the anaerobic bacteria in the colon; in chronic constipation with headache, insomnia, and mental depression; and in the ileocolitis of children, which is not confidently controlled by Anderson says that the only reason for not using such serums would be that a larger amount would have to be used to allow for the decrease in potency; but that old serums, unit for unit, are just as potent as fresh serums and would be perhaps less apt to cause severe reactions than fresh serums. He found that when diphtheria antitoxin was dried and kept in the dark at 40 F. it retained its potency practically unimpaired for five and one-half years. He suggests that such a dried antitoxin might be of value for use on long voyages and in the tropics.

INFLUENCE OF AGE AND TEMPERATURE ON THE POTENCY OF DIPHTHERIA ANTITOXIN

Many physicians, having occasion to use diphtheria antitoxin, have found that the return date on the package to be used had been reached or passed. This raised a doubt in their minds as to whether they should use this or obtain a newer package. Until recently there was little information on the question of the influence of age and temperature on the potency of diphtheria antitoxin and considering the importance of the subject it is surprising how little attention it has

Current Comment

POLIOMYELITIS

Reports indicate that poliomyelitis or infantile paralysis is quite prevalent in an epidemic form in many parts of the country. In some cases the true nature of the disease does not seem to have been appreciated until a considerable number of cases had occurred. This fact emphasizes the importance of physicians being on the lookout for the earlier cases, so that the disease can be controlled before it becomes epidemic. The conception

1. Anderson, John F.: The Influence of Age and Temperature on the Potency of Antidiphtheric Serum and Antitoxin Globulin Jour. Infect. Dis., 1910, vii, 481.

of the disease has somewhat widened in consequence of recent investigations and experience. That it has the nature of a general infection is evident from the manner of onset in many instances. Symptoms referable to the general system or to the digestive tract are apt to precede those which indicate the seat of the principal lesions in the nervous system. The early symptoms may also indicate involvement of the cerebrum so that the incautious practitioner may be led to conclude that he is dealing with an acute local disease of the brain. The general character of the early symptoms and the known prevalence of the disease should lead the physician to suspect the occurrence of poliomyelitis in cases presenting obscure indications of general infection with involvement of the nervous system. While the mode of transmission is not yet worked out it is evident that the disease is contagious, although there seems to be marked differences in susceptibility. The isolation of actual or even suspected cases is therefore important. Such isolation should be especially strict as regards young children. Unfortunately no curative or immunizing serum has yet been perfected, but with the activity of present bacteriologic research we may hope for an improved method of diagnosis and a specific treatment in the near future.

CHOLERA AND SUPERSTITION

Reports from southern Russia indicate that cholera is especially prevalent, while in St. Petersburg, with 1,000 cases in the hospitals, the number is increasing daily. The Russian authorities are said to be unable to suppress the spread of the disease and, too often with fatalism, regard it as unavoidable. The educated classes are inert and indifferent, while the peasants are fiercely opposing the sanitary authorities in their efforts to prevent the spread of the disease, attributing it, as usual, to the officials and the doctors who are trying to suppress it. Bulletins issued by the Russian government August 19 show a total to date of 112,985 cases, with a death roll of 50,287. As these figures show only the reported cases and deaths, it is probable that the actual numbers are even greater. Ignorance, superstition and fanatical opposition to progress still go hand in hand with filth, preventable diseases and an unnecessarily high death rate.

ABOLISH THE BLANK CARTRIDGE PISTOL

Blank cartridge wounds in eight years have caused 860 cases of tetanus, or 81.5 per cent. of all tetanus cases from Fourth of July injuries. Furthermore blank cartridge wounds cause more deaths in the annual celebration of our Independence Day than all other factors combined. In eight years, 854 deaths have been caused by this one factor! Most of the victims were bright, active boys from 6 to 18 years of age, who were doomed to die the most awful death known to medical science—a death the agony of which is probably not paralleled even by the tortures of the Inquisition. If this annual sacrifice were really necessary, it would be far more merciful to pick out the hundred or more youths each year and deliberately shoot them. But this an

outrage is not necessary; it is entirely preventable, and the prevention rests with the authorities of cities, towns and villages. For eight years THE JOURNAL has heralded these facts to the world; they have been given even wider publicity by some of our public-spirited newspapers and periodicals, and now no one can plead ignorance of the awful facts. Nevertheless, the governing bodies of the majority of our cities still view with the blind eye of callous indifference the fatalities for which they are morally responsible. Some cities have, indeed, passed prohibitory ordinances, but have not enforced them vigorously. To permit the use of blank cartridges and blank cartridge pistols at any time is little less than criminal.

WILLIAM JAMES

The death of Prof. William James, the eminent psychologist and writer, removes a distinguished member of the medical profession, though the fact that he was a member of our profession may not be generally known. Dr. James graduated from Harvard Medical School in 1869 and from 1872 to 1880 he taught in that school, first anatomy and later physiology. It was but a short step from physiology to philosophy, which he commenced to teach in 1880; and a still shorter one to psychology, of which he became professor in 1889. He is best known as a psychologist, both in this country and abroad. He would have been prominent in his original profession, but his work in mental science has so put in the shade his earlier record that it has been almost forgotten that he was a physician and a medical teacher. There is hardly any modern philosopher who is more often quoted in medical works, more especially those treating of mental affections and the mental treatment of disease. By his death our country has lost one of its most brilliant and lucid thinkers and broadest-minded philosophic investigators. Incidentally, as an instance of heredity of talent, it is worth mentioning that he was a son of a talented clergyman, and his brother, Henry James, Jr., is the well-known psychologic novelist whose name is familiar to lovers of literature wherever the English language is spoken.

DOLLARS VERSUS LIVES

The recent hearing at Washington in the Indiana benzoate of soda case places the manufacturers involved in a somewhat equivocal position through the emphatic replies of Dr. Wiley to some of the questions put to him. In the course of the cross-examination, according to the press despatches, the following statements were made:

"These tests are immensely important to the business world and involve thousands of dollars in property and products," said the attorney for the manufacturers.

"I don't care a hang for the business world," Dr. Wiley replied, promptly, "what I care for is the health of the people."

"You consider that more important than the interests of those who have hundreds of thousands of dollars tied up in property and products?" asked the attorney.

"I most certainly do," replied Dr. Wiley, "where there are thousands of dollars involved, there are millions of lives hanging in the balance which these investigations affect. It is these which I consider and not the business which may be done by any corporation."

Friends of the national Food and Drugs Act and advocates of its proper enforcement are certainly under obligations to the attorneys for the manufacturers for giving Dr. Wiley an opportunity to make such a straightforward statement of his position. *THE JOURNAL* and the medical profession have insisted from the beginning that the campaign was one of dollars versus lives. It was not to be expected, however, that the issue would be so clearly defined by the manufacturers themselves.

VITAL STATISTICS A BUSINESS ASSET

The Mississippi Land Development Association desires to attract immigration to that state. In preparing literature, the committee wished to make positive statements concerning the comparative healthfulness of the state. When the association attempted to secure reliable data on this point, however, it was found that no records of any sort existed by which the mortality or morbidity of the state could be ascertained. This proved such a serious drawback that business men interested in real estate and land development have taken up the question as a business proposition and are inaugurating a movement for the passage of a vital statistics law in order that official records of the state's healthfulness may be obtained. This action in a southern state is particularly gratifying, as that section has for many years been without adequate vital statistics. Only by carefully compiled official records is it possible to overcome the popular impression, which was created by serious epidemics in past years, of the comparative unhealthfulness of that portion of the country. It is therefore important that southern states adopt and enforce adequate vital statistic laws in order that the mortality and morbidity of the population may be a matter of record and not of rumor or surmise. Increasing healthfulness consequent on the suppression of malaria, yellow fever and hookworm disease, will be one of the best business assets for the new south.

HOGS SAVED FROM CHOLERA; NO HELP FOR BABIES

Two items recently appeared in a southern newspaper which apparently have no relation and yet are extremely suggestive. Here is the first one:

HOG-CHOLERA ERADICATED.—A report comes from Jackson that hog-cholera has been entirely eradicated from the state. Only one case was reported, it is said, that one being near Natchez. The usual serum was prepared and administered with excellent effect, so that there is said to be not a single case in Mississippi at the present time. The live-stock commission furnishes the serum for hog-cholera free of charge to veterinarians, and in the event of any outbreak, it can be quickly administered and the disease immediately suppressed.

The second was not considered of sufficient importance to call for a heading:

Without warning, little John McCabe, ten years old, son of Mrs. Elizabeth McCabe, was stricken by the hand of death this morning, and forty-five minutes later was no more. Death was due to spinal meningitis.

Careful examination of previous and subsequent issues of the newspaper fails to show that the state which furnished serum for hog-cholera made any effort to

secure a serum to save the life of little John McCabe, or to prevent the development of more cases of meningitis. A single case of hog-cholera is reported at once and the state live-stock commission takes immediate action. Yet no one knows how many children in Mississippi are suffering from spinal meningitis or even how many have died from that dread disease in the last year. The state which demands a report of every case of hog-cholera does not even record the death of a child from spinal meningitis or from any other cause. Another strange feature—no one objects to the state suppressing hog-cholera. In fact, the hogs of Mississippi have not even organized a National League of Medical Freedom.

FLORENCE NIGHTINGALE—HER WORK IS HER MONUMENT

The other day, Florence Nightingale was laid to rest in a quiet country churchyard in Hampshire. But for her known opposition to notoriety, the popular demand for her interment in Westminster Abbey would doubtless have been carried out. It was the personal request of the "Angel of the Crimea" that the strictest privacy should mark her funeral. It is proposed to erect a tablet in Westminster Abbey, as well as a public monument in London in memory of the woman who lessened the horrors of military hospitals and helped to ameliorate so far as possible the barbarities of war. This is right. But no monument can be erected that will adequately commemorate the services of this remarkable woman.

EIGHTH ANNUAL SUMMARY OF FOURTH OF JULY INJURIES

For the eighth consecutive year we are presenting statistics of injuries received during the celebration of the Fourth of July, with particular reference to tetanus resulting from these injuries. Every possible effort has been made to secure reliable data and all serious cases have been carefully investigated, so that, so far as the figures go, dependence may be placed on them. Lists of the patients treated at a large number of hospitals have been sent in and thousands of letters have been received from physicians in all parts of the country. In this way many cases have been reported which otherwise could not have been included in the statistics. Doubtless many injuries occurred which were not reported, but these must have been of very minor character. Thanks are extended to the health officers, the hospital superintendents, the physicians and others for the careful reports which have made these statistics practically complete and the figures reliable. The data are presented in the same manner as heretofore so that comparisons with the figures of previous years may be made.

FEWER CASES OF TETANUS

There were 72 cases of tetanus this year, the lowest number reported during the eight years *THE JOURNAL* has been gathering these statistics and less than half the number of last year, when 150 cases were reported.

of the disease has somewhat widened in consequence of recent investigations and experience. That it has the nature of a general infection is evident from the manner of onset in many instances. Symptoms referable to the general system or to the digestive tract are apt to precede those which indicate the seat of the principal lesions in the nervous system. The early symptoms may also indicate involvement of the cerebrum so that the incautious practitioner may be led to conclude that he is dealing with an acute local disease of the brain. The general character of the early symptoms and the known prevalence of the disease should lead the physician to suspect the occurrence of poliomyelitis in cases presenting obscure indications of general infection with involvement of the nervous system. While the mode of transmission is not yet worked out it is evident that the disease is contagious, although there seems to be marked differences in susceptibility. The isolation of actual or even suspected cases is therefore important. Such isolation should be especially strict as regards young children. Unfortunately no curative or immunizing serum has yet been perfected, but with the activity of present bacteriologic research we may hope for an improved method of diagnosis and a specific treatment in the near future.

CHOLERA AND SUPERSTITION

Reports from southern Russia indicate that cholera is especially prevalent, while in St. Petersburg, with 1,000 cases in the hospitals, the number is increasing daily. The Russian authorities are said to be unable to suppress the spread of the disease and, too often with fatalism, regard it as unavoidable. The same is true in this one case (occurring in Ogden, Utah), antitoxin was not given until the fourth day because no supply had been provided by the city and the physician was unable to secure it before that time. The value of tetanus antitoxin as a prophylactic appears so positive that very few cases have ever been reported in which active symptoms began after its administration. The list of tetanus cases is given in Table 1.

Tetanus occurred in 18 states, 7 less than last year and 2 less than 1908. Heretofore for five years Illinois has had the largest number, having had 20 cases last year, but this year that state reports 10 cases, falling below Michigan and Pennsylvania, each of which had 11. New Jersey had only 9 cases this year as compared with 19 last year, and Ohio reports only 4 cases this year, whereas there were 12 last year. Table 2 allows comparison of the number of cases in each state for the eight years.

Blank cartridges continue to be responsible for the great majority of tetanus cases, 64, or 88.9 per cent., this year being due to that cause as compared with 86.5 per cent. last year, 73.3 per cent. in 1908, 71 per cent. in 1907 and 60 per cent. in 1906. With the full knowledge of the awfulness of the deaths caused by blank cartridge wounds it is certainly inexcusable that the use of these instruments of torture is not absolutely prohibited. Five cases of tetanus this year were from gunshot wounds, 2 were due to injuries by fire-crackers and 1 was caused by a dynamite cap. None

outrage is not necessary; it is entirely preventable, and the prevention rests with the authorities of cities, towns and villages. For eight years THE JOURNAL has heralded these facts to the world; they have been given even wider publicity by some of our public-spirited newspapers and periodicals, and now no one can plead ignorance of the awful facts. Nevertheless, the governing bodies of the majority of our cities still view with the blind eye of callous indifference the fatalities for which they are morally responsible. Some cities have, indeed, passed prohibitory ordinances, but have not enforced them vigorously. To permit the use of blank cartridges and blank cartridge pistols at any time is little less than criminal.

WILLIAM JAMES

The death of Prof. William James, the eminent psychologist and writer, removes a distinguished member of the medical profession, though the fact that he was a member of our profession may not be generally known. Dr. James graduated from Harvard Medical School in 1869 and from 1872 to 1880 he taught in that school, first anatomy and later physiology. It was but a short step from physiology to philosophy, which he commenced to teach in 1880; and a still shorter one to psychology, of which he became professor in 1889. stray bullets from the reckless use of firearms by others and 3 deaths resulted. Toy cannon caused 212 injuries including 3 killed, but this year caused no cases of tetanus.

TOTALS IN CHIEF CITIES

Table 8 shows the number reported killed and injured in our largest cities during each of the past three years. The population figures are from the United States Census Bureau's estimate for 1909. This table is of particular interest since by it the results of the adoption and enforcement of prohibitive or restrictive ordinances can be seen. Sometimes, however, although very small numbers of injuries are reported, more deaths resulted than in other cities having many more injuries. Pittsburg and New York City each reported six deaths, the largest number this year; Chicago and Philadelphia each report 4 deaths; Cincinnati and Milwaukee each report 3; and Wilkes-Barre, Pa., reports 2. Pittsburg had one more death than last year regardless of the fact that the number of injuries was reduced by half. Although Chicago had only half as many injuries as last year, nevertheless there were four deaths his year to none last year. New York had three deaths less than last year and only $\frac{1}{3}$ as many injuries were reported. For the first time in four years St. Louis and Boston report no deaths and the returns show greatly reduced casualties. Of non-fatal injuries this year, Philadelphia leads with 405, followed by New

sachusetts this year had only about 1/7 of the injuries it had last year; Missouri, New Jersey and New York reduced their injuries to 1/3 and Illinois and Ohio had 1/2 of their last year's totals. Pennsylvania reduced its total to 2/3 of what it had last year. Of all the states having over 100 injured, only Indiana, Iowa and Wisconsin show larger totals than last year. Pennsylvania continues in the lead with 623 injuries, followed by New York with 327 and Illinois with 285. Note that last year the same three states had respectively 986, 897 and 546 injuries! Altogether there were 2,923 injuries this year, a little more than half of last year's record.

NON-FATAL INJURIES

There were 2,792 non-fatal injuries this year, a little more than half (55 per cent.) of the total reported last year. Only 7 persons were totally blinded this year, but 33 lost one eye each, 26 lost legs, arms or hands and 114

lost one or more fingers. The giant firecracker—which, by the way, has a much shorter fuse than the smaller varieties—holds the first place as a cause of mutilating wounds and is responsible for most of the losses of eyes, hands and fingers. In the awfulness of its destructiveness the giant firecracker is equaled in a few instances only by the explosion of bombs, or of home-made cannon. The fact that the wounds made by giant firecrackers are so lacerated is probably the reason they do not cause more lockjaw. Again, these cases are taken to the physician, while the supposedly insignificant wounds made by blank cartridges are not. This year 1,050 injuries including 2 deaths and 2 cases of lockjaw were due to the giant firecracker.

Firearms caused 229 accidents this year including 19 killed and 5 cases of lockjaw. The percentage of deaths from this cause was 10.2. Of the total number thus injured, 78 were struck by

\$10,000.—The Harbor Emergency Hospital, San Francisco, has moved from its old location on the bulkhead at the foot of Mission Street to the new quarters on Clay Street.—Ground for the new Kings County Hospital at Hanford was broken August 11.

Personal.—Dr. H. B. Graham, who recently returned to Berkeley from Austria, has been appointed assistant professor of hygiene in the University of California.—Dr. John T. Jones, Grass Valley, who has been in Europe for a year and a half under treatment for injuries sustained while swimming at Coronado Beach, has sailed from Liverpool for America.—Dr. Fred P. Clark, superintendent of the Stockton State Hospital, has been reelected for another term.—Dr. Frederick P. Gay, of Harvard Medical School, has been appointed head of the department of pathology of the University of California, vice Dr. Alonzo E. Taylor, resigned.—Dr. Thomas W. Huntington, San Francisco, has been appointed chief surgeon of the Western Pacific Railroad.

COLORADO

Personal.—Dr. Elmer A. Elder has succeeded Dr. Joseph E. Peairs, resigned, as city physician of Pueblo.—Dr. A. M. Foster, formerly head of the Eudowood Sanatorium, near Towson, Md., has assumed active charge of Cragmore Sanatorium, near Colorado Springs.

To Better the Health of Pueblo.—A committee has been appointed by the Commerce Club of Pueblo with the object of putting the city on a better sanitary basis. The committee is composed of Drs. Franklin E. Wallace, William H. T. Baker, David W. Collins, Crum Epler and Luke McLean, and plans have already been laid for the inspection of dairies, grocery stores, meat shops and other places where it is likely that unsanitary conditions may be found.

GEORGIA

Higher Entrance Requirements.—It is announced that beginning with the session of 1911-12 the Atlanta School of Medicine will require for admission a four-year high-school education, or the actual equivalent as determined by examination. This requirement is to consist of 14 units as defined by the College Entrance Examining Board. Examinations will be given only by some designated educational authority not interested in the college.

IDAHO

Donates Site for Home.—Dr. Mary E. Johnston, Boise, has donated a block of land at Roosevelt Heights, Boise, as the initial step in the establishment of a home for the old people of the state.

Personal.—At a recent meeting of the State Board of Health Dr. Ralph Falk, Boise, was elected secretary, vice Dr. Jesse L. Conant, Weiser, deceased.—Dr. Glenn E. Shawhan, Boise, has been appointed physician of Ada county, vice Dr. Ralph Falk, resigned.

Infantile Paralysis Epidemic.—The secretary of the State Board of Health has sent out circular letters of inquiry to physicians throughout Idaho asking statistics regarding the alleged prevalence of anterior poliomyelitis in the state. Of the 36 cases reported in Idaho, 7 are said to have occurred in Cottonwood.

ILLINOIS

Personal.—Lieutenant-Colonel Henry Richings, Rockford, surgeon of the Third Brigade, Ill. N. G., has been placed on the retired list.—Dr. Anthony G. Wittman, Blue Island, has passed the civil service examination for assistant physician in the state charitable institutions.

Chicago

Personal.—Dr. William J. Butler has returned from Europe.—Dr. Thomas M. Leahy has passed the state civil service examination for assistant physician in the state charitable institutions.

Sputum Examination.—Improved methods of sputum examination have been adopted recently in the Municipal Laboratory. Sputum shakers of the Boston Board of Health type have been installed and the use of alkaline sodium hypochlorite as digestant has been introduced, resulting in increase in the delicacy of the test and augmentation of the capacity of the laboratory. During the four months prior to the installation, tubercular bacilli were found in 17.5 per cent. of the 1,017 specimens examined, and in the three months following the installation, 27.1 per cent. of tubercular bacilli were found in 506 specimens of sputum.

INDIANA

Transferring Insane Patients.—During the last week five trains transferred 500 insane patients from the Central Insane Hospital, Indianapolis, to the Southeastern Insane Hospital, Madison. This institution comprises a group of thirty-two buildings, overlooking the Ohio River, recently constructed at a cost of \$1,500,000. Dr. Edward P. Busse, Evansville, has been selected as superintendent.

Bureau of Health Speakers.—The State Board of Health is about to establish a bureau of speakers on health. These speakers will accompany the tuberculosis exhibits which are to be sent to schoolhouses, and will speak to the school-children on how to live and how to prevent disease. The lectures will be illustrated and photographs of correct living and sleeping apartments and other methods of sanitation will be shown.

Fort Benjamin Harrison.—During September, 15,000 soldiers of the army militia from Illinois, Wisconsin, Michigan, Ohio, Kentucky and Indiana will assemble at Fort Benjamin Harrison, near Indianapolis, for a tour of inspection and duty. The chief medical officer is Colonel L. Merwin Maus, Medical Corps, U. S. Army, chief surgeon of the Department of the Lakes, Chicago, who has announced that prevention of disease by relentless warfare on the housefly will be the chief work of his department.

Health Car Caravan.—A health car caravan is being organized in Indianapolis by the father of a tuberculous child. The caravans will contain twelve vans and two automobiles with accommodation for from forty to fifty patients suffering from tuberculosis. Nurses, cooks, and a physician are to accompany the caravan. The maximum of out-of-door life will be led. For amusement, fishing, hunting, sightseeing and visiting famous battlefields have been planned. The route includes Kentucky, Tennessee, Virginia, the Carolinas, Georgia, Alabama and Mississippi. The caravan will return to Indianapolis in the spring of 1911.

Violation of Pure Food Law.—During the present term of the Federal Court for the District of Indiana, ten individuals or firms are said to have been fined for violation of the pure food law. Among these were The Wells Medicine Company, Lafayette, for selling "Wells' Dime Headache Cure;" G. R. Summers, South Bend, for misbranding "Mrs. Summers' Harmless Headache Remedy;" "The Sure Pop Company," Terre Haute, for misbranding in the label that "Sure Pop cures headache and neuralgia." The case against the Evansville Bottling works is still pending. This company is said to use cocaine in "Shelburn's Cola." The common violations of the law in the state are misbranding of the weights of cheese, adulteration of vinegar, cottonseed meal, and whisky, and false labeling in shipments of apricots.

IOWA

Personal.—Dr. Harry J. James, formerly superintendent of the State Sanatorium, Oakdale, has been appointed superintendent of the South Dakota State Sanatorium.—Dr. Herbert S. Miner, superintendent of the State Hospital for Inebriates, Knoxville, has resigned, to take effect in November.—Dr. Charles W. Carr, Denison, has returned from Europe.

Woman's Infirmary Opened.—The new Woman's Infirmary in connection with the State Hospital for the Insane, Mount Pleasant, was recently opened to receive patients. The building has been erected at a cost of \$67,500 and has a thoroughly modern equipment, including hydrotherapeutic department, installed at a cost of \$3,500. The building will accommodate 70 patients.

KENTUCKY

Attempted Assassination.—Dr. James U. Ridley, Robard, was shot by a negro, August 24. No cause has been advanced for the attempted assassination.

Personal.—Dr. Henry E. Tuley and family have returned from a ten weeks' trip abroad.—During the illness of health officer Dr. William V. Neel, of Henderson, his duties as health officer have been assumed by Dr. J. W. Stone, president of the board.

Tuberculin Test.—The State Board of Health will probably hold an early meeting to amend its ruling as to the use of the tuberculin test in all dairy cattle furnishing milk for sale in Kentucky, to include cows furnishing milk for manufacture of butter. The board has received an opinion from its attorney

in which it is stated that the board has full power to supplement its order of a year ago to include milk used for all purposes.

Personal.—Dr. Ernest B. Bradley, city bacteriologist of Lexington has been elected health officer of Fayette county. —Dr. Henry B. Ritter has retired from the Medical Department of the University of Louisville and has discontinued the practice of obstetrics. —Dr. Thomas C. Evans has abandoned the practice of his specialty, the diseases of the eye, ear, nose and throat, and is devoting his entire attention to his work as dean of the Medical Department of the University of Louisville.

Merger of Colleges.—The Southwestern Homeopathic Medical Hospital and College of Louisville has been merged with the Hahnemann Medical College of Chicago. The Southwestern Homeopathic College was established in 1892 and the present faculty, the majority of whom are graduates of the institution, will make occasional trips to Chicago to lecture in the Hahnemann College. The college has not been self-supporting recently and its annual deficit has been made up by friends and patrons of the institution. The intern staff at the City Hospital will now be made up exclusively of regular graduates of the University of Louisville Medical Department. Every fifth patient admitted to the institution heretofore has been under the homeopathic service.

MARYLAND

Baltimore

Osler in Baltimore.—Dr. William Osler, regius professor of medicine in Oxford University, England, visited Baltimore August 21, as the guest of Dr. Thomas B. Futeher. He returns to England, September 6.

Personal.—Dr. H. Quigg Fletcher, of Johns Hopkins Hospital, has been appointed house physician at the Union Protestant Infirmary. —Dr. G. Milton Linthicum, who has been ill in the Maryland General Hospital for several weeks, has gone to Atlantic City to recuperate.

Medical Illustrator Dies.—Mr. August Horn, for many years connected with the gynecologic department of Johns Hopkins Hospital as an illustrator of medical subjects, died in Nauheim, Germany, August 19, aged 41. His excellent work has appeared in THE JOURNAL many times.

MICHIGAN

School Medical Inspectors in Saginaw.—The committee of the board of education which has charge of medical inspection of public schools has decided that four physicians shall be employed, each to have three schools under his jurisdiction which must be visited at least once a week.

Personal.—Dr. Frank W. Smithies, Ann Arbor, has been offered a professorship and the directorship of University Hospital in the Iowa State University. —Dr. G. Carl Huber, Ann Arbor, has been made research professor of embryology in the Wistar Institute, Philadelphia. —Dr. Robert M. Gubbins, Ceresco, fell from the roof of his store, August 23, dislocating a wrist and fracturing the left ulna.

MINNESOTA

Personal.—Dr. Nathan C. Bulkley, formerly of Superior, Wis., has been appointed health commissioner and school inspector of Eveleth. —Dr. Clyde E. Prudden, Duluth, has been placed in charge of the school inspection work of Hibbing.

The New Duluth Dispensary.—Dr. William M. Hart, secretary of the St. Louis County Sanatorium, has been placed in charge of the work connected with the new free dispensary. Many patients suffering from tuberculosis have already appeared for examination and treatment.

MISSISSIPPI

Bulletin on Tuberculosis.—The Mississippi State Board of Health has issued a bulletin relative to the war being waged on tuberculosis, in which it gives information regarding the causation of the disease and urges the cooperation of all citizens in preventing its spread.

Personal.—Dr. Francis M. Sheppard, Richton, has been appointed railroad commissioner of Mississippi. —Dr. Harold B. Wood, of the University of Pennsylvania, has been appointed bacteriologist and director of the laboratory of the Mississippi State Board of Health. —Drs. Walter H. Rowan, Wiggins, and James B. Bullitt, University, have been appointed field agents and special inspectors of hookworm and tuberculosis.

—Dr. Roland W. Hall, Clinton, has been appointed by the State Board of Health local sanitary agent for the investigation and eradication of hookworm.

NEW YORK

Off for Europe.—Dr. and Mrs. George A. Chapman, Glens Falls; Dr. and Mrs. Henry A. Gribbon, Poughkeepsie, and Dr. John H. B. Denton, Freeport, have sailed for Europe.

Hostlers Contract Glanders.—Two hostlers are very ill with glanders at Poughkeepsie. It is believed that they contracted the disease from infected horses, twenty of which were shot. A dozen more are isolated and under inspection.

New York City

Lutheran Hospital Plan.—The Lutherans of New York are working for the erection of a hospital to be used especially for the Lutheran poor. The Lutheran Inner Mission Society has organized a district medical service, composed of 15 medical men located in the fifteen districts into which Manhattan and the Bronx have been divided for this purpose. The physicians respond to calls sent by ministers or church workers to treat cases in Lutheran families who are unable to pay for medical and surgical aid.

Memorial Fund for the Academy of Medicine.—The will of Mrs. Margaret E. Gray provides a bequest of \$50,000 to the New York Academy of Medicine to establish the Landon Carter Gray Memorial Fund in memory of her husband, who died about ten years ago. She directs that the income be used to purchase books from time to time and that all such books have inserted a book plate which she has designed for this purpose. The will also leaves \$5,000 to Dr. William B. Pritchard and \$3,000 to Dr. John J. McPhee.

Congestion in Manhattan.—Stanley D. Asheed, head of the Department of Civic Design of Liverpool, England, in a recent address before the Commission of Congested Population made the statement that the congestion in Manhattan exceeds by two-thirds that of any European city. He suggested the removal of all factories from the restricted areas and the development of more lines of communication, as measures that will attract people from the congested districts, and strongly urged the necessity for making greater efforts towards decentralization.

Work of Crocker Cancer Research Fund to Begin.—The George Crocker Cancer Research Fund of Columbia University has undertaken to make examination of suspected tissues provided that the physician will furnish the information needed for its statistical investigation of the etiology of cancer. It is hoped that the profession will avail itself of this offer as the early diagnosis of cancer is of inestimable value to the patient and to the profession—and as, at the same time, the statistics thus obtained will be of great value to those engaged in the research work. The Department of Health has agreed to co-operate with the Department of Pathology of Columbia University, and by the middle of October each collection station of the board will be supplied with jars to be used for specimens of tissue suspected to be cancerous.

Milk Committee Plans Work.—Following the announcement that after this season Nathan Straus will discontinue the pasteurized milk stations in this country owing to the persistent attacks of a New York newspaper on milk pasteurization ventures, the New York Milk Committee is seeking funds for the purpose of undertaking an experiment to determine the nutritive value of raw and pasteurized milk. It asks for \$3,000 before the first of October for this work. This committee in its infant milk depots fed a large number of babies during the period of 1908-1909 on raw and pasteurized milk, the milk in each instance coming from the same dairy. They wish to supplement this investigation by a further intensive study of babies under conditions which they can more nearly control and by chemical laboratory study of the nutritive properties of heated milk. Dr. H. S. Sherman, professor of nutrition at Columbia University, has placed at the disposal of the committee the laboratory equipment of that department. Dr. Godfrey R. Pisek will supervise the work and the laboratories of Dr. Charles E. North, chairman of the milk committee's committee on sanitation, bacteriology, and public health have been offered for the bacteriologic and chemical work.

Osteopaths Again Defeated.—In the case of Dr. Charles F. Bandle who applied for a mandamus to compel the Board of Health to grant a burial permit on a death certificate pre-

sent by him, the supreme court has refused the mandamus. The decision was accompanied by the following memorandum:

While the state has wisely allowed the practice of osteopathy, it does not follow that it thereby holds out one, without any practice in surgery or experience in prescribing drugs, as fully qualified to certify the cause of death. Indeed it is not certain that a board of health would be compelled to take the certificate of death of all licensed physicians in the event of an epidemic or the spread of some new and mysterious disease.

Granted that the theoretical education of the osteopath is of a standard equal to that of a doctor of medicine, after he enters on his profession his practice is restricted, so that it does not appear that he can make the tests by examination of blood and tissues by which alone many diseases can be certainly detected.

The sanitary code is discriminatory, but the discrimination is not personal and arbitrary. It is based on a limitation which the osteopath may be said to make for himself, and deprives him of no rights which he ought to exercise consistent with the public safety.

Bequest to Hospital.—By the will of Mrs. Harriet Coles the Presbyterian Hospital benefits to the extent of \$7,500, which is to be used for founding a bed in perpetuity, the rector of St. Paul's Episcopal Church at Glen Cove having the right to nominate the use to which the bed shall be put from time to time.

Buffalo

Personal.—Drs. Harry M. Weed, Herriot C. Rooth, John C. Thompson and wife, and Otto S. McKee have gone abroad.—Dr. Edwin A. Bowerman has been appointed lecturer on hygiene in the University of Buffalo Medical Department.—Dr. Matthew D. Mann, emeritus professor of obstetrics and gynecology, will continue his duties as dean of the faculty.

Anterior Poliomyelitis.—The Department of Health has sent out circulars to all physicians stating that with the increase in the number of cases of anterior poliomyelitis or infantile paralysis, the department deems it wise to take precautions to prevent its spread. Immediate report of all suspicious cases must therefore be made to the department from now on. Although such houses will not for the present be placarded, quarantine must be observed.

OHIO

Campaign Against Blindness.—The State Board of Health, on August 22, inaugurated an active campaign against ophthalmia neonatorum. A letter with a sterilized dropper and a quantity of silver solution was sent by the board to every registered physician of the state, with instructions for use.

Personal.—Dr. Charles A. L. Reed, Cincinnati, sailed for Europe, August 18, to attend the International Congress on Gynecology and Obstetrics.—Dr. Dudley P. Allen, Cleveland, for many years visiting surgeon at Lakeside Hospital, has resigned from the staff, and from his chair in the Medical Department of Western Reserve University, has given his library to the Cleveland Medical Library, disposed of his instruments and appliances, retired from practice, and with Mrs. Allen, sailed for Europe, August 9.—Dr. Charles T. Swaney, Niles, has announced that he is about to give up practice, and will take charge of a department of the Massillon Rolling Mill Company.—Dr. Benjamin C. Bernard has been appointed a member of the Alliance Board of Health.—Dr. James Donnelly, Toledo, is reported to be critically ill with typhoid fever at St. Vincent's Hospital.—Dr. Samuel C. Nieman, senior-assistant surgeon at the National Military Home, near Dayton, has resigned, and will practice in Cincinnati.

OREGON

Personal.—Dr. Max F. Clausius, physician of the United States Indian Service at Siletz, is taking a vacation trip through Alaska and British Columbia.—Dr. Charles G. Sabin has been appointed city bacteriologist of Portland, vice Dr. Ralph C. Matson, resigned.

State Society to Meet.—The thirty-sixth annual meeting of the Oregon State Medical Association will be held in Portland, September, 7, 8, 9, under the presidency of Dr. Edward A. Pierce, Portland. At the public meeting addresses will be delivered by Dr. Walter T. Williamson, Portland, on "The Value of Exercise and Rest to the Public Health;" by Dr. Charles J. Smith, Pendleton, on "School Hygiene;" by Dr. Andrew C. Smith, Portland, on "The Value of Pure Food," and by Dr. Calvin S. White, Portland, on "The Relation of Pure Water to Public Health."

Sanatorium Soon to be Opened.—It is announced that the State Tuberculosis Sanatorium, near Salem, will be opened the first week in September, under the charge of Dr. Harvey J. Clements, superintendent and medical director. The pres-

ent capacity of the sanatorium is 50 patients, which will be apportioned to the various counties in their ratio to population. The sanatorium is located on the west slope of the hill 5 miles southeast of Salem, protected from north and east winds, at an altitude of 400 feet above the sea. The brick building on the site formerly occupied by the Mute School will be used as headquarters and modern cottages and ideal sleeping porches have been constructed.

PENNSYLVANIA

Stamp Sale to Benefit Hospital.—The directors of the Jewish Sanatorium for Consumptives, Eaglesville, expect to sell one million stamps at the time of the Jewish New Year. These will be sent to stores, lodges, societies and individuals, and their sale will assist the movement to erect a children's pavilion.

Milk Adulterators Arrested.—Embalming fluid, having formaldehyde as one of its chief ingredients, has been found by the agents of the State Dairy and Food Commission in milk sold to the trade in Allegheny County. Informations have been laid against 17 dealers charged with adulterating milk and cream. These men have been arrested and await hearing.

Personal.—Dr. Kerwin W. Kinard, Lancaster, has been commissioned as a lieutenant in the medical corps of the United States Army.—Dr. George D. Nutt has purchased the Bishop Darlington property in Williamsport, and the building on the property will be remodeled and a hospital established. Other local surgeons are associated with Dr. Nutt in this enterprise.

Philadelphia

Cornerstone to be Laid.—The cornerstone of the new building, known as Bradley Hall, to be erected on the grounds of the Methodist Hospital, will be laid with formal ceremonies on September 10. The structure, planned to harmonize architecturally with the rest of the hospital buildings, will contain modern kitchens, refrigerating plant, dining rooms, etc., on the first floor and suites for superintendent and chief resident, rooms for residents and class rooms on the three upper stories.

Personal.—Drs. William W. Babcock, John G. Clark and John Sibbald have returned from Europe.—Dr. Edward Krumbhaar, intern at the Pennsylvania Hospital, is seriously ill with typhoid fever at that institution.—Dr. Algernon B. Jackson has resigned as assistant surgeon to the Polyclinic Hospital to take the position as surgeon-in-chief to Mercy Hospital, an institution conducted for the indigent sick of the colored race.—Dr. James Wallace, formerly chief of the eye department of the hospital of the University of Pennsylvania, left his home on July 31, and has not been heard from since.

Inspectors Seize Goods.—Chief Inspector Jenkins, of the local U. S. Pure Food and Drug Department, ordered on August 23 the seizure of 1,500 pounds of "frou-frou cakes" manufactured by a company of Amsterdam, Holland, and alleged to contain boric acid. The seizure was made at Pennsylvania Railroad Pier 10, where the goods were awaiting delivery to a jobbing house. The inspectors also ordered the seizure of 114 gallons of crushed pineapples at a warehouse at Front and Lombard Streets. The cans, which are said to have contained filthy and decomposed vegetable substance, were shipped in that condition from Hawaii by the Pearl City Fruit Co. At an ice cream factory on South Swanson Street, 19 cases, containing 1,100 pounds of crushed pineapple, were seized. These were shipped by the Pearl City Fruit Co. and the Pineapple City Fruit Co., of Hawaii.

VIRGINIA

Hospital News.—Dr. J. Allison Hodges, Richmond, has purchased a tract of seventeen acres at Westhampton whereon to establish an annex for the Hygiea Hospital for convalescent and rest-cure patients.—Work has begun on the annex of the Stonewall Jackson Memorial Hospital, Lexington.

New Medical Association.—The Shenandoah Valley Medical Association with a membership including every county of the Seventh Congressional District, was organized August 10: at Winchester, with Dr. Durus D. Carter, Woodstock, president; a vice-president from every county of the district, and Dr. Walter Cox, Winchester, secretary-treasurer.

Free Treatment of Hydrophobia.—The State Health Department has made arrangement whereby persons exposed to rabies and not in a position to pay for treatment at a reg-

ular Pasteur institute, will be treated free of cost. Dr. Ennion G. Williams, state health commissioner, has secured a sufficient supply of serum from the Public Health and Marine-Hospital Service to meet the demand.

Personal.—Dr. Edwin M. Sneed, Garrisonville, has been elected secretary, and Drs. Elliot T. Jett, Fairmouth, and William H. H. Tate, Tackett's Mills, have been appointed members of the board of health of Stafford County.—Dr. Paulus A. Irving, Richmond, announces that he will give up practice and move to Prince Edward County on account of the ill health of members of his family.—Dr. George H. Reese, Franklin County, has been appointed a member of the staff of the Central State Hospital, Petersburg.

WISCONSIN

Bubbler Succeeds Fountain.—In accordance with the state law prohibiting public drinking cups in public, private, and parochial schools and other educational establishments, the board of education of Superior is said to have ordered sanitary drinking fountains to be installed in the public schools of the city.

Society Meeting.—The annual meeting of the Southeastern Wisconsin Physicians' Association was held in Racine, August 17, with about one hundred in attendance. Elkhorn was selected as the next place of meeting. Dr. Edward Kinne of that city was elected president, and Dr. Milton V. De-Wire, Sharon, secretary-treasurer.

Increase in Faculty.—Marquette Medical College has made the following additions to its staff: department of internal medicine, Drs. Robert Brown and William H. Washburn; department of dermatology, Dr. Robert G. Washburn; department of obstetrics, Dr. Gustave A. Hipke, and department of ophthalmology, Dr. James A. Bach.

Anti-Spit Bullets.—The Wisconsin Antituberculosis Association has provided ammunition for use in its war against expectoration in public places. This ammunition is known as an "anti-spit bullet" and consists of a little slip, one side of which contains an appeal to help eradicate consumption from Wisconsin, and the other side a warning from the health officer regarding spitting in public places, its dangers and penalties.

Work of State Laboratory.—During the past year the State Hygienic Laboratory at the State University, Madison, has examined 804 specimens for diphtheria; 1,048 specimens of sputum for tuberculosis; has made 406 water tests; the Widal test in 497 cases, and 407 miscellaneous examinations for anthrax, glanders, blood, and tuberculosis, and 146 examinations for rabies, and has given the pasteur treatment to 89 individuals.

GENERAL NEWS

Cotton-Seed Oil and Butter.—According to the *Daily Commercial Trade Reports* Egypt produces annually about 40,000 barrels of cotton-seed oil, most of which is exported to England or used at home in making soap. The natives, however, have been educated to substitute cotton-seed oil for olive oil and they are large consumers, and 8,000 to 12,000 barrels of the better grades are annually imported from England and the United States. These grades are used exclusively for mixing with olive oil, and it is said that these mixtures are sold as pure olive oil. In Egypt considerable olive oil is also used in making a native butter similar to the Indian product called ghee. This is made by boiling together for a long time cotton-seed oil, mutton tallow, real butter and perhaps one or two other ingredients. It is used largely by the natives instead of butter, and its preserving qualities are remarkable. It is palatable, wholesome and much cheaper than butter.

Public Health Association Meeting.—The thirty-eighth annual meeting of the American Public Health Association, whose membership includes United States, Canada, Mexico and Cuba, will be held in Milwaukee, September 5-9, under the presidency of Dr. Charles O. Probst, Columbus. The meetings will be held in the Milwaukee Auditorium, and the headquarters will be at the Hotel Pfister. The general topics for discussion are "The Relation of the University to Public Health Work," "Methods of Handling State Health Work," "The Inter-Relation of National Organizations Working in the Interests of Health," "Section Reports for General Meeting," "The Present Organization and Work for the Protection of Health in the Four Countries Represented in the Association," "Sanitary Engineering Questions," "The Prevention of Mental Defects and Mental Diseases," "The Relation of Unnecessary Noises to Health," and "The Necessity for Terminal Disinfection and Quarantine."

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Aug. 20, 1910.

Lowest Birth-Rate and Death-Rate on Record

The decline of the birth-rate is so continuous that many times the "lowest on record" has been reported in THE JOURNAL, and this must be done once more. According to the quarterly return the population of the United Kingdom in the middle of 1910 is estimated at 46,469,534, of whom 36,169,150 live in England and Wales. In these countries the birth-rate is in the proportion of 26 per 1,000 annually. This is 2.1 below the mean birth-rate of the 10 preceding second quarters and is the lowest recorded since the establishment of civil registration. The death-rate was in the proportion of 12.8 annually per 1,000. This is 2.3 below the mean rate for the last 10 years and is also the lowest on record. Infantile mortality measured by the proportion of deaths under one year to registered births was 91 per 1,000. This is 19 below the average of the ten preceding years and again the lowest on record. The causes of these declining figures have been fully discussed in previous letters.

Exposure of a Quack

One of the worst and most heartless features of quackery is the exploitation of such diseases as tuberculosis and cancer, which are unamenable to drugs. In Great Britain, it is but seldom that the law takes any notice of the most fraudulent promises of cure. Indeed, the government, by levying a stamp duty on all secret remedies, has made itself to a certain extent *particeps criminis*. The following case is happily an exception to the usual immunity of the quack: C. H. Stevens, of Wimbledon, who described himself as "an unregistered lung specialist," was sued by a woman for \$50, a sum which he promised in his advertisements to any patient whom he did not cure of consumption. The woman's husband was treated by him and died of pulmonary tuberculosis. Stevens denied any contract to pay \$50 in case of failure and said that the advertisements offering this sum did not appear until after the man's death. After evidence showing that he carried on an extensive business at Wimbledon, and had "Consumption and Lung Specialist" on a brass plate and that he offered the widow \$5 to withdraw the case he was closely pressed by the judge as to the composition of his "medicine" and its curative merits. After heated protests and much hesitation he said that he studied the curing of consumption under Dr. Stuart, of Somerset Hospital, Cape Town. Fifteen years ago, by accident, he came across a native remedy at Maseru, Basutoland. A native "doctor" showed him the plants from which it was made. Under pressure he declared that he still imported these Basuto plants into Wimbledon, but he could not say when the last consignment arrived. The judge suggested that the railway books could be consulted. Stevens said that he had been making the \$50 offer since last September, but had not yet paid it for a case of failure. The reason was that he had cured every patient except one. In giving judgment for \$50 in favor of the widow the judge said that the case was one of a class which was of the gravest importance to the public. Quack remedies were constantly put forward by imposters to play on the fears and hopes of despairing sufferers. In this case, there had been intentioned and well-considered fraud. It was a scandalous thing that poor people should be imposed on by a quack preparation of not the slightest use. He ordered the letters and documents in the case to be impounded. This is done with a view to their consideration by the public prosecutor. In the case of another quack preparation for consumption which was taken by a boy up to the time of his death a coroner made similar severe remarks and suggested a criminal prosecution (reported in THE JOURNAL) but none followed. The government does not appear to be alive to the criminal nature of these frauds and at present all that can be hoped is that they will be made amenable to the civil law.

Blind Masseurs for Patients Suffering from Beriberi

At the Seamen's Hospital, Greenwich, Mr. J. Canlie has introduced massage with Swedish movements for the treatment of beriberi. Following the example of the Japanese, the massage is performed by blind operators whose highly developed sense of touch is of great value in handling delicate patients. So far, the treatment has proved successful in restoring the energy of the atrophied muscles. Two Chinamen

are under treatment who could not put a foot to the ground. After two treatments by massage they began to gain strength and, a week after treatment was instituted, could move about the ward with comparative freedom.

The Milk Supply of London

In his annual report, Dr. Collingridge, health officer for the City of London, states that the inquiry into the character of the milk arriving in London has gone on since 1902. Of 32 samples examined bacteriologically 14 were fairly clean and pure, 14 unclean, and 4 tuberculous. This was the largest proportion of tuberculous milk found since the beginning of the inquiry. In 3 of the farms whence this milk came the cows were found suffering from tuberculosis of the udder or generalized pulmonary tuberculosis. A large proportion of the samples of milk—90 per cent.—contained dirt. Few precautions were taken to prevent contamination of the milk by dirt and other impurities. This can never be entirely obviated while the old, badly designed churns are in use, but many farms are now adopting an improved pattern designed for the exclusion of aerial and other contamination. From other returns it is evident that an enormous quantity of tuberculous milk is distributed throughout the country and a still larger proportion is contaminated with other pathogenic organisms. Owing to neglect of elementary precautions at dairy farms, supplies more often than not are contaminated by the cows. The recent commission on tuberculosis has shown that a considerable amount of disease, especially in infants, is due to tuberculous milk.

Florence Nightingale

On August 13, Florence Nightingale, the pioneer of scientific nursing and one of the heroines of British history, died in her ninety-first year. She was the daughter of a country gentleman of considerable wealth. Even when a child she showed extremely strong sympathies, quick apprehension and excellent judgment, and at the same time was the consolator and benefactress of all the villagers on her father's estate. She was carefully educated in classics, mathematics, and modern languages. She visited the hospitals in London, Dublin, and Edinburgh, and many country hospitals, as well as naval and military ones. She studied nursing on the continent at Paris under the *Sœurs de Charité* and at the Institute of Protestant Deaconesses at Kaiserwerth on the Rhine. On returning to England, she was appealed to on behalf of the Home for Sick Governesses, in London, which was languishing for want of support as well as management. She took over its control and devoted to it time, energy, and fortune, and re-established it on a sound basis. Thus unconsciously she spent 10 years in preparing for the great event of her life. When in 1854 the battle of Alma was fought in the Crimea, the reports of the condition of the sick and wounded sent a feeling of horror throughout England. The commonest accessories of a hospital were wanting; the sick had to be attended by the sick. Miss Nightingale wrote to the Secretary of War offering to go out and at the same time her letter was crossed by one from him asking her to go "as the only person in England capable of organizing and superintending a scheme for nursing the wounded soldiers." Within a week she had selected from hundreds of offers received from all parts of the country a staff of 38 nurses, including 10 Anglican sisters and 10 Roman Catholic Sisters of Mercy. On arrival, they found at Scutari 2 hospitals containing 3,000 men under appalling conditions. Neglect, mismanagement and disease rendered the scene one of unparalleled hideousness. The wounded lay on beds placed on the pavement and were bereft of all comforts. There was a scarcity alike of food and medical aid; fever and cholera were rampant. Even the slightly wounded who should have recovered under proper treatment were dying from lack of proper nourishment. Miss Nightingale at once set to work to evolve order out of chaos. Within 10 days she had an impromptu kitchen fitted up and a house near the hospital converted into a laundry, which was sorely needed. To the sick and wounded she was indeed a ministering angel and her services excited unbounded devotion. When the medical officers had retired for the night she made her solitary rounds alone among the sick and dying with a little lamp. As her fragile figure passed by the soldiers' faces softened with gratitude. In spite of delicate health she was known to stand 20 hours on the arrival of fresh detachments of wounded, apportioning quarters, distributing stores, and directing her staff. During the first 7 months of her stay in the Crimea the mortality was 60 per

cent. per annum from disease alone, but later this was much reduced. After the war a fund was established as a national commemoration for her services and yielded an income of \$225,000. It was devoted to setting up a training school for nurses at St. Thomas' Hospital and to the maintenance and instruction of midwifery nurses at King's College Hospital. But for herself she would have neither public testimonial nor public welcome. Her fame was on every lip and her name a household word among the peoples of the world, but her life ever after was little better than that of a recluse and confirmed invalid. Though physically weak, her mental strength was great and she remained devoted to the cause of nursing. She was the general adviser on nursing organization not only of her own but of foreign governments and was consulted by ministers and generals at the outbreak of all our wars, and expounded important schemes of sanitary and other reforms. She was the means of inspiring more humane and more efficient treatment of the wounded in the American Civil War and in the Franco-German War. The nursing school at St. Thomas' Hospital proved very successful and led to the establishment of the numerous schools which now exist throughout the country. She wrote much and well on nursing. Her book "Notes on Nursing" was so clear and practical that 100,000 copies were sold.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Aug. 19, 1910.

Twentieth Congress of Alienists and Neurologists of France and French-Speaking Countries

The above-named congress was held in Brussels, August 1 to 7. Three questions were discussed: (1) sleeping-sickness; (2) cutaneous lesions in mental and nervous affections, and (3) alcoholism and criminality.

SLEEPING-SICKNESS

Dr. Van Campenhout, professor at the Brussels school of tropical medicine, read a paper on this subject, emphasizing the rôle of the *Glossina palpalis* as an indispensable factor in the propagation of the disease. Transmission by sexual relations conceded by Koch, is impossible. In America, the trypanosome has never been transmitted to American-born women. The numerous Europeans who have returned infected with trypanosomiasis have never caused a single European case of sleeping-sickness.

The diagnosis of sleeping-sickness is easy at the second and the third stages, but not at the first. As Dr. Granjux said in the course of the discussion, it is most important that the diagnosis should be made early, not only because of the greater chances of cure, but also because, in proportion as sleeping-sickness is understood better and recognized earlier, psychic troubles are more and more frequently found present at the outset, constituting, Granjux believes, a "medicolegal" period, during which the patient is liable to various errors of judgment which may involve serious consequences. This being the case, every individual who has sojourned in a region infested by the tsetse fly and who presents symptoms analogous to those of general paralysis should be examined for the trypanosome, whether or not he happens to be syphilitic.

ALCOHOLISM AND CRIMINALITY

This question was the subject of a paper by Dr. A. Ley, head physician at the sanatorium of Fort Jaco, Uccle, and Dr. René Charpentier, head of the clinic of mental diseases at the Paris college of medicine, who first cited numerous statistics showing the influence alcoholism has over criminality.

The statistics of the Ste. Anne Asylum at Paris are particularly instructive. Out of 885 offenses and crimes for which 801 patients were confined in this establishment from 1905 to 1909 inclusive, 370, or 41.8 per cent., were attributable to various forms of alcoholism. In Scotland and Ireland, the number of arrests for inebriety have diminished with the diminution in the number of hours that the public-houses are allowed to remain open; and Sunday criminality has diminished markedly since the complete closing of places for the sale of alcoholic drinks has been made compulsory on that day.

The present laws of Belgium and France on the subject of criminal inebriety, the essayist remarked, are inefficacious and insufficiently enforced. When an offense or crime due to alcohol is committed, the accused is subjected to

medicolegal examination and adjudged either irresponsible or semiresponsible; in the first case he is put in confinement; in the second there is a diminution of the penalty. In either case, the results are bad, both legally and medically. Legally, the penalty is not sufficiently exemplary; medically, the period of the moral treatment of the criminal is too limited. Special establishments are necessary in which criminal inebriates may be judicially confined. Such institutions exist in many countries and are provided for by the new bill which has passed the French Chamber of Deputies. It was in Switzerland, where there are now twelve such establishments, that asylums for inebriates were first founded. Great Britain, the United States, New South Wales and New Zealand have recognized the uselessness of the temporary confinement of delinquent inebriates in prisons, and have founded special asylums (reformatories) for such criminals, discharge from which is granted only on a solemn promise of total abstinence. Thirty to 50 per cent. of cures are recorded. All those who have had any considerable experience with asylums for inebriates agree in saying that only a course of total abstinence, lasting from six months to two years or more, is capable of effecting cures. The work-cure ought to be methodically applied. Allowing inebriates in asylums to become inactive or lazy should be avoided by all means. The physicians and all the members of the staff of an asylum for inebriates should be total abstainers, for mere temperance does not afford a proper example.

In reviewing the measures of social prophylaxis, Drs. Ley and Charpentier emphasize particularly the rôle of local option, showing how, in the United States, many of the southern states have been able to attain prohibition without undue friction by local option. By examples from the United States, the essayists show that criminality waxes with the sale of alcoholic drinks, and wanes with its suppression. Thus in New Hampshire a period of license following a period of prohibition gave the following figures for the increase in the numbers of those committed to penal institutions:

1902 (last year of non-license).....	473
1903 (first year of license).....	838
1904 (second year of license).....	1,337
1905 (third year of license).....	1,637
1906 (fourth year of license).....	2,181

Drs. Ley and Charpentier concluded that the broadest and most fertile field of experience for social measures against alcoholism is at present found in the United States of America, where all systems are put in practice: monopoly, high license, restriction of the number of saloons, closing on certain days, concentration in one quarter of the city, local option and prohibition. There is, moreover, a struggle going on there between the saloon interests, which wield a considerable power, and the prohibition party, which is carrying on an enthusiastic and active propaganda.

Louis Farabeuf

Dr. Louis Hubert Farabeuf, former professor of anatomy at the Paris college of medicine and member of the Académie de Médecine, has just died, aged 69. Appointed head demonstrator in anatomy at the Paris college of medicine in 1878, he became, nine years later, professor of anatomy and occupied this chair until 1902, when he retired and was replaced by Poirier. While the latter was not only an anatomist, but a surgeon whose practice increased so as to be somewhat prejudicial to instruction, Farabeuf was devoted exclusively to instruction, for which he had extraordinary gifts, his lessons being of remarkable clearness and definiteness. The same qualities were found in his monograph on the blood-vessels of the perineum and the pelvis, published in 1905 and his "Introduction to the Clinical Study and Practice of Obstetrics," published in collaboration with Dr. Varnier, in 1891; but the book which brought Farabeuf his greatest reputation was his "Précis of Operative Technic," comprising the operative technic of ligatures, amputations and resections, which has had several successive editions since 1872, the last having been published in 1909. This work is a veritable masterpiece of clearness and precision.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, August 11, 1910.

Personal

At the end of the summer semester, Professor Riedel, director of the surgical clinic at Jena, resigned his position. Riedel had to undergo an amputation for arteriosclerotic gangrene six months ago.

Another X-Ray Victim

A victim to x-ray cancer like the London physician Cox, who lately died of this disease, is furnished by Prof. Albers Schönberg, the well known x-ray investigator at Hamburg. He acquired an ulceration of the skin during his early studies before the injurious action of the Roentgen rays was known. This eventually underwent malignant degeneration and recently necessitated the amputation of his left forearm. Some fingers of the right hand are also crippled. Other x-ray investigators have chronic incurable skin affections. Sterility occurs in consequence of exposure to the Roentgen rays more frequently than is generally known.

International Thalassotherapy Congress

The Fifth International Congress for Thalassotherapy will meet at the well known German watering place on the Baltic, Colberg, in Whitsunday week of next year. Dr. Foerster, the director of the Prussian medical bureau, has the presidency of the German committee.

Organization of Rescue Work in Mines

The numerous severe catastrophes that have occurred in the last few years in the mines of various countries have compelled the authorities to give attention to the development of a life-saving service for mines. In Germany for a long time much attention has been given to the manufacture of life-saving apparatus. The management of many mines have trained special rescue crews for their mines and in some mining districts rescue emergency stations have been established. A further development of this organization is now contemplated in one of the largest mining districts of Germany, the Rhenish-Westphalian anthracite coal districts. In this district where already the individual mines possess 7,000 sets of rescue apparatus and 2,500 trained men in the rescue crews it is planned to establish a central station for the mine rescue service. This bureau is to keep in stock the apparatus for rescue of miners, and to supervise the training of the men from all the mines. This supervision is to be carried out by expert officers. In order to keep the training of the crews at its highest efficiency, the officers of the rescue stations are occasionally to take part in the exercises of the rescue crew. A further function of the bureau is the testing and reporting on new forms of apparatus and other branches of rescue work.

The Campaign Against Pulmonary Tuberculosis by the Wage-Earners' Insurance Organizations

According to official statements, 42,000 persons were treated for pulmonary tuberculosis in 1909 by the German invalid insurance societies. In order to determine the results of the treatment of tuberculosis in the public sanatoria, the imperial insurance office instituted investigations as to how many of the persons treated in the sanatoria were able to work five years after their dismissal. It was found that in the period of treatment from 1897 to 1901, at the end of the period 25 per cent. of the men and 32 per cent. of the women had their earning capacity restored. At the end of the period from 1904 to 1908, on the other hand, 44 per cent. of the men and 51 per cent. of the women were still able to work. The results of the treatment have markedly improved in recent years. The statistics also show that even patients in the third stage of tuberculosis (according to the classification of Turban and Gerhardt) are favorably influenced by the public sanatoria; of 3,590 men in the third stage, 1,649, that is, 47 per cent., were able to work on dismissal, and of these 553 have passed into a more favorable stage. Of 9,160 men in the second stage, 85 per cent. were able to work.

Study of Epizootics in German Southwest Africa

Professor Ostertag, the director of the veterinary department of the imperial health office, has been sent out by the imperial colonial office for the study of epizootic diseases in German Southwest Africa. He is to gather information by investigations on the ground respecting the character and the control of animal pestilences, especially that recently observed among sheep. In addition, Professor Ostertag is to make recommendations on the basis of his observations as to the best method of making use of scientific experience regarding animal pestilence by the establishment of appropriate organizations and especially by the development of the existing bacteriologic station.

Health and Vital Statistics of Prussia in 1908

From the report of the medical bureau of the Prussian department of education on the public health for 1908 (which has just appeared) a number of general interesting facts can be learned. The number of births in Prussia was 1,308,283, an absolute increase of 9,902 over the previous year. Of these, 38,884 were stillborn, an increase of 229 over the previous year. The proportion of the living born to 1,000 inhabitants was 32.99, a proportion which is smaller than that of any year previous to 1901. Of 1,000 births in the city, 30.43 were stillborn, but in the country 29.21. Of those born living, 651,426 were males, 617,973 females. The births of male children per 1,000 inhabitants diminished 0.32 over the previous year, that of female 0.15. Of all the births, 16,884 were plural, 16,716 being twins, 167 triplets, and 1 quadruplet. Of 1,000 children born in plural births, 42.31 were stillborn, making 13 more than single births. The number of marriages in 1908 were 311,331, nearly as many in the towns as in the country. (Prussia had a population of 3,293,324 in 1905.)

There were 693,724 deaths in 1908, an increase of 12,775 over the previous year. The excess of living births over the deaths was 575,675, which, with the exception of 1907 and 1906, is more favorable than in previous years. Of 1,000 inhabitants 19.17 male and 17.02 female, or altogether 18.03 persons died, a figure more favorable than in all previous years. The mortality in large cities of over 100,000 inhabitants remains on the average, 16.51 per 1,000 living, below the average of the entire nation (18.03). The highest mortality is shown by the city of Posen (22.24), the lowest by the city of Schöneberg (11.44). Berlin had a death-rate of 15.42.

Miscellany

Military Psychiatry.—An interesting article by R. L. Richards, Captain Medical Corps, U. S. Army, on military psychiatry, appears in the *American Journal of Insanity* for July. He reviews the practice in foreign countries as regards the insane in the military and naval services and credits Russia as having been in some measure a pioneer in this matter. That country also gave the first practical demonstration of the necessity and importance of a complete psychiatric service from the firing line to the home hospitals in the late Japanese-Russian war. Most countries give more or less psychiatric instruction to military surgeons, the United States being about the last in the field. Psychiatric instruction is now being afforded to army medical officers in the Government Hospital for the Insane, Washington, D. C., which offers special advantages for this purpose. The most important problems confronting military surgeons in this regard are the special character of the insane patients that will come under their charge, the specially dangerous character of insanity occurring in certain military situations, the peculiar liability to it under the conditions of special stress which the soldier undergoes, and the necessity of proper scrutiny of recruits. The military insane are younger in years and show a higher recovery rate. The special conditions of exhaustion, specific poisons, etc., produce a comparatively simple form of mental disturbance tending to early recovery. A large number of men recover before reaching the home hospital. On account of the nature of military life the insane are potentially dangerous to a large number of people. An insane man in a regiment is a weak point in the line and this is especially true with the complicated organization of armies in modern warfare. Any physical or psychical weakness also comes to the front under such conditions. During the Russo-Japanese war the insane were seen wandering around everywhere in the battle line in spite of the best organization that the world has ever seen (Oserezkowski: *Militärwochenblatt*, 1906, No 140). In one instance a whole regiment was put into a panic which could only be explained by psychic infection from some mental weaklings. There is no way of preventing the presence of some such in a battle. Richards' investigations show that of the military insane received at the Government Hospital for the Insane, 13 per cent. had had previous attacks of insanity; 60 per cent. showed degenerative stigmata and 15 per cent. had had suspicious symptoms

in their history. An appreciable proportion of the military offenders of the army are also to be classed among the psychic weaklings. The remedies for the conditions mentioned are simple in principle but somewhat difficult of application. Other countries are more strict in this regard than ours. The standard of mental efficiency fixed by Congress for an enlisted man is simply that he must "speak, read and write the English language" and take out his first citizenship papers. We have not, in this country, the police records, the school reports, etc., which are available in European countries, and we have to depend largely on the three months observation at the recruiting station to determine the fitness of the man for military service. In spite of all care, it is everywhere found impossible to prevent some incompetents passing the scrutiny. The question of establishing the degree of responsibility of the service for mental disability presents unusual difficulties from the fact that the etiology of mental diseases is not by any means usually clear. Hence the difficulty in case of application for pensions. It is especially difficult in the early stages of mental diseases during which the military surgeon has the cases under observation. The duty of the military surgeon in helping to establish the degree of responsibility of a military offender on account of mental defects is also mentioned and a knowledge of the conditions of military life is essential in considering these cases. The military surgeon has the advantage of better knowledge of the previous conduct of the offender under military conditions. The point has been made by a German authority that the legal, rather than the medical, standpoint must be taken since a military offense is relatively more serious and the effect on the regard for authority among the other soldiers is more dangerous than in civil life.

Disposal of Excreta.—Reporting his experiments on the disposal of excreta (*Public Health Reports*, Aug. 19, 1910), Dr. C. W. Stiles declares that if night soil containing fly larvæ is taken from surface privy and buried in 6½ inches of sterilized sand, the burial of the material does not insure the death of the insects; on the contrary the latter are able to penetrate the sand and to issue as adult flies. This emphasizes the fact that all fecal material should be rendered harmless, and raises doubt in regard to the popular faith in the dry system of disposal of excreta. Burial in 6½ inches of sand does not prevent hookworm larvæ from coming to the surface, and when placed in a 2 per cent. solution of crude phenol in water live eggs were found after 24 hours, but not at the next observation on the twenty-third day. This mixture killed hookworm embryos and larvæ in a few moments, observation being made under the microscope. Fly larvæ were also killed and flies did not oviposit on the floating fecal material treated in this manner, but on account of certain dangers Stiles does not recommend the use of this solution. Even 2 inches of water with a film of kerosene is exceedingly inhibitory to the development of the eggs of both *Ascaris lumbricoides* and *Necator americanus*. Under about 9 inches of water, with a film of kerosene, hookworm eggs begin to die after 4 days. Some may be found alive up to the twenty-ninth day, but no egg was found in the experiments which had developed to the "tadpole" stage. Stiles states that it would be unsafe from the standpoint of hookworm disease to throw the kerosene treated feces on the ground even after they had fermented for 33 days. If water and kerosene are added to a pail containing fly-blown feces, some of the fly larvæ succeed in crawling through the oil and escaping from the pail; but if the water and kerosene are placed in a tub before use, or before the feces become fly-blown, the feeding and breeding of flies, mosquitoes and other insects in the night soil seems to be eliminated, and thus the spread of filth and bacterial infection from the privy tub to food by means of insects appears to be excluded. The chief objections to the water-kerosene method seem to be that if the water is too deep splashing occurs; a tendency to economize may result in the use of too small a receptacle, the wet system calling for a larger receptacle than the dry; the feasibility of applying the method to manure piles in order to prevent the breeding of flies may be doubtful.

medicolegal examination and adjudged either irresponsible or semiresponsible; in the first case he is put in confinement; in the second there is a diminution of the penalty. In either case, the results are bad, both legally and medically. Legally, the penalty is not sufficiently exemplary; medically, the period of the moral treatment of the criminal is too limited. Special establishments are necessary in which criminal inebriates may be judicially confined. Such institutions exist in many countries and are provided for by the new bill which has passed the French Chamber of Deputies. It was in Switzerland, where there are now twelve such establishments, that asylums for inebriates were first founded. Great Britain, the United States, New South Wales and New Zealand have recognized the uselessness of the temporary confinement of delinquent inebriates in prisons, and have founded special asylums (reformatories) for such criminals, discharge from which is granted only on a solemn promise of total abstinence. Thirty to 50 per cent. of cures are recorded. All those who have had any considerable experience with asylums for inebriates agree in saying that only a course of total abstinence, lasting from six months to two years or more, is capable of effecting cures. The work-cure ought to be methodically applied. Allowing inebriates in asylums to become inactive or lazy should be avoided by all means. The physicians and all the members of the staff of an asylum for inebriates should be total abstainers, for mere temperance does not afford a proper example.

In reviewing the measures of social prophylaxis, Drs. Ley and Charpentier emphasize particularly the rôle of local option, showing how, in the United States, many of the southern states have been able to attain prohibition without undue friction by local option. By examples from the United States, the essayists show that criminality waxes with the sale of alcoholic drinks, and wanes with its suppression. Thus in New Hampshire a period of license following a period of prohibition gave the following figures for the increase in the numbers of those committed to penal institutions:

1902 (last year of non-license).....	473
1903 (first year of license).....	838
1904 (second year of license).....	1,337
1905 (third year of license).....	1,637
1906 (fourth year of license).....	2,181

Drs. Ley and Charpentier concluded that the broadest and most fertile field of experience for social measures against alcoholism is at present found in the United States of America, where all systems are put in practice: monopoly, high license, restriction of the number of saloons, closing on certain days, concentration in one quarter of the city, local option and prohibition. There is, moreover, a struggle going on there between the saloon interests, which wield a considerable power, and the prohibition party, which is carrying on an enthusiastic and active propaganda.

Louis Farabeuf

Dr. Louis Hubert Farabeuf, former professor of anatomy at the Paris college of medicine and member of the Académie de Médecine, has just died, aged 69. Appointed head demonstrator in anatomy at the Paris college of medicine in 1878, he became, nine years later, professor of anatomy and occupied this chair until 1902, when he retired and was replaced by Poirier. While the latter was not only an anatomist, but a surgeon whose practice increased so as to be somewhat prejudicial to instruction, Farabeuf was devoted exclusively to instruction, for which he had extraordinary gifts, his lessons being of remarkable clearness and definiteness. The same qualities were found in his monograph on the blood-vessels of the perineum and the pelvis, published in 1905 and his "Introduction to the Clinical Study and Practice of Obstetrics," published in collaboration with Dr. Varnier, in 1891; but the book which brought Farabeuf his greatest reputation was his "Précis of Operative Technic," comprising the operative technic of ligatures, amputations and resections, which has had several successive editions since 1872, the last having been published in 1909. This work is a veritable masterpiece of clearness and precision.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, August 11, 1910.

Personal

At the end of the summer semester, Professor Riedel, director of the surgical clinic at Jena, resigned his position. Riedel had to undergo an amputation for arteriosclerotic gangrene six months ago.

Another X-Ray Victim

A victim to x-ray cancer like the London physician Cox, who lately died of this disease, is furnished by Prof. Albers Schönberg, the well known x-ray investigator at Hamburg. He acquired an ulceration of the skin during his early studies before the injurious action of the Roentgen rays was known. This eventually underwent malignant degeneration and recently necessitated the amputation of his left forearm. Some fingers of the right hand are also crippled. Other x-ray investigators have chronic incurable skin affections. Sterility occurs in consequence of exposure to the Roentgen rays more frequently than is generally known.

International Thalassotherapy Congress

The Fifth International Congress for Thalassotherapy will meet at the well known German watering place on the Baltic, Colberg, in Whitsunday week of next year. Dr. Foerster, the director of the Prussian medical bureau, has the presidency of the German committee.

Organization of Rescue Work in Mines

The numerous severe catastrophes that have occurred in the last few years in the mines of various countries have compelled the authorities to give attention to the development of a life-saving service for mines. In Germany for a long time much attention has been given to the manufacture of life-saving apparatus. The management of many mines have trained special rescue crews for their mines and in some mining districts rescue emergency stations have been established. A further development of this organization is now contemplated in one of the largest mining districts of Germany, the Rhenish-Westphalian anthracite coal districts. In this district where already the individual mines possess 7,000 sets of rescue apparatus and 2,500 trained men in the rescue crews it is planned to establish a central station for the mine rescue service. This bureau is to keep in stock the apparatus for rescue of miners, and to supervise the training of the men from all the mines. This supervision is to be carried out by expert officers. In order to keep the training of the crews at its highest efficiency, the officers of the rescue stations are occasionally to take part in the exercises of the rescue crew. A further function of the bureau is the testing and reporting on new forms of apparatus and other branches of rescue work.

The Campaign Against Pulmonary Tuberculosis by the Wage-Earners' Insurance Organizations

According to official statements, 42,000 persons were treated for pulmonary tuberculosis in 1909 by the German invalid insurance societies. In order to determine the results of the treatment of tuberculosis in the public sanatoria, the imperial insurance office instituted investigations as to how many of the persons treated in the sanatoria were able to work five years after their dismissal. It was found that in the period of treatment from 1897 to 1901, at the end of the period 25 per cent. of the men and 32 per cent. of the women had their earning capacity restored. At the end of the period from 1904 to 1908, on the other hand, 44 per cent. of the men and 51 per cent. of the women were still able to work. The results of the treatment have markedly improved in recent years. The statistics also show that even patients in the third stage of tuberculosis (according to the classification of Turban and Gerhardt) are favorably influenced by the public sanatoria; of 3,590 men in the third stage, 1,649, that is, 47 per cent., were able to work on dismissal, and of these 553 have passed into a more favorable stage. Of 9,160 men in the second stage, 85 per cent. were able to work.

Study of Epizootics in German Southwest Africa

Professor Ostertag, the director of the veterinary department of the imperial health office, has been sent out by the imperial colonial office for the study of epizootic diseases in German Southwest Africa. He is to gather information by investigations on the ground respecting the character and the control of animal pestilences, especially that recently observed among sheep. In addition, Professor Ostertag is to make recommendations on the basis of his observations as to the best method of making use of scientific experience regarding animal pestilence by the establishment of appropriate organizations and especially by the development of the existing bacteriologic station.

Marriages

HOMER PERSELL PROWITT, M.D., to Miss Elinor Meyer, both of Washington, Pa., August 22.

OLIVER PERRY BIGELOW, M.D., to Miss Emma K. Wright, both of Independence, Iowa, August 19.

WILLIAM EDWARD LADD, M.D., Boston, to Miss Helen Katharine Barton, of Worcester, Mass., August 18.

LEO BERTHOLD AUERBACH, M.D., El Paso, Texas, to Miss Harriet Stribling Clark, of Chicago, August 20.

R. GAINSFORTH JAMES, M.D., Gaines, Mich., to Miss Edythe May Stiff, of Ann Arbor, at Windsor, Ont., recently.

Deaths

William James, M.D. Harvard Medical School, 1869; eminent as a psychologist; formerly instructor and assistant professor of physiology; instructor in anatomy; assistant professor and professor of philosophy; professor and emeritus professor of psychology in Harvard University; recipient of honorary degrees from many universities of Europe and the United States; Gifford lecturer on Natural Religion in the University of Edinburgh from 1899-1901; Hibbert lecturer on philosophy in Oxford University in 1908; author of standard textbooks on psychology; one of the founders of the American Society for Psychological Research; founder of the so-called "pragmatic" school of philosophy; of whose literary characteristics it was said that he wrote "science like romance;" died at his summer home in Chochorua, N. H., August 26, from heart disease, aged 68.

Joseph A. Scroggs, M.D. Rush Medical College, 1874; a member of the American Medical Association; emeritus professor of obstetrics in Drake University, Des Moines, Iowa; at one time a member and president of the State Board of Health and State Board of Medical Examiners; president of the Iowa State Medical Society in 1903; for many years surgeon of Keokuk & Western, and St. Louis, Keokuk & Northwestern Railways; died at his home in Keokuk, August 25, from diabetic gangrene, aged 62.

Abner Wellborn Calhoun, M.D. Jefferson Medical College, 1869; a member of the American Medical Association; pioneer oculist of the south; professor of ophthalmology and diseases of the ear, nose and throat, in the Atlantic College of Physicians and Surgeons; attending surgeon to Grady and Wesley Memorial hospitals and St. Joseph's Infirmary, Atlanta, Ga.; a Confederate veteran; died at his home in Atlanta, August 21, aged 65.

Guilford O. Bicknell, M.D. Vanderbilt University, Nashville, Tenn., 1882; a member of the American Medical Association and founder of the Munroe County Medical Society of Etowah, Tenn.; division surgeon of the Louisville & Nashville Railroad; died suddenly at a hospital in Danville, Va., August 12, aged 51.

John Wells Bulkley, M.D. Berkshire Medical College, Pittsfield, Mass., 1844; a member of the Medical Association of the District of Columbia, and senior member of the consulting staff of Providence Hospital, Washington, D. C.; died at his home, August 23, aged 86.

Francis Collamore, M.D. Dartmouth Medical School, Hanover, N. H., 1847; a member of the Massachusetts Medical Society; said to be the oldest practitioner in Plymouth county; died at his home in Pembroke, Mass., August 18, from cerebral hemorrhage, aged 84.

Elmer Erickson, M.D. College of Physicians and Surgeons, Chicago, 1909; assistant physician at the Elgin State Hospital; died at the Augustana Hospital, Chicago, August 17, from general peritonitis, following an operation for appendicitis, aged 22.

John W. Faucher, M.D. Indiana Medical College, Indianapolis, 1876; surgeon in the army during the Civil War and stationed at the General Hospital, Nashville, Tenn.; died at his home in Sheridan, Ind., August 19, from gastroenteritis, aged 71.

Jerome J. Valede, M.D. Detroit College of Medicine, 1882; a member of the Michigan State Medical Society; founder and president of the bank of Newport, Mich.; died at his home in that place, August 15, from chronic nephritis, aged 51.

Robert Thomas Bartram, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1886; a member of the Iowa State Medical Society; formerly of Albia, Iowa; died at his home in Ellsworth, Kan., August 12, from septicemia, aged 57.

John Morgan McLaughlin, M.D. University of Maryland, Baltimore, 1888; a member of the American Medical Association; of Webster Springs, W. Va.; died at a hospital in Clarksburg, W. Va., August 19, from typhoid fever, aged 50.

Herbert Marcus Goodman, M.D. Rush Medical College, 1909; an interne in Cook County Hospital; died at the home of his father in Chicago, August 19, after an operation for carcinoma of the pharynx, aged 27.

Arthur Benjamin Bevier, M.D. Bellevue Hospital Medical College, 1881; a member of the American Medical Association; died in his office in Ridgway, Pa., August 4, from cerebral hemorrhage, aged 52.

Russell Cleveland Campbell, M.D. Medico-Chirurgical College of Philadelphia, 1909; of New Germantown, Pa., is said to have committed suicide by taking cyanide of potassium, August 18, aged 24.

Clarence Lee Addleman, M.D. University of Pennsylvania, 1875; of Mammoth, Utah; a member of the State Medical Association; died in Greencastle, Pa., May 20, from narcotism, aged 67.

Dayne Hamilton Griffith, M.D. Jefferson Medical College, 1905; member of the staff of the Pittsburg, Pa., Hospital; died at North Bay, Ont., August 20, from acute gastritis, aged 26.

Emily A. Cady-Harris, M.D. Woman's Medical College of the New York Infirmary for Women and Children, 1889; died at her home in Rochester, N. Y., August 12, from diabetes, aged 49.

Henry Franz Koester, M.D. Bellevue Hospital Medical College, 1891; a member of the Medical Society of the State of New York; died at his home in New York City, July 28, aged 47.

Walter S. Graham, M.D. Hahnemann Medical College, Philadelphia, 1884; a member of the Florida Medical Association; died at his home in Miami, June 19, from tuberculosis, aged 52.

William Jefferson Easley, (license, years of practice, Ill.); formerly of Raymond, Ill.; died at the home of his daughter in Decatur, Ill., August 7, from senile debility, aged 82.

William Claude Usher, M.D. Harvard Medical School, 1908; an interne in the Boston Lying-in Hospital; was drowned in the Charles River, August 10, aged 24.

Joseph Brinton Crandall, M.D. Hahnemann Medical College, Chicago, 1878; died at his home in Clinton, Wis., July 4, from cerebral hemorrhage, aged 92.

Dana Bailey Goddard, M.D. University of Vermont, Burlington, 1899; died at his home in Brattleboro, Vt., July 22, from cerebral hemorrhage, aged 36.

George Donald Reid Simpson, M.D. University of Toronto, 1895; formerly of Hamilton, Ont.; died at his home in Toronto, April 8, aged 36.

August Hypolite Borey, M.D. Tulane University of Louisiana, 1905; died at his home in New Orleans, July 14, from appendicitis, aged 26.

Robert M. Gallen, M.D. Illinois Medical College, Chicago, 1904; died at his home in St. Louis, Mo., August 15, from diabetes, aged 34.

James A. Harris, (license, years of practice, Ill., 1878); died at his home in Carriers Mills, August 20, from heart disease, aged 74.

Walter Franklin Atlee, M.D. University of Pennsylvania, 1850; died at his home in Philadelphia, August 18, from pneumonia, aged 81.

James Brooks, M.D. Cleveland Medical College, 1844; died at his home in Ellington, N. Y., August 5, from carcinoma, aged 87.

Hiram Burton (license, Ind., 1897); died at his home near Somerville, Ind., August 17, from chronic nephritis, aged 78.

The privy is the great sanitary problem of the open country and non-sewered villages. As human carriers of bacterial and parasitic infections are not known, it is necessary to impress on the public that all human feces are dangerous. The burial of night soil without first treating it is dangerous and may result in disease. Burning or boiling human excreta is the ideal plan, but is not of universal feasibility. The surface privy is a distinct improvement over none, but is unwarranted in view of present day knowledge. The pail system is the least that can be demanded, but some safeguarding material should be used in the pail. If the dry earth system is used the privy must be made fly-proof. The advantage of the water-kerosene method is that it can be installed with so little trouble and change in present privies. Further studies are required on this system in connection with splashing and minimum time for fermentation. [The use of kerosene on night soil or on manure piles interferes with the usefulness of the material for fertilizer. Iron sulphate solution has been suggested as efficient in the destruction of fly larvæ in their breeding places, and does not prevent the use of the manure for fertilizer.—Ed.]

Some Symptoms of Intussusception.—Pain is of great severity and usually paroxysmal. Rarely is it continuous at the start, though it often becomes so during the second and third day. The pain is usually referred to the umbilicus and is most marked during the first two days. In chronic cases it is almost always absent. Vomiting is most marked at the onset, but may continue severe throughout the attack. It is not so much a symptom of intussusception as it is of acute intestinal obstruction. The vomiting is projectile and uncontrollable. At first it consists of stomach contents, but soon it becomes greenish from the presence of bile and then, if obstruction to the intestines is complete, it becomes fecal. Fecal vomiting is not common in infancy, only from 10 to 11 per cent. of children under ten years having it. It is a bad sign, though not always a fatal one, and rarely seen before the third or fourth day. Vomiting is absent in chronic cases. Bowel symptoms are prominent. Characteristic symptoms of acute intussusception are the bloody and mucous stools, present in three-fifths or more of all cases. The discharge of blood frequently follows the attacks of severe colicky pain. In some cases it is not discharged spontaneously, and only when an enema is given do we get any evidence of blood. The amount of blood passed each time varies from a mere trace in the mucus to an ounce. Constipation in acute cases is usually complete, neither gas nor feces being passed. There are usually one or two watery stools after the onset. In some cases the opening at the apex of the intussusception may not be completely closed and in these cases there is complete constipation. Tenesmus is present in one-third of the cases and especially if the tumor is in the large intestine. Tympanitic distention is seen in one-third of the cases and occurs usually on the second or third day, the abdomen being usually soft and relaxed during the first day or two. The distention is especially marked if the lower bowel is involved, whereas if the invagination is high up in the small intestines it may be so slight as to go unnoticed. In cases in which the opening at the apex of the intussusception is not entirely obliterated the distention may not be marked, even though the obstruction is in the large bowel. The tumor is one of the most diagnostic symptoms. It may be present as early as a few hours after the onset and in three-fourths of all cases it is found on the first day. —H. J. Morgenthaler, in *Am. Jour. of Obstet. and Dis. of Women and Children*.

Serodiagnosis of Syphilis in the Insane.—The thirty-first annual report of the Binghamton (N. Y.) State Hospital for the Insane in its pathologic section gives some data of interest in regard to serodiagnosis of syphilis in the insane. A series of cases was studied to determine the value of the precipitate reaction in the spinal fluid. The number of positive reactions in non-syphilitic cases was so great as to indicate that the precipitate reaction cannot be considered as specific for either paresis or syphilis. Similarly, Noguchi's butyric acid reaction was positive in so many non-paretic

cases as to be considered inconclusive, and it is stated that the small quantities of the various solutions used by Noguchi give misleading results. The Noguchi modification of the Wassermann reaction was used in about 50 cases with positive results in all the paretics and other patients with syphilitic history, while all the non-syphilitic cases gave negative reactions. In 20 cases of paresis the tuberculo-opsonic index was studied. One case showed an index above normal; 6 were normal and the average of the 20 was 0.6, which is below normal. This would indicate that paretics have no natural immunity to tuberculosis, which is contrary to the view expressed by an investigator in one of the New York hospitals last year (*THE JOURNAL*, Feb. 13, 1909). Two of the 25 deaths of paretics were due to tuberculosis.

Autotoxemia and Infection.—In a communication to the Royal Society, London, June 23 (*Nature*, June 30), E. C. Hort reported some experiments made to show that the injection of small quantities of distilled water alone would cause in small animals the phenomena of bacterial and protozoan infection, such as fever, loss of weight, and changes in the antitryptic values of the blood serum. He produced fever in rabbits and guinea-pigs by the injection of boiled distilled water, one to sixty centigrams, and by proper spacing of the injections continuous fever could be produced. Hypersensitization was frequently observed. Small single injections were not conclusive as regards loss of weight, but multiple injection always produced it. Multiple injections of simple boiled distilled water always produced marked rise in antitryptic values, strikingly parallel with those produced by diphtheria toxin or living bacteria injections in the same species of animal. From these results he draws the inference that a part, at least, of the disease-complex of infection is the result of a state of true auto-intoxication, however great may be the part played by the bacteria and protozoa. Such auto-intoxications he suggests may be in part directly due to the absorption of derivatives of the infected cells themselves and only indirectly to the absorption of bacterial products.

Neri's Sign of Organic Hemiplegia.—The *Nouvelle Iconographie*, XXIII, 1910, 88, gives an illustrated description of the sign to which V. Neri calls attention. In some cases this sign occurs alone and it may be elicited when the patient is in coma. It consists in the spontaneous bending of the knee as the leg is passively lifted, the patient in the dorsal decubitus. The sound leg can be raised to an angle of 70 degrees without the knee's flexing, while the knee of the paralyzed limb bends between 40 and 50 degrees. If the patient stands erect with folded arms and is then told to stoop forward, keeping the legs stiff, the knee flexes on the paralyzed side, while the sound knee remains stiff. This sign is not pathognomonic of organic hemiplegia but is useful to corroborate other signs.

Pertinent Questions.—Why conserve coal mines and not conserve the life of the coal miner? Why conserve the cotton plant and expend \$500,000 to fight the boll weevil and not conserve the people, who are to be clothed with the cotton? Why conserve the life of tree and fight the San José scale, and not conserve the people who eat oranges? Why conserve the life of the forest and forget the life of the forester and of his children? Why protect tree life and plant life and neglect human life? Why protect cattle from Texas fever and not protect people from typhoid and malarial fever? Why protect pigs and forget the children?—*Senator Owen, of Oklahoma*.

Sulphuric Acid Burns.—The spilling of sulphuric acid on the body or the clothes is not a very common accident, but it is well to remember that plenty of water applied immediately will prevent any harm. When spilled on clothes, sulphuric acid decomposes them so that they fall to pieces, but it should be generally known that application of water dilutes the acid and washes it away. Workmen sometimes break receptacles containing sulphuric acid, and malicious persons sometimes use it in the attempt to disfigure faces. If necessary, the hose can be turned on the affected person or he may be unceremoniously thrown into any body of water that is handy.

Dorsey's, and hosts of others now dead but great in the annals of medical discovery and service, like the laborious Duglison and others, like Paul Beck Goddard, who should be honored. Why is there not a memorial medical university, not an annex to a literary institution, but an independent exclusively medical university to Ephraim McDowell, to Nicholas Senn, to Valentine Mott and others like them, now gone to the glory of the skies, but not yet properly glorified by us here below in suitable structures of stone?

If we look for the living to memorialize there are the Mayo Brothers of Minnesota. There are Sajous, Shoemaker, and La Place of Philadelphia, to say nothing of Murphy, Finlay, Gorgas, Flexner, Ochsner, Billings, and many others among us yet in other cities and men abroad who have carved deathless names on Fame's memory tablets, and Osler, now not with us, but who worked like a trojan for Johns Hopkins.

At one time St. Louis, through its independent medical schools named after dead medical worthies, did more than any other city to keep the fame of its medical worthies alive by naming its medical colleges after them.

Why not have a renaissance of great men of medicine in memorial educational monuments to the work they did for the world's welfare, not in St. Louis and Chicago alone but in other cities and sections of the country?

Two St. Louis public schools bear the honored names of Pope and Hodgen. Why not name medical schools after them, also; and Watters, Linton, and others of that good old school? I saw John T. Hodgen in the amphitheater of the St. Louis Medical College more than thirty years ago, when he was teaching physiology there, repeat the demonstrations of Flourens on the cerebelli of pigeons and the school was then independent of Washington University, a two-year school with one previous year of home study with a preceptor its minimum requirement.

I saw practical toxicology demonstrated in such a way at the same school that I could never testify that hydrocyanic acid could take all day to kill a man as was testified to as a fact in the recent Hyde trial at Kansas City. This school had no university laboratory connection at that time either.

C. H. HUGHES, M.D., St. Louis.

Registration of Foreign Physicians

To the Editor:—I wish to express my approval of the letter on this subject in THE JOURNAL, August 6. I am a graduate of a medical school in Boston, but a South African by birth and held citizenship rights there before the war with England. Since my graduation here I endeavored to obtain the right of practicing in my own home, which has been denied me because of the laws existing in all British colonies. I have been given the privilege of taking an English degree, should I choose any of the colleges quoted by the council in London. As a means of obtaining this right, it was suggested that I go to Halifax (Nova Scotia) Medical College, where it would be easier to obtain a degree. This particular college has not received the approval of the Council on Medical Education of the American Medical Association or of the Carnegie Foundation. Nevertheless I was advised to go there by the registrar of the Medical Council of London, and to obtain a degree acceptable toward a certificate from the council in London which would enable me to practice in South Africa. Last year, in the Transvaal, after some agitation, through influential friends, a provision was made, which gave the right to the Transvaal Medical Council to grant certain privileges to South-African born students, desiring to attend and graduate from other than English medical schools.

It seems passing strange and unfair that the choice of the place of one's education should be denied to an inhabitant of a supposedly free and liberally governed country. It restricts the practice of medicine largely to the English, a great many of whom are graduates of colleges of not so good a standing as some American ones. If this information and protest will do any good to change the present state of affairs here and demand reciprocal rights, I shall be quite satisfied to remain here in my adopted country.

JAMES A. HONEIL, M.D., Cambridge, Mass.

The Whistle in the Stomach, Who Blew It First? A Question of Priority

To the Editor:—The story is different from that told by Benjamin Franklin, but the moral is strikingly similar.

Eleven or twelve years ago I was possessed by the ambition to devise a method by means of which the exact length of the esophagus might be clinically determined. While waiting for inspiration I did the customary thing—I whistled. Like Newton's discovery of the law of gravitation at seeing the apple fall, to me, likewise, came the idea while "wetting my whistle." Since my whistling at the esophagus and my whistling for the esophagus were like "whistling jigs to a milestone," why, thought I, whistling, not try to whistle into the esophagus? The result was that I did some more whistling and succeeded in hearing the sound of a whistle issuing from the innermost recesses of the abdominal viscera. To my ear it sounded like the first cry of my first-born.

I gave shape to my thoughts in a paper entitled "The Esophagometer or the Intragastric Whistle; A new Device for Measuring the Esophagus in the Living," which was read at the meeting of the Colorado State Medical Society, June 18-20, 1901, and which was subsequently published in the *New York Medical Journal*, Aug. 31, 1901.

I quote here a few lines referring to the principle on which the device is based and the description of the instrument.

My method is based on the principle of acoustics, that sound is produced by the vibrations of air, and on the facts that the stomach is a hollow organ containing air, and that the esophagus when not in the act of swallowing is an air-tight organ. Hence, a musical instrument, when introduced into the esophagus, will produce no sound whatsoever throughout the whole of its length, but so soon as it reaches the threshold of the stomach, the cardia, it will emit a sound.

My device consists of a stomach tube provided at its proximal end with a whistle. . . . The whistle is secured in the tube by tying it externally with a piece of catgut or silk. The tube is introduced into the esophagus, and air blown in by means of a pump, Davidson syringe, Politzer bag, the mouth, or what not. So long as the whistle traverses the esophagus the instrument is smothered and no sound is heard; but, so soon as the cardia is reached a distinct whistle is heard. The tube can be pushed forward and backward several times so as to ascertain the exact point at which the whistle becomes audible. The distance between the distal border of the side opening of the tube and the point at the incisor teeth where the whistling sound is first heard represents with precision the distance between the incisor teeth and the cardia.

An illustration of the instrument accompanied the article.

All these years I have been nursing the belief that I am the only and original whistler who first blew a note into the expanse of the stomach, and that to the end of time wherever the muffled sound of the intragastric whistle would be heard, there also the sound of my name would be echoed. But alas, my dream of fame and immortality is now hanging in the balance. There is another man who clamors for the honor and claims the first gastric blast.

Dr. Robert Coleman Kemp, in his treatise on "Diseases of the Stomach and Intestines" (Saunders, Philadelphia, 1910) gives a description and illustration of a stomach whistle which is identical with mine of 1901 vintage. Under the illustration is to be found the modest legend: "Kemp's Stomach Whistle."

The question at issue is: Who of us two whistled first into the stomach, and whether in the subsequent editions of Kemp's excellent treatise the legend under the illustration should be retained or changed.

I paid in full for Dr. Kemp's book and thought it was fully worth the price until I found there the story of the whistle, the moral of which, until proof to the contrary be forthcoming, is that I paid too much for my whistle.

C. D. SPIVAK, M.D. Denver.

[A proof of the above letter was submitted to Dr. Kemp, who replies:]

To the Editor:—Though I exercised considerable care during the preparation of my recent work on "Diseases of the Stomach and Intestines," especially in properly crediting other authors and their investigations, I must frankly confess that I had not seen Dr. Spivak's article or known of its

Pharmacology

HYDRONAPHTHOL

A correspondent having requested information regarding the composition of "Hydronaphthol," the product was investigated in the Association laboratory. The laboratory reports as follows:

Hydronaphthol is sold by Seabury & Johnson. The label on a trade package of Hydronaphthol gives no clew as to the nature of the product. The statements on the labels do, however, make the claim that Hydronaphthol is an antiseptic of great power, also that it is non-toxic and therefore may be used with impunity; thus the following statements are made:

"A harmless, practically odorless, non-poisonous, non-corrosive antiseptic . . ."
". . . It is non-poisonous and can be employed with perfect impunity as a preservative . . ."

The substance has the characteristic appearance, odor and taste of naphthol. It responded to all the tests of the United States Pharmacopeia for betanaphthol, with the exception of the melting point, which was found to be 119 C. instead of 122 C., an indication of impurity. It is evident, therefore, that Hydronaphthol is merely a trade-name for betanaphthol. While resublimed betanaphthol is listed at 10 cents an ounce, Hydronaphthol is listed at 75 cents an ounce.

Hydronaphthol thus furnishes one more illustration of the fact that most proprietary medicines for which the most extravagant claims are made are but old and well-known remedies sold under a fancy name at a price far in advance of that charged for the constituent or constituents. The exploiters are extremely positive in their statements regarding the non-toxic character of the preparation. Yet, as a matter of fact, betanaphthol is by no means harmless; it has been absorbed by the diseased skin with injury to the kidney and with fatal results. In some cases injury to the eye has also occurred. These toxic actions should be known to the practitioner. From 3 to 4 gm. (1 dram) applied to the skin has produced death (Stern: *Therap. Monatshefte*, 1900, p. 165.) When a manufacturer advertises a preparation which possesses potentialities for harm, and especially when he puts it out under a name which conceals its identity, it is incumbent on him to warn the customer of possible injurious or inconvenient actions instead of proclaiming that the preparation is harmless.

PROPRIETARIES IN ITALY

The general discontent with the way in which proprietary medicines are being advertised in Italy is voiced by Dr. A. Zambler, in a communication in the *Gazzetta degli Ospedali*. He states that Dr. Silingardi has recently prepared a brief on the subject to call the attention of legislators to it. The subject is one, Zambler remarks, which while of great interest to the medical profession is of far greater interest to the sick and suffering public. The public authorities, he continues, can no longer close their eyes to the matter as the advertising propaganda has become so incessant and pervading. He says that the third edition of the Italian Pharmacopeia includes a notable display of proprietaries and it is the only Pharmacopeia thus distinguished. He does not comment on their value but only remarks that their inclusion in the Pharmacopeia is an effective form of official advertising in favor of the richer manufacturing firms.

He suggests that the authorities should forbid the sale of all proprietaries that fail to obtain a certificate from the national board of health as to their therapeutic value. Zambler comments that the means to dispel the evil are within reach. All that is necessary, he states, is for physicians to agree on the matter, and for the authorities to have the good of the public in view rather than the good of commercial private interests, and to have the present sanitary regulations more strictly enforced.

Correspondence

Wanted: Specimens of Nervous System From Fatal Cases of Poliomyelitis

To the Editor:—I should be greatly indebted to you for any assistance that you could render me through the columns of THE JOURNAL in enabling us to secure specimens of the nervous systems from fatal cases of epidemic poliomyelitis, a disease which is widely prevalent throughout the United States and Canada at present. We should like to obtain portions of the spinal cord and, by preference, of the lumbar or cervical enlargement removed as soon after death as possible, and preserved in plenty of pure glycerin, Squibb's or Merck's or Kahlbaum's. These specimens are to be used for experimental purposes; they can be sent by express at our expense, or by mail addressed to me at the Rockefeller Institute, Sixty-sixth Street and Avenue A, New York City.

SIMON FLEXNER.

Anglo-American Medical Association of Berlin Employs Permanent Secretary

To the Editor:—For the benefit of those who wish to do medical work in Berlin, the Anglo-American Medical Association has employed a permanent secretary who, on request, will furnish information concerning the medical courses obtainable here, the approximate cost, etc. Letters should be addressed to the secretary of the Anglo-American Medical Association, 105 B Friedrichstrasse, Berlin, Germany.

H. O. BRUGGEMAN, President, Berlin.

Obliterating the Monuments

To the Editor:—To one who has yet a pride in the achievements of American medicine and in the glory of its great names, it is painful to see pass out the educational monuments that kept in professional memory the great men of American medicine and memorialized them before the public.

If medical colleges are to become only annexes of great literary and scientific endowed universities it is not necessary, nor is it kind, that the honored, worthy and great medical names they represent in many instances, and in others have borne, should be obliterated and lost to the rising generation and to posterity. The profession reveres the names yet and none need be ashamed of them though men who love them then wrought in or founded only two-year schools (may be), where such physics and biologic results only were taught as the students of medicine must needs then have had and anatomy was demonstrated when most of the world was asleep, and when conditions and demands of study were not as they are now.

Chicago still honors the name of Rush. May it never cease to keep that honored American name, the first among the great psychiatrists, though few schools are yet teaching psychiatry. But what school bears the honored name of N. S. Davis? What school has ever honored Dudley of Kentucky? And where is the name of Marion-Sims, borne by a once meritorious medical school of St. Louis, rejoicing in this great name and in medical independence? Merged and silenced into an annex to another institution, the Catholic St. Louis University and the Beaumont.

And where are the Charles A. Pope School of Medicine and the Joseph N. McDonnell school? Likewise merged and lost in another university, the Washington University of St. Louis; and where is the "Humboldt-Hammer" school? Passed into the College of Physicians and Surgeons of St. Louis and the new regular changed from eclectic simply bears the name "American." Why should it not have been rechristened with an eminent American medical name? It would be well for the profession to have a care for its own if it would have them justly esteemed by others.

There are the names of Holmes, Parker, Bowditch, and others of Boston. There are the Brown-Sequards, the Drapers,

tions from such a small number could not be of much value. This holds with reference to the vast majority of affections. In cancer about 1,600 cases are recorded, and in sarcoma 300, including all the different varieties. Here the figures may be of more value. The finding in this series of cases of carcinoma is that between 50 and 60 is the period of greatest frequency, and in regard to sarcoma that there is practically no difference between the decennial periods. Ovarian affections are found most frequently between 20 and 30. Other findings do not differ materially from those already stated. A brief definition is given of each disease, and some general deductions are made aside from the figures. The book will be of interest for reference by workers in any particular disease or branch of medicine.

THE DEVELOPMENT OF PUBLIC CHARITIES AND CORRECTION IN THE STATE OF INDIANA. Paper. Pp. 132, with illustrations. Indianapolis: Board of State Charities, State House, 1792-1910.

Indiana is recognized as being well in the forefront of the states in the conduct of its penal, correctional, and eleemosynary institutions. This pamphlet of 132 pages on the history, development, aims, and purposes, together with statistics of the work of the seventeen charitable and correctional institutions in the state, makes an interesting document. Each of the institutions is described and illustrated with half-tone pictures, the plans of many of the institutions being given. A history of the legislation creating each one, its purpose and the manner of conducting it, is given, and the results of child-saving work, of the truancy law, the indeterminate sentence law, county and township charities, the work among the insane, the epileptic and the feeble-minded, are all set out in statistical and graphic manner. The pamphlet has a table of contents and an index and is an interesting contribution to sociologic work.

TWENTY-FIRST ANNUAL REPORT OF THE DIRECTOR OF THE PSYCHIATRIC INSTITUTE, 1908-1909. To the State Commission in Lunacy, State of New York [Adolf Meyer, Director, Pathological Institute, Ward's Island, New York]. Paper. Pp. 131. 1910.

This report gives a synopsis of the courses of instruction and observation laid out at the Psychiatric Institute for the benefit of the physicians of the other state institutions, covering periods of one week to three months. It also describes the efforts to establish standards so that the information might be used for statistical purposes, and gives a report of the clinical work, with descriptions or histories of cases of the various clinical classifications, the histologic findings in the brain and cord of those cases available for such examination, whose histories are given, and of other specimens sent for examination from other states, with an analysis of the cases by groups and subgroups. The whole report makes an interesting and valuable study for reference by the alienist or psychiatrist.

MONOGRAPHS ON MEDICAL AND ALLIED SUBJECTS. Published by the Rockefeller Institute for Medical Research. No. 1. Issued June 30, 1910. Paper. Pp. 130, with illustrations. New York: 66th St. and Ave. A, 1910.

This is the first of a series of monographs on medical and allied subjects to be issued at irregular intervals by Rockefeller Institute for Medical Research. It contains five papers, profusely illustrated with microphotographs and other plates, one of them colored. Some of the papers are on tumors and experiments by Flexner and Jobling in transplanting tumors in the rat, mouse, and monkey; and one is on some experiments by Maud L. Menten with radium bromid on carcinoma in the rat. The whole representing work done in the Rockefeller Institute.

CONGENITAL DISLOCATION OF THE HIP. By J. Jackson Clarke, F.R.C.S., Senior Surgeon to the Hampstead and North-West London Hospital. Cloth. Price. \$1.50 net. Pp. 92, with 55 illustrations. New York: Paul B. Hoeber, 69 East 59th St., 1910.

The author began his work in 1903 after Lorenz's visit to London, and he reports 40 cases. Except for the report of these cases the book contains little that might not have been heard and observed at a clinical lecture by Lorenz eight years ago, with such additions as a surgeon, who had operated on only a few cases and had not yet "found himself," might be expected to set down when writing a book. In a word the book contains nothing new of any value and much that is ancient, unnecessary and misleading.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Economic Value of Health.

In the twenty-first annual report of the State Board of Health of Florida, the president of the board in his letter of transmissal to the governor emphasizes the value of the State Board of Health and its work to the people of the state, as a business asset. The contrast between present and previous conditions is admirably drawn. The fact that the president of the board is a layman adds interest to the letter.

"It is a well known fact that prior to the great epidemic of yellow fever in 1888 the increase in the state's population from immigration was almost inappreciable compared with the gain since the period mentioned. It is within the memory of even our younger people that as each summer came there was talk of yellow fever, its probability of occurrence and the point where it would first make its appearance. This periodic agitation of a subject which vitally interested not only the physical life of the citizen, but his business existence as well, brought about conditions which yearly disturbed home comfort and retarded the coming of people into the state, besides restricting the investment of capital, so necessary to develop many important industries and avenues of commerce which held out flattering returns. People were scared, and naturally so in placing their money where health conditions were so uncertain and where an epidemic of yellow fever depressed values to a degree that it would take years of exemption to recover from. Then again, the diversity of opinion as to management when disasters of this character did occur and the inconvenience and annoyance to travel and commerce which arose on each county line, demoralized both the citizen and business, so that, at almost every path and by-road in the state, the traveller, whether from an infected portion of the state or not, was harassed by guards, who in the majority of instances were ignorant of the essential requirements of their positions, and who rendered really no practical service in restricting the spread of a contagion, but did inflict, by their orders and insistence on them, many indignities on women and children, and, in several instances, serious impairment to health.

"Compare the conditions existing in the state in 1888 with an epidemic of yellow fever in Jacksonville, and the conditions which prevailed in 1905 with an epidemic of the same disease in Pensacola, Fla. In the former instance, panic prevailed; every man's hand was raised against his neighbor of adjoining counties, under a false supposition of protection against an unseen enemy; commerce was strangled and stagnation of business consequently followed. In 1905—in the latter instance—without a ten-mile area around Pensacola, travel within the state was undisturbed. Business followed its usual methods and there was no panic, no excitement, no hysteria of even those most skeptical of the ability of the State Board of Health to cope with the situation and confine the disease to one point in the state, where it had unfortunately gained entrance, which occurred, however, through no lack of careful supervision or attention. Even when a case of yellow fever occurred in Tampa by direct importation from New Orleans, at a period in the history of that epidemic when the disease was not known to exist in New Orleans, there was no uneasiness felt at Tampa, and there was not for one minute a suspension of travel or commercial relations with the other portions of the state....

"Is it unreasonable, therefore, to argue or to maintain that the part played in the wonderful development of Florida since 1888 has been due very largely to a confidence in the safety of living in the state, which confidence has been inspired by the work which the State Board of Health has done along health lines and which it is still earnestly engaged in? Would people come to the state from the west, northwest, northeast, and middle west, buy property, institute new industries, and settle permanently among us, if they did not feel that their lives were being guarded against disease, and their accumulations of property interests were being protected against needless fright and senseless panic? I do not say nor pretend to assert that the State Board of Health has been the only factor in the strides which Florida has made towards financial development in the past twenty years, but I do maintain without fear of successful contradiction, that the board has contributed a large share to the success which the state now

enjoys, and it will be recognized in the future, if not already so considered, as an investment on the part of the people which should be allowed the greatest latitude of administration."

“Antivivisection Mush”

A recent criticism of the Bureau of Animal Industry at Washington is commented on as follows by the Natchez (Miss.) News, under the above heading:

“Sentimental antivivisectionists of Washington are raising a howl because they have discovered that the Bureau of Animal Industry and other government institutions in the capital have done some vivisection work on dogs and threaten prosecution; they also threaten to have a law passed prohibiting vivisection under any circumstances in the District of Columbia, it being permissible now for medical or scientific purposes. The great trouble with many self styled reformers is that they make themselves ridiculous. Whoever will make the least effort can learn that much of the progress of modern medicine and biologic science is due to vivisection; some of the most important discoveries are due to wilful destruction of lower life.

“Theoretically, the humblest insect is entitled to life and the pursuit of happiness as the greatest human genius; but it must be carefully remembered that man has reached his high stage only on account of his fitness to survive, and on account of the fact that to gain his own ends he regards all other forms of life as subservient to his purpose. Animals are killed for their flesh and vivisection is practiced because in that manner only can many processes of life, of health or of disease, be determined. That unnecessary cruelty should be forbidden is admitted by all, but from the human point of view there is no cruelty in vivisection, if by practicing it on a dog or on a guinea-pig, something of importance can be learned. And a new discovery is of the utmost importance, whether its applicability be immediate or in the distant future. Every scientific discovery sooner or later will demonstrate its utility to mankind. From a purely doctrinal point of view it is cruelty to the dog to submit him to vivisection, but his feelings in the matter should be consulted no more than the feelings of animals are consulted when they are slaughtered for food.

“Such reformers as the antivivisectionists can find much suffering among human beings to exercise their kindness and charity on. Even in civilized countries human beings suffer pain, hunger, humiliation and other misfortunes that cry for relief and for whom relief could be found; nearly all the suffering caused in vivisection is caused for the benefit of mankind, and man is and should be the first consideration of man.”

State Boards of Registration

COMING EXAMINATIONS

IOWA: Capitol Building, Des Moines, September 12-14. Sec., Dr. Guilford H. Sumner, State House.
MASSACHUSETTS: State House, Boston, September 13-15. Sec., Dr. Edwin B. Harvey.
MISSOURI: Capitol Building, Jefferson City, September 20-22. Sec., Dr. Frank B. Miller.
NEW YORK: Albany, September 27-30. Chief of Examinations Division, Dr. Charles F. Wheelock.

Georgia May Reports

Dr. I. H. Goss, secretary of the Georgia Board of Medical Examiners, reports the written examinations held at Atlanta, May 4-7 and at Augusta, May 2-3, 1910. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 80.
At the examination held at Atlanta, the total number of candidates examined was 113 of whom 108 passed and 5 failed. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
Howard University		(1909)	84.
Atlanta College of Physicians and Surgeons		(1910)	80, 81, 81.5, 82, 82.5, 83, 83, 84, 84, 84, 84, 84.5, 85, 85, 85.5, 85.5, 86, 86, 86, 86, 86.5, 87, 87, 87.5, 87.5, 87.5, 88, 88,

88, 88, 88, 88, 88, 88, 88, 88, 88.5, 88.5, 89, 89, 89.5, 89.5, 90.5, 91, 92.5, 95, 95.5.		
Atlanta School of Medicine, (1910)	80, 82, 83.5, 84, 84, 84, 84, 84, 85, 85, 85, 85, 85.5, 85.5, 86, 86, 86, 86, 87, 87, 87, 87, 87, 88.5, 89, 90, 90, 90, 91, 91, 91, 91.5, 92.5, 95.	
Albany Medical College	(1899)	93.5
Leonard School of Medicine	(1908)	81.5
University of Tennessee	(1908) 86; (1910)	92.
University of the South	(1909)	83.
Meharry Medical College (1906)	82; (1908) 85, 87; (1910) 80, 81, 83, 83, 85.5, 86, 86, 89, 89.5, 89.5.	
Medical College of Virginia	(1869)	87.

FAILED

Leonard School of Medicine	(1905)	76.
Chattanooga Medical College	(1910)	78.
Meharry Medical College	(1910)	77, 79.
Knoxville Medical College	(1908)	74.5

At the examination held at Augusta, the total number of candidates examined was 14 all of whom passed. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
University of Georgia, (1910)	84, 84.5, 84.5, 85, 86.5, 86.5, 87, 87.5, 88, 90, 90.5, 92, 92.		
Medical College of South Carolina	(1906)		88.

LICENSED THROUGH RECIPROCITY SINCE MAY 1, 1910

College.	Year Grad.	Reciprocity with.
University of Missouri	(1895)	Virginia
University of Pennsylvania	(1887)	Florida
Memphis Hospital Medical College	(1910)	Tennessee
University of Nashville	(1908) (1910)	Tennessee
Meharry Medical College	(1909) (1910)	Tennessee
University of Virginia	(1907)	Virginia

The following questions were asked:

ANATOMY

1. Name bones of tarsus. What bones form internal malleolus? External? What bones comprise the pelvis? Name divisions of vertebral column, and give distinguishing characteristics of cervical vertebra. 2. What muscles aid in mastication? In deglutition? Give origin, nerve and arterial supply of masseter muscles. What muscles compose quadriceps extensor femoris? Give origin and insertion of quadriceps extensor femoris. 3. Name divisions of alimentary canal. Name principal glands found in small intestine. What is average size of stomach? Give blood supply. Name abdominal viscera wholly covered by peritonium? Partially covered? 4. Name and illustrate by diagram the regions of abdomen; where in the topography of abdomen is vermiform appendix. Describe briefly Poupart's ligament. 5. Give origin of left common carotid artery. Name branches of left external carotid. Name twelve pair nerves of special sense. Give origin and cranial exit of pneumogastric nerve. Name the three most important branches.

PHYSIOLOGY

1. Define reflex action and give example. 2. Describe the functions of the kidneys. 3. Give the normal constituents of the urine. 4. What is meant by digestion? 5. Name the secretions of the alimentary canal, their reactions and functions.

CHEMISTRY

1. Give test for albumin and sugar in urine. 2. Describe chemical test for blood. 3. Is organic material admixed to water always deleterious, and when is it? 4. Define an alkaloid, and name three principal ones used in medicine. 5. How are solutions, suspected to contain arsenic, to be tested?

MATERIA MEDICA AND THERAPEUTICS

1. Ergot: Its physiologic action. Its principal uses. 2. Cocain hydrochlorid: Its physiologic action. Its principal uses. 3. Chloroform: Define it. When is it indicated as an anesthetic? 4. Ether: Define it. State the conditions that render it preferable as anesthetic. 5. Define a mydriatic, also a myotic. Give examples of each with dose for local application in each case.

PRACTICE OF MEDICINE

Influenza: Definition. Etiology. Bacteriology. Symptoms. Types of the disease: 1. Respiratory. 2. Nervous form. 3. Gastro-intestinal form. 4. Febrile form. Diagnosis. Treatment. Jaundice: Definition: 1. Obstructive jaundice, causes of. General symptoms of obstructive jaundice. 2. Toxicemic jaundice. Causes. Treatment in each group. Leukocytosis: In what diseases does it occur and in what diseases is it absent. Appendicitis: Give the symptoms of. Colic: Renal and hepatic, make a differential diagnosis between.

SURGERY

1. Define abscess? Aneurism? With what condition may aneurism be confounded? Make briefly a diagnosis of coma from injury, apoplexy, uremia, opium poisoning, and alcoholic intoxication. 2. Define peritonitis. State two or more ways in which the peritoneum may be invaded by bacteria. What are the contraindications?

tions respectively to the use of the three principal anesthetics—nitrous oxid, ether, chloroform. 3. What is dislocation? Fracture? Give differential diagnosis between fracture and dislocation. Describe Colles' fracture. Outline treatment of same. 4. What is hemorrhage? How would you arrest epistaxis. Describe operation for ligation of subclavian artery in its third portion. What arteries require ligating in amputation, at middle third of leg? 5. Describe complete indirect inguinal hernia. Give symptoms of strangulation, methods of reduction, and operation if strangulation exists. Describe an approved operation for the radical cure of oblique inguinal hernia.

GYNECOLOGY

1. Give causes and treatment of uterine hemorrhage. 2. Under what conditions would you prefer vaginal to abdominal hysterectomy. 3. Describe technic of vaginal hysterectomy. 4. Give differential diagnosis between fluids in abdominal cavity and ovarian cysts. 5. Describe ectopic pregnancy, varieties, and operation for same.

OBSTETRICS

1. Would the coincidence of diabetes with pregnancy have a harmful effect on the latter? What would you do for such patient? 2. Give treatment of a subinvolved uterus. 3. Differentiate between puerperal and true puerperal infection and give treatment of each. 4. How would you distinguish between an epileptic and an eclamptic convulsion? 5. What are the indications for the use of forceps?

PATHOLOGY

1. Give the pathology in simple lobar pneumonia. 2. Give the pathology of pellagra with etiology. 3. Give the pathology in hookworm disease. 4. Describe the pathologic conditions in meningitis. 5. (a) How is fibrous tissue formed? (b) What tumors are composed largely of fibrous tissue, and in what part of the body do they usually occur?

Kansas June Report

Dr. F. P. Hatfield, former secretary of the Kansas Board of Medical Registration and Examination, reports the written examination held at Kansas City, June 14-16, 1910. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 65 of whom 54 passed and 11 failed. Twenty-three reciprocal licenses have been issued since January 1, 1910. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
Howard University, Washington, D. C.....	(1907)	81.

Patient May Not Testify in Injury Case to What Physicians Told Him, But May Describe Tests and Treatment to Recover Damages for Pain Caused by Same—Duty of Injured Person

The Court of Appeals of Kentucky says, in *Louisville & Nashville Railroad Co. vs. Lynch* (126 S. W. R., 362), a personal injury case brought by the latter party, that it was violative of one of the fundamental principles or rules governing the introduction of evidence to permit the plaintiff to testify as to what his physicians had told him. If he wanted the benefit of their testimony, he was entitled to have it either in the shape of direct evidence, given by the physicians before the jury, or he might have taken their depositions. By pursuing either of these methods he could have obtained the benefit of the physicians' investigation of his case and their testimony as to the nature and extent of his injury; but in no event was he entitled to have given to the jury, as substantive evidence, what the physicians said to him relative thereto.

While, however, it was not proper for the plaintiff to testify to what the physicians told him concerning his case, he would necessarily have to describe somewhat in detail the various tests to which he was subjected by them in their efforts to determine the extent of his injury and the probable chance of his recovery, and if this treatment or examination, made necessary in order to enable them to intelligently treat him, caused him pain and suffering, the court sees no good reason why he might not have the jury consider this as going to make up a part of the pain and suffering caused by the injury. If, through the negligence of the defendant railroad company, he was injured, then he was entitled to recover for all pain and suffering which he endured as the direct and proximate result of such injury; and, so long as the physicians employed possessed that degree of skill and proficiency in their profession usually possessed by the average practitioners in their locality, the defendant company, if primary liable, was answerable for any pain and suffering produced by them in their efforts to locate the injury and the extent thereof, even though the methods employed were not the most approved or the tests applied not the latest. He must use all reasonable means to effect his recovery, and must submit to such examination as was necessary to enable his physicians to locate the trouble and know how to treat it; and, as any pain produced by this examination was directly traceable to the negligence through the injury, it could not be dissociated from it. It not infrequently happens that the negligent or wrongful act producing the injury is followed by no immediate pain or suffering; but the treatment of the injury is attended with great pain, as in the case of gunshot wounds. When shot, the victim feels only a slight stinging sensation; but when the surgeon probes the wound to ascertain the course of the bullet, in order to determine what to do, great pain is frequently produced, all of which is directly traceable to the wrongful or negligent act—the shooting. Of course, the defendant would not be liable for suffering produced by the tortious or wrongful act of a physician not engaged in an honest effort to ascertain the seat of the patient's trouble with a view of bettering his condition if possible.

The court concludes that it was entirely proper for the plaintiff to describe the various treatments to which he was subjected so far as it was necessary for him to do so in order to properly bring before the jury the effects of such treatment on him, as to producing pain, etc. Beyond this he should not be permitted to testify concerning the treatment, but the minute descriptions of the various tests to which he was subjected and the treatment which he underwent must be left to the physicians who applied and administered same. They might go into detail in order to demonstrate, if possible, to the jury, the nature and extent of the plaintiff's injury, and the possibility or probability of his recovery.

Cases in which it was simply held that the defendant was not liable for any tortious or wrongful act of the physician where it had exercised reasonable care to select one of average skill and ability in his profession did not militate against

the position taken in this case that, the pain and suffering produced being only such as naturally flowed from the treatment regarded as necessary, it was proper for the jury to consider same.

When Ordering of Physical Examination is not Authorized

The First Appellate Division of the Supreme Court of New York says that the case, *Smyth vs. Lichtenstein* (122 N. Y. S., 74), was brought to recover damages for alleged indignities and assault, and that the burden of the complaint consisted of the indignities to which the plaintiff alleged she was subjected. The defendant procured an order of court requiring the plaintiff to submit to a physical examination as an adverse witness. No necessity for a physical examination was shown. It was apparent from the moving papers that the purpose of the defendant was, not to obtain evidence of the physical injuries alleged to have been suffered as the result of his assault, but to inquire into the previous history and physical condition of the plaintiff. If an examination for such purpose could ever be permitted, the affidavits on which it was asked were insufficient in this case. The order for the examination in this case did not come fairly within the intent of section 273 of the New York Code of Civil Procedure, which provides that in actions to recover damages for personal injuries the defendant is entitled to an order requiring the plaintiff to submit to a physical examination by one or more physicians or surgeons to be designated by the court or judge, where the defendant shall present to the court or judge satisfactory evidence that he is ignorant of the nature and extent of the injuries complained of. But a dissenting opinion of two members of the court suggests that a court has no right to refuse to enforce this mandatory provision because it thinks that the purpose of the defendant is not to obtain evidence of physical injuries alleged to have been suffered as the result of an assault, but to inquire into the previous history and physical condition of the plaintiff.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York

August 20

- 1 *The Influence of the Use of the Automobile on the Upper Air Passages. D. B. Delevan, New York.
- 2 First Aid to the Insane, and Psychopathic Wards. A. W. Ferris, New York.
- 3 *Is Mercury A Specific in Pulmonary Tuberculosis? W. N. Beggs, Denver.
- 4 Hyperchlorhydria and Abdominal and Pelvic Surgery. J. H. Carstens, Detroit.
- 5 *Is Koch's Bacillus the Cause of Cancer? T. G. McConkey, San Francisco.
- 6 The Pathology of Multiple Adenomata of the Rectum. J. M. Lynch, New York.

1. Influence of the Use of the Automobile on the Upper Air Passages.—Delevan claims that theoretically respiratory diseases should be much increased by motoring, but that practically they are not. However, acute catarrhal states of the ears and air passages and advanced tuberculosis with fever, should contraindicate motoring, which properly used in suitable cases is a valuable therapeutic agent. We need good roads, well-paved streets free from dust, and enforcement of laws against smoke and fumes, such as are found in all European cities.

3. Mercury in Tuberculosis.—Beggs does not consider mercury a specific for pulmonary tuberculosis. It is valuable in certain cases, especially when there has been a specific taint. In most cases improvement is subjective, with very slow improvement in the physical signs. When syphilis is not present, he believes that its value is due to the tonic effects of the drug, its beneficial effect on digestion or the psychic effect of the treatment.

5. Koch's Bacillus Cause of Cancer.—McConkey states his belief that the tubercle bacillus is the cause of cancer. It causes normal tissue cells to take on the habit of proliferation, and supplies the missing factor in the etiology of cancer. In the young or robust this cell proliferation is checked

by the defensive reaction of the body, and the tubercle is formed by encapsulation. But if the defense reaction is delayed or prevented, as in later life, encapsulation not taking place, the proliferation of cells goes on to the formation of a new growth. The habit of growth in the cells replaces the habit of work.

- 14 Vitiligo with a History of Heredity. E. H. Marsh, Brooklyn.
- 15 Dioxidu-amido-arsenobenzol or "606;" Ehrlich's Newest Remedy for Syphilis. S. J. Meltzer, New York.

9. Achylia Gastrica.—In Barnes' opinion, the so-called primary form of atrophy or achylia gastrica cannot be idiopathic, inherited, congenital or result from a congenital predisposition. He believes that achylia gastrica is caused by a lesion of the secretory axons of the vagus nerves, a theory which best explains, he thinks, all the chemical and microscopic conditions and all the symptoms of the disease.

10. Blood-Pressure and Urinalyses in Chronic Nephritis.—The objects of Mills' paper are: To call attention to the frequency and importance of the relationship existing between urea elimination and blood-pressure; to urge the more frequent microscopic examination of the urine in the absence of albumin; to make the urea estimation a regular procedure in urinalyses; to urge the more universal employment of the blood-pressure test in the diagnosis and treatment of disease, especially the various toxemias; to stimulate comparative studies with the view and in the hope that, on being able to determine the real value of the blood-pressure test, both singly and relatively, we may thus secure an aid to the earlier diagnosis of conditions present than would be possible by the most careful physical examination and urinalysis.

- 16 The Experimental Basis for Vaccine Therapy. T. Smith, Boston.
- 17 *Importance of Determining the Potency of Digitalis Preparations. J. H. Pratt, Boston.
- 18 *The Therapeutic Use of Ascitic Fluid: A Preliminary Communication. T. Leary, and R. W. Hastings, Boston.
- 19 Medical Social Service. W. R. Woodbury, Boston.
- 20 The Meteorologic and Hygienic Aspects of the Floods in France in 1910. G. Hinsdale, Hot Springs, Va.

17. Digitalis Preparations.—Pratt examined many specimens of digitalis—both leaves and powder—and found that most of them, at least the leaves, were only slightly active or inert. He advises that only the powder, carefully tested, be used, as that is the form in which the drug retains the greatest physiologic activity.

18. Therapeutic Use of Ascitic Fluid.—Leary and Hastings state that they have had excellent results in the treatment of intractable cases of marasmus in infants by means of ascitic fluid, one ounce being injected daily for a period of varying duration. Twelve such cases are reported.

- 50 *Experimental Conditions of Low Blood-Pressure of Non-Traumatic Origin. R. M. Pearce and A. B. Eisenbrey, New York.

43. Control of Typhoid.—The modification of Hess' medium employed by Stokes and Hachtel consists in the addition of 6 instead of 4.5 gm. of agar, and also adding 1 per cent. of lactose and 5 per cent. of glycerin. The larger quantity of agar is added, since glycerin always increases the fluidity of a medium. A most important point is to color the medium by means of a 1 per cent. solution of azolitmin powder dissolved in boiling water after the reaction has been corrected to the neutral point. This medium is then used as a plate culture for water, feces, oysters, blood-cultures and urine. In plating out stools and urine, much time is saved, as the *B. alkaligenes* forms a typical blue colony, while that of *B. typhosus* is red. Both of these colonies show the typical concentric zone. The colon bacillus is almost always small, concentrated, and forms a superficial moist red colony which bears no resemblance whatever to the much larger, spreading typhoid colony.

44. Infantilism in Uncinariasis.—Lemann reports in detail the exact study of the grade of development in a case of hookworm disease and, by contrasting it with other types of infantilism, endeavors to fix its classification. He says that the infantilism of uncinariasis has much in common with infantilism from certain other causes. On the other hand, there are some forms of arrested development with which it stands in strong contrast and with which it is likely to be confused. Such types are, for example, the achondroplastic dwarf, the mongolian idiot, the rachitic dwarf. From the achondroplastic dwarf Lemann's patient is readily distinguished by the absence of the characteristic lack of proportion between the lengths of the extremities and that of the trunk. Besides, there is no trident hand, no bowing of the long bones, no decentralization of the umbilicus, no prognathism, as there usually is in achondroplasia. The genitalia share in the retardation, while in achondroplasia they correspond in size and development to the true stage of the individual. The skiagraphs of the hookworm dwarf show none of the cartilage changes in the achondroplastic.

The hookworm dwarf has equally as little in common with the rachitic dwarf. In rickets the bone shadow is paler than normal and the medullary canal is larger, making the cancellous tissue smaller. Hence, there is a bending and bowing of the long bones. The ends of the long bones are enlarged and there is irregular cartilaginous development of the epiphyses. In addition, there is an unduly large skull, squared

and frequently "bossed." None of these features are present in the hookworm dwarf. But there is a masked cretin, the dysthyroid or hypothyroid infantile (type Brissaud) who may have had a much closer resemblance to the hookworm patient, Lemann says. In both there is a simple retardation of the development in general, involving not only the skeleton, but the genitals and the secondary sexual characteristics; in both there may be a dry skin with dry, harsh, scanty hair. But even the masked cretin, fairly intelligent, though he may be, has usually enough of the characteristics of the cretin, namely, the round full face with the thick lips, small nose and the thick skin, to distinguish him from the patient of the type described by Lemann.

45. Bones and Joints in Leprosy.—The material reported by Harbitz was obtained from patients who had suffered from leprosy for from 15 to 67 years, during most of which time they had been under observation in leprosy hospitals. There is an atrophy of the bones of the hands and feet which may proceed to such a degree that certain bones finally entirely disappear. The atrophy principally affects the most distal bones, the phalanges, metacarpals and metatarsals; it is little pronounced in the tarsus and carpus. The bones may atrophy in their entirety, though sometimes more so in the shaft, and become thin and brittle, but their shape is preserved. This variety resembles the so-called atrophy of disuse, though the bones, generally, are somewhat decreased in size. In the more characteristic form, the atrophy is concentric and chiefly involves the most peripheral parts of the phalanges, metacarpal and metatarsal bones. The distal heads of the metacarpal and metatarsal bones usually disappear, while at their base the bones preserve their usual width and thickness. The surface is generally smooth. The shortening of the metacarpal and metatarsal bones may be very considerable and most pronounced either in those on the outside or those on the inside. It may be so marked that the length is only half the normal one, or even less. The phalanges atrophy in a similar manner, and become very thin, pointed anteriorly and porous. Finally, only disconnected remnants are left, which ultimately may be entirely absorbed so that the toes become shapeless lumps without any bony framework.

In the joints various changes are also seen, on the whole, resembling those of arthritis deformans. Especially in the joints of the tarsus there is a form of chronic inflammation of the joint capsules with the picture of pronounced proliferating synovitis and serous effusion; at the same time, the articular ends show changes, such as atrophy of cartilage and bone, or proliferative alterations in the form of nodular projections, osteophytes, etc. The osseous substance, as a whole, in most cases, is the seat of marked osteoporosis. The tarsal bones become brittle and often are squeezed together to form thin plates of bone. Similar signs of chronic joint disease are seen in atrophic, leprosy hands, but less frequently and less prominently. The question arises whether this peculiar bone atrophy is specific, and directly due to leprosy neuritis, or if it can be satisfactorily explained in some other manner. Harbitz believes that there is no good reason for doubting that this bone atrophy is really of neuropathic origin, and thinks that everything seems to point to leprosy interstitial neuritis as the cause.

47. Hodgkin's Disease and Certain Allied Conditions.—The review of the clinical histories of a number of cases lead Karsner to conclude that Hodgkin's disease is a distinct pathologic entity, which may produce or be accompanied by high-grade anemia, usually of the secondary type, occasionally of pernicious type. The presence of histo-eosinophilia is not of great diagnostic significance, and surgical removal and competent examination of the involved lymph nodes may lead to an accurate diagnosis. Although tuberculosis of the lymph nodes and Hodgkin's disease may occur coincidently, tuberculous lymphadenitis may present a histologic picture somewhat confusing with that of Hodgkin's disease. The giant cells of this form of tuberculosis differ from those of Hodgkin's disease, in that the former show relatively solid nuclei, and the latter distinctly vesicular nuclei. Pending the discovery of the essential nature of the disease, it may be said

that Hodgkin's disease, a chronic granulomatous inflammatory process, may undergo transformation with assumption of malignant characters.

48. **Auscultatory Blood-Pressure Determinations.**—In 61 cases examined by Gittings the auscultatory maximum averaged 16.7 mm. higher than that determined by palpation. In 2 cases the reverse occurred, the palpatory maximum being higher than the auscultatory. In 1 case the difference was only 2 mm. and in the other 27 mm. In 41 cases diastole, as determined by auscultation, averaged 15.5 mm. lower than that determined by the visual method. In 5 cases diastole by auscultation averaged 7.7 mm. higher than that by the visual method. In 2 cases the results were equal. In 1 case diastole could not be determined by auscultation. In 11 cases diastole could not be determined by inspection. The maximum pressure being higher by the auscultatory method and the minimum being lower, it follows that the blood-pressure is greater in the auscultatory than in the visual method.

50. **Experimental Conditions of Low Blood-Pressure.**—The study of experimental conditions of low blood-pressure by Pearce and Eisenbrey has been limited, for the most part, to conditions of shock due to traumatism, thermic influences or exposure, and aside from the pharmacologic investigations of the mode of action of certain substances, such as arsenic, but few attempts to study experimentally low blood-pressure due to toxic agents have been made. The authors found that anaphylactic shock and peptone intoxication are characterized by conditions of low blood-pressure very similar to those seen in shock and collapse, and as they are produced without trauma or other factors usually concerned in the etiology of surgical shock, are of interest in the study of conditions of shock occurring in medical as contrasted with surgical practice. Both conditions are characterized by a fall in blood-pressure to a level of 20 to 30 mm. Hg, which is prolonged in anaphylactic shock, but tends to relatively rapid recovery in peptone intoxication. In both conditions there is extreme congestion of the large venous trunks of the splanchnic area with a coincident medullary anemia. The respiration is not altered, except in so far as it is affected by the anemia of the medullary centers; the heart shows no initial changes, the low pulse pressure being due apparently to the small amount of blood passing through it. Physiologic studies having for their object the determination of the mechanism by which the low pressure is caused, demonstrate that the condition is essentially a peripheral vasomotor paralysis. Pharmacologic studies indicate that the effect is on the nerve-endings rather than on the muscle. With independent cerebral transfusion the recovery from low pressure is more rapid than in the intact animal. This is true, also, when an animal is transfused by carotid anastomosis, and recovery is especially satisfactory when the transfusion is accompanied by simultaneous bleeding from the femoral vein.

Indications for treatment, therefore, appear to be (1) relief of splanchnic congestion, and (2) increase of volume of blood to the heart and medulla. Cardiac stimulants alone, or salt solution or adrenalin alone, cannot bring about a permanent improvement. According to the results, the treatment of this condition, which, for want of a better name, may be called toxic shock, is not essentially different from that employed in traumatic shock.

62. **Trichinosis.**—According to Thompson, there should be no difficulty in determining promptly a correct diagnosis of trichinosis based on the observation of the following symptoms:

1. Acute or vomiting and abdominal cramps.
2. A high invariably present; usually above 30 per cent. much higher—even above 80 per cent.
3. A high grade of temperature often reaching 104 F. or more, and lasting, in lessening degree, for from 2 to 6 weeks.
4. Puffiness of the eyelids and face, with pains in the eyes occurring in one-fourth of the cases.
5. Dyspnea and diaphragmatic breathing occurring without cyanosis in about one-fourth of the cases.
6. The generalized muscle pains, cramps, soreness, and prostration, causing sometimes deceptive apparent immobility.
7. The sudden occurrence of symmetrical circumscribed corneal hemorrhages in a patient whose blood vessels are not degenerated, should also give rise to a suspicion of trichinosis.

63. **An Epidemic of Trichinosis.**—The infection in the cases reported by Albert occurred from eating boiled ham in a club and in a restaurant. The ham in all cases was obtained from the same packing house, and represented meat which had been inspected. Ten of the cases occurred among students at one boarding club, 3 were young women students who, in company with 3 others, partook of ham sandwiches at a local restaurant, and 1 was a young man (not a student) who obtained ham at the same place. Most of the cases were diagnosed as trichinosis very soon after the beginning of the symptoms. The occurrence of so many cases among the members of the boarding house, the eating of boiled ham, the finding of trichinae in the ham, together with the characteristic symptoms, made the diagnosis comparatively easy. Some of the cases were considered typhoid, one as rheumatism, and one as disease of the eyes, until the diagnosis became very evident, as determined by an examination of the blood. In no case was a positive Widal reaction obtained. A study of the epidemic reveals two features of special significance—the thermal death point in trichinae, and the value of eosinophilia in the diagnosis of trichinosis. A temperature of from 170 to 200 F., maintained for from 1 to 6 or more hours, depending on the size of the ham, no doubt destroys the trichinae in the vast majority of cases. Eosinophilia occurs in practically every case of trichinae infection, varying ordinarily from 10 to 60 per cent. The highest percentage reported is 86. Eosinophilia makes its appearance with the beginning of the acute muscular symptoms from the seventh to the twelfth day after infection. It is at its highest at the height of the acute muscular symptoms, which is, ordinarily, during the second or third week after infection. After this time it gradually disappears, so that at the end of the second or third month there is usually no increase in the number of these cells. The total leukocyte count is usually, but not invariably, increased in trichinae infection. The number of neutrophils is relatively, and sometimes absolutely, diminished during the period of eosinophilia.

65. **Skin Rashes in Typhoid.**—Phillips' observations are based on a review of the literature, and on a study of 1,230 cases of typhoid. Herpes was observed in 12 cases. In 8 it

appeared on the lips during the first week of the disease. In the other 4 cases the hepetic eruption appeared late in the course of typhoid and in various regions of the body. Urticaria was present in 21 cases. In some the urticarial eruption developed as a few scattered wheals on the chest or abdomen, preceding the appearance of rose spots; in other cases it appeared later in the disease. A miliary eruption of sudamina was a very frequent occurrence in the third or fourth week of typhoid, when sweating is profuse. Extensive desquamation of the skin was noted in 83 patients; 7 showed erythema; in 1 it was of the type of erythema multiforme; in 6 purpura was noted; in 4 patients a pemphigoid eruption was present. Two cases of erysipelas occurred in this series; there were 12 cases of bedsores. Under the heading of septic conditions of the skin there were noted in this series 45 cases of furunculosis, 2 of carbuncle, 5 of onychia, 9 of abscess, 1 case of impetigo, and 1 of infected sebaceous cyst of the head. Striae patellares were noted in 2 cases, one in a woman, aged 42 years, who, when 15 years old, had been afflicted with a severe, prolonged typhoid.

67. **Rheumatic Fever and Erythema.**—The cases recorded by Schloss, examples of the erythema group of skin diseases, occurred in rheumatic subjects or in association with rheumatic fever:

1. Rheumatic fever, purpura; urticaria, angioneurotic edema; erythema simplex; recovery.
2. Rheumatic fever; erythema nodosum; purpura, urticaria; erythema exudativum; intestinal hemorrhage; pericarditis; death on the twenty-first day of the disease.
3. Follicular tonsillitis; erythema multiforme; urticaria; colic; recovery.
4. Tonsillitis; urticaria; erythema nodosum; period of improvement with the occurrence of angioneurotic edema; sudden onset of pericarditis; death.

69. **Typhoid Bacillus-Carriers.**—Simonds believes that there is ample evidence for considering the danger of the spread of typhoid fever by chronic bacillus-carriers as worthy of the attention of health officers; and that epidemics caused by bacillus-carriers are characterized by the occurrence of small groups of cases at intervals of a few months in the immediate vicinity of the carrier, or in the territory supplied by some food product handled by him. The most practical way of reducing the danger to the public from these individuals is by excluding them from work that brings them in contact with food products.

70. **Chronic Nephritides.**—The records of the last 200 cases of chronic nephritis that have come under Stern's observation, give the history of one or more acute infectious diseases at some period during the life of the patients in 192 instances. Among these an acute renal involvement had been positively set up in at least 121 cases. Moreover, the histories following the attack of the infectious disease in 56 or 58 of the remaining cases strongly point to the occurrence of an acute nephritic process. (Among these should be included 4 cases of tuberculosis, 5 of syphilis and 1 of chronic malaria.) Ignoring, however, all the unconfirmed instances, it was found that renal involvement had existed in 62.5 per cent. of the patients who had been acutely infected. The frequency of renal involvement after the various infectious diseases was as follows: Scarlet fever, 38 cases; diphtheria, 35; influenza, 16; pneumonia, 12; measles, 12; typhoid, 6; rheumatic fever, 1; and erysipelas, 1. Of the 200 quoted instances of chronic nephritis, 156 occurred in men and 44 in women. The age of the youngest individual was 8, of the eldest, 64 years. The 121 cases of chronic nephritis furnishing a positive history of acute renal involvement during or after an infectious disease, had ensued in 97 men and 24 women. The ages varied between 8 and 49 years. The time which had elapsed since the occurrence of the acute nephritic state amounted to from 10 months to 26 years. Stern believes we are justified in assuming that kidneys, acutely infected at one time, are thereafter possessed of a lowered degree of resistance in many, and of a diminished functional activity in some of the instances.

81. **Stretching the Sciatic Nerve.**—Instead of the usual longitudinal incision, Foote recommends a transverse incision made at the lower edge of the gluteus muscle, and only two inches in length. Division of the deep fascia—which is here very thin—exposes the transverse lower edge of the gluteus, and the longitudinal outer edge of the biceps muscle. In the angle made by them, the sciatic is readily exposed by a little blunt dissection and brought into view on the finger. The nerve should be stretched by repeated steady pulls on it, until it is plainly elongated. The force exerted should never exceed 50 pounds. An easy way to estimate this is for the surgeon to stand on a small platform scales, while making the traction on the nerve.

98. **Vincent's Angina.**—The cases of Vincent's angina reported by Holm were gathered during 1908 and occurred among 265 cases of suspected diphtheria, examined at the laboratory of the Michigan State Board of Health. In all the cases separate examinations were made from swabs and cultures on fresh Loeffler serum. In most of the cases which had been diagnosed as diphtheria on clinical grounds, 2 or more swabs were examined. In no case, however, examined for diagnosis, has a negative finding been followed by a positive. *B. diphtheriae* was recorded whenever present, regardless of the relative number; other organisms were not recorded, except when proportionately numerous, and then only the predominating organism was mentioned. *B. fusiformis* was recorded only when found by direct smear from the swab to be more numerous than any other.

The total number of cases examined for diagnosis was 265; showing *B. diphtheriae*, 118; *B. fusiformis*, 73. These 73

cases occurred in 33 males and 40 females. The lowest age given was 2 years and the highest 45, the average being 118 years. A membrane was described in all but 4 cases, involving both tonsils 38, one tonsil 31, and extending to adjacent structures 15. The color of the membrane was given as gray or grayish 41, yellow 9, white 8, grayish yellow 5, greenish yellow 1 and creamy 2. The highest temperature given was 103.6 F., the lowest 98.5 F., the average being about 100.5 F. The clinical diagnosis was given as diphtheria 28, suspicious or questionable 20, tonsillitis 17, Vincent's angina 5, and scarlet fever 1. The cultural results showed streptococci 29, staphylococci 20, *B. diphtheriae* 14, *M. catarrhalis* 8, pneumococci 1, Hofmann's bacilli 1.

In the entire series of 265 cases, diphtheria was diagnosed on clinical grounds in 99. The bacteriologic examination of these 99 cases showed *B. diphtheriae* present in 64 cases, absent in 35 cases. Among the 73 cases showing *B. fusiformis*, diphtheria was diagnosed clinically 28 times. The bacteriologic examination of these 28 cases showed *B. diphtheriae* present in 1, absent in 27. This gives a percentage in the clinical diagnosis of diphtheria in the presence of *B. fusiformis* of 96.4. The cultural results in this series of cases indicate that streptococci and staphylococci are the most usual in cases of Vincent's angina. It should be further noted that in over three-fourths of the cases of pseudodiphtheria, the direct smears from the membrane showed a predominance of *B. fusiformis*.

119. Autoplastic Transplantation of Bone.—For the cure of a recurrent tumor, Janeway resected a portion of the ulna five and one-half inches long, which ran through the center of the growth. A fragment of bone of the same length and three-eighths of an inch wide and one-eighth of an inch thick was chiselled off from the crest of the tibia, together with its adherent periosteum. This was then placed between the two extremities of the ulna remaining and fastened in place with silver wire. The periosteum of the implanted fragment was also sutured to the periosteum of the remaining portions of the ulna. The wound was closed, with the exception of a small drain at each end. In two months' time the patient could freely use the arm for washing clothes at a tub.

136. Chronic Appendicitis.—Stress is laid by Myer on the following points in arriving at a diagnosis of chronic appendicitis with gastric phenomena: A careful history should be taken with special reference to the previous existence of acute abdominal attacks, perhaps so far back as childhood. Primary gastric diseases should be excluded through a determination of the motility of the stomach, careful and, if necessary, repeated examination of the stomach contents, bearing in mind that there may be coexisting lesions in the stomach and appendix, and that in a small percentage of cases the acidity may be greatly increased—simulating ulcer, may be diminished—arousing fears of carcinoma, but, as a rule, is found within normal limits. In a differential diagnosis careful examination of the feces for blood, and of the urine, and examinations of the blood itself, will often throw light on obscure cases. Pure gastric neuroses, the expression of a neuropathic tendency, though less common than usually supposed, must be excluded, not forgetting, however, that organic lesions may be encountered in neurotic individuals. Especial care must be taken in cases of habitus enteroptoticus (Stiller) not to misinterpret the physical signs often elicited in these cases in both the epigastric and right iliac regions. Through the careful physical examination, other organs, especially the abdominal, must be excluded as a causative factor, not forgetting again that two lesions, such as gallstones and appendicitis, are not uncommon in the same individual. Lastly, there must be a most careful examination of the right iliac region for positive findings, bearing in mind that in exceptional cases of chronic appendicitis no local signs can be elicited. In the examination of the appendix region one or more of the following signs may be present: (a) Local pain on pressure over McBurney's point; (b) pain radiating toward the epigastrium on pressure over the cecum without, perhaps, any pain at the point of pressure; (c) epigastric distress and nausea on pressure in the appendix region; (d) Meltzer's sign, which consists in pain produced through the elevation of the right leg of the patient while exerting pressure over McBurney's point; (e) pressure in the left iliac region or other portions of the lower abdomen may cause pain to radiate to the right iliac region; (f) spasticity of the cecum; (g) borborygmus in the cecal region on manipulation; (h) exceptionally, in very slender individuals, the palpation of the thickened appendix; (i) pain and infiltration on right side occasionally elicited through rectal examination.

137. Typhoid.—The plan which has yielded the best results in Wilcox's hands has been the administration of the compound solution of chlorin, U. S. P., in doses of 1 dram every 3 or 4 hours, diluted in at least 2 ounces of water. This can

be given, he states, until all fetor of discharges is lost and until the temperature becomes normal. Wilcox says that with the use of this method (1) chlorin can safely be administered without fear of digestive or other disturbance until bacterial activity in the alimentary tract is markedly inhibited; (2) that under its use the tongue becomes cleaner and appetite and digestion improve, the fever is lower and the stools are devoid of odor save that due to the chlorin; (3) the general health, intellectual processes and nervous conditions improve; (4) the duration of the disease is shortened and the patient usually proceeds to a rapid, full recovery.

150. The Treatment of Wounds.—Preparatory work of all wounds, Jacoby says, should be similar, and any processes which may suit the personal preference of the surgeon will be equally satisfactory. After suturing the incised wound, he feels that an application of iodine is of value, and that a dressing of balsam of Peru in castor oil will aid in the removal of the gauze and give freedom from pain when the first dressing is applied. The lacerated wound should be swabbed with iodine and then followed by an application of balsam of Peru in castor oil, the dressing to be changed not oftener than every 4 days. The granulating wound requires nothing but a dry piece of gauze, which should not be removed, but left to act as a scab or graft. The surface covered with the gauze should be wiped off with peroxid of hydrogen and dry gauze reapplied. The dressing may be applied under such circumstances as frequently as one wishes, but Jacoby advises that it be done not oftener than once in 4 days, as it inflicts unnecessary traumatism and removes tissue growth. The clean operative wound should be examined in 48 hours and again 2 days later. An infected operative wound should be opened freely, and all gangrenous tissue excised, swabbed with iodine, and packed with balsam of Peru in castor oil dressing. The wound should be dressed daily

until the infection is controlled and thereafter every 4 or 5 days. The balsam of Peru in castor oil is 1 to 4 and the iodine used is the strong tincture. In abscess cavities Jacoby uses iodine irrigations, 1 dram to 2 quarts of hot water. The abscess cavity may be packed with the balsam of Peru in castor oil and left alone for 4 or 5 days. For the past year Jacoby has been trying an application of 50 per cent. in alcohol in infected cases with excellent results, but the alcohol solution must be applied daily or the dressing encased in rubber tissue. He believes that it is the ideal dressing in such cases and also in operations on the toes, where infection is liable to occur. It will also serve as an excellent pack in abscess and bone felon cases.

153. Dermoid Ovarian Cysts of Unusual Size.—The cases of dermoid ovarian cysts reported by Liell are of interest, not alone because of their enormous size—weighing, respectively, 42, 39 and 32 pounds; but in connection with the singular fact that all 3 were of the left ovary.

160. Varicocele.—The technic used by Johns is as follows: After resecting the veins by the "Bennett-Howse" method, a clamp is applied to the scrotum in such a manner as to allow the removal of the redundant portion. Twelve or fourteen silkworm-gut sutures are then introduced through the holes in the clamp, using long, slender, trocar-pointed needles. The ends of these sutures are then gathered into two bundles and clamped with hemostats. An incision is then made through the skin, with a sharp scalpel, about one-eighth of an inch from the clamp, the remaining tissues being cut through with strong scissors curved on the flat. The subcutaneous tissues, consisting of dartos and cremasteric fascia, are then sutured with a No. 0 plain catgut continuous suture, using a small round-pointed fishhook or fistula needle. The first turns of a surgeon's knot are then made in the silkworm gut, and drawn tight. The clamp is then removed, and after waiting a few minutes for the hemorrhage, which always follows removal of the clamp, to cease, the skin edges are brought together with a No. 0 plain catgut continuous suture on a long, straight needle. The silkworm-gut sutures are then adjusted and the knots completed. The reason for waiting to complete the knots is that they may be loosened and any bleeding points, which promise to give trouble, caught and tied. This is rarely necessary, but is very easily done, if need be, as the buried hemostatic suture prevents wide gaping of the wound even if all the silkworm-gut sutures are untied.

162. Traumatic Myositis Ossificans.—Following a severe blow on the thigh by a heavy piece of timber, Cohn's patient noticed a hard mass in the "fleshy part" of the thigh. Palpation disclosed a hard mass occupying the anterior and outer aspect of the lower two-thirds of the thigh. A feeling of crepitation was elicited on superficial palpation. The mass was not adherent to the skin. At the operation the mass could easily be felt in the belly of the quadriceps extensor, and covered the anterior aspect of the femur for about 6 inches; the lower limit could be felt about 2 inches above the patella, the outer border extending well beyond the limit of the femur. The mass was closely adherent to the periosteum. Recovery was complete and uneventful.

 179 *Banana Flour and Plantain Meal for Children Suffering from Diarrhea. A. E. Vipond, Montreal.

171. The Condition of the Lymphatic Glands.—In November, 1909, Forbes observed that the deep lymphatic glands in the iliac and inguinal regions were more likely to be enlarged in disease of the spine than in hip disease. He says that in early cases of hip disease it is most unusual to see a bilateral or even an unilateral enlargement of the lymph glands, whereas in lumbar Pott's disease and in tuberculous lesions adjacent to the lumbar region, such a unilateral enlargement is common, and a bilateral enlargement not uncommon in his experience. Five cases are reported illustrating the difficulties of the diagnosis between tuberculosis of the lower vertebrae and hip disease, and suggesting the possibility of the condition of the lymphatic system being a factor in the diagnosis. In all these cases the diagnosis of hip disease had been made.

172. Differential Pressure in Empyema.—Von Eberts believes that the widest field for the application of differential pressure is found in the treatment of empyema, where by its means and by the application of a suitable dressing after thoracotomy, the period of the disability may be very greatly curtailed. At the time of operation and at subsequent dressings positive differential pressure is especially suitable, as with a portable apparatus not only hospital patients, but also patients operated on in private homes, may enjoy the benefit of this method of treatment. Following thoracotomy an empyemic cavity remains exposed to atmospheric pressure. In extensive cases the whole lung may be collapsed and may lie in close apposition with the mediastinum. Further, the mediastinum and pericardium are not infrequently displaced toward the sound lung. Under such conditions, each inspiratory act results in the deflection of the mediastinal septum and collapsed lung toward the sound side in response to the negative tension produced on that side during inspiration.

With the use of differential pressure and the application of air-tight dressing, such as the one which von Eberts has devised, not only is the mediastinal deflection reduced, and the cavity thereby diminished in size, but the air within the abscess cavity becomes negative in tension during inspiration, and, in consequence, the mediastinum and pericardium tend to be further deflected toward the cavity and the collapsed lung to expand in the same direction. An immediate result of such a method of treatment is the prompt relief of the cyanosis. Apart from the curtailment of the period of disability, the absence of odor and of pain and discomfort of prolonged dressings, the earlier restoration of the collapsed lung to its normal respiration activity may remove to a large extent the danger of a subsequent tuberculous infection.

179. Banana Flour and Plantain Meal as a Food.—Vipond describes the good results he has obtained from the use of banana flour and plantain meal in cases of diarrhea in infants. He says it is a nourishing and valuable food and one that is easily digested, but not an ideal infant food, as the starch percentage is high and the fat percentage is low; however, it will tide over a critical period. The dextrose and starch in banana flour vary according to the method used in preparing the flour. It has remarkable astringent qualities, he states, as has also the plantain meal, a nice white flour, more palatable, but more difficult to obtain, and more expensive.

184. The Dull-Flat Percussion Note.—The percussion note described by Abrahams has been and is variously described as "diminished resonance," "relative dullness," "impaired resonance," "wood-like sound," etc., all graphic, says Abrahams, but none to the point. Technically, the dull-flat note is shorter in duration and higher in pitch; its acoustic qualities stand between dullness and flatness, or it is a note which is duller than dull. Abrahams emphasizes the fact that some areas of the lung normally possess dullness on percussion. Those areas are (1) the right apex and a finger's breadth under the right clavicle; (2) the intracapsular space, say from the seventh cervical to the fourth or fifth dorsal vertebra, and (3) in some instances the lower third of the base of the right lung. In the presence of an early infiltration, either of these areas drops its normal dullness and assumes the dull-flat resonance. This change in tone is unmistakable on light percussion. The dull-flat note is also of value in ascertaining the progress of the tuberculous process in any part of the lung. Take, for example, the left apex. Under normal conditions the percussion note of the left apex is pulmonary or vesicular. In the presence of an infiltration the vesicular resonance will change into dullness. Dullness indicates incipency. By watching the modifying degrees of the dullness in that apex and the eventual change of that note into the dull-flat, one can predict with accuracy the progress that the tuberculous deposit is making. It is evident that whereas lung areas which yield vesicular resonance on percussion may be said to be considerably advanced in tuberculosis when they yield the dull-flat note, areas which are normally characterized by dullness on percussion may be said to be in the incipient stage when they are possessed of the dull-flat sound.

188. Diplomellituria.—By diplomellituria Stern understands the contemporaneous or alternate occurrence of diabetic and non-diabetic glycosuria in the same individual. It is the result of two concurrent or intercurrent affections of dissimilar character having the one symptom, glycosuria, in common. The recognition of diplomellituria depends on the alternate prominence of one set of symptoms, including the respective glycosuria.

- 13 Serodiagnosis of Hydatid Disease: Fixation of the Complement. K. Eckenstein.

7. The Status Lymphaticus.—So far as our knowledge goes at present, Buxton believes we are compelled to admit that the case against anesthetics as the cause of death in status lymphaticus, is not proved. Their danger is probably the same as that incurred by any feeble child or adolescent and not more. The diagnosis of a case of lymphatism would not be a contra-indication to operation or the use of an anesthetic; it should, however, compel us to take special care in the direction of building up the physique of the patient before operation, when this is possible. These cases are not to be undertaken in a light-hearted way, they need the utmost care, experience and special attention, and no one, says Buxton, who values his peace of mind, should embark on the anesthetization in a case of lymphatism without adequate knowledge and skill and more than common experience.

12. Heart Puncture.—A girl aged 20 was healthy till the age of 18—two years ago—when she had rheumatic fever and lay ill for 3 months. The heart was damaged and she ever after had a mitral bruit, systolic in time, but with no dilatation and no anasarca. Six months ago she had a recurrence which left the heart still more damaged, and the apex beat was now always in the nipple line and one inch below. She had no evidences of failure till she was taken ill again with a cold and rheumatic pains. In addition to her cardiac condition there was well-marked hypostatic engorgement of both lung bases, chiefly on the right side. On May 23, there was dilatation of the heart one inch beyond the nipple to the left, and one inch beyond the right border of the sternum to the right. Milne perceived that heart failure was imminent, and that nothing but a reduction in the volume of the blood could avert death. He therefore proceeded to open the left median basilic vein but no blood flowed. He then opened the right median basilic with a like result. He cut deeper on the left into the brachial artery above its division into the ulnar and radial arteries, and only a feeble trickle of dark blood flowed. During all these manipulations the patient felt no pain, but lay half unconscious, with dilated pupils, cold sweats, cyanosed color and stertorous respiration, while the heart was getting more and more distended and Milne could feel no pulse in the temporals.

Milne then selected the fifth intercostal space, close to the left border of the sternum, as being in the circumstances likely to lie over the right auricle, since the distention had been more and more to the left. Having frozen the spot with ethylechlorid, he inserted a trocar and cannula of about the size of a No. 3 catheter vertically into the heart. Blood immediately flowed of about the color of porter and thick in consistency, and the cannula oscillated with the heart beats through an angle of about 25 degrees, inclining from the original vertical position to this extent to the right. The blood came in jets only when the cannula was vertical—that is, when its point was pulled to the right. Milne drew off 20 ounces and then withdrew the cannula and closed the puncture by acupressure. Almost suddenly the patient revived becoming quite clear and collected; she expressed herself as having felt no pain and as being quite relieved. A small probang was passed down the trachea and took up a lot of mucus. The patient was left in a different state altogether, with no cyanosis to speak of, and the venesections showing blood through their dressings. The pulse at the temporals was fair, the lips were pink, and the pupils normal, and when the sweat was wiped off no more appeared. This was at 3.30 p.m., the puncture having been made at 3.20 p.m. She remained clear and free from pain and distress till 7.20 p.m., when she died. Puncture of the heart thus prolonged life, in Milne's opinion, for four hours after the circulation was so feeble as not only not to make the opened veins bleed, but even the brachial artery was unable to show pressure at all.

- 17 An Unrecognized Form of Malaria. G. LeMoine.
- 18 Radium Treatment of Cancer. L. Wickham.

17. Unrecognized Forms of Malaria.—One of the forms of malaria described by LeMoine is malaria nostras, which he has encountered in the north of France. It is characterized by continuous fever without any marked rise of temperature. It may last for weeks, resembling tuberculosis or mucous fever far more than intermittent fever. LeMoine insists strongly on the presence of signs of consolidation of the right apex in malaria, especially in the latent form. The state of congestion is frequently met and naturally leads one to suspect tuberculosis, it persists for long periods in sufferers from malaria who have returned from the colonies, and is also seen in a milder and less persistent form in malaria nostras.

Medical men practicing in the district of Armentieres long since called attention to a form of malaria in which the symptoms affect a dyspeptic form. The victims gradually lose their appetite and complain of a feeling of oppression after meals, belching and evening vomiting. There are true symptoms of dyspepsia, but no treatment is of benefit unless associated with the administration of quinin. In these cases the liver can usually be felt below the ribs, and the spleen can be outlined on percussion. The patients may never have had an acute attack, yet for many years they have been impregnated with the malarial poison. Country practitioners often see patients who have almost constant fever with a tendency to persist for several weeks.

- 20 Migraine. G. Rankin.
- 21 Practical Points in the Management of Difficult Labor. H. R. Andrews.

20. Migraine.—The following prescriptions have often proved useful in Rankin's practice: (a) chlorid of ammonium, 15 gr.; phenacetin, 10 gr.; codein, 1-3 gr. (to be dispensed either in the form of a powder or of two cachets); (b) antipyrin, 10 gr.; salicylate of soda, 10 gr.; tincture of gelsemium, mxv.; spirits of chloroform, mxx.; water to one ounce; (c) heroin, 1-12 gr.; dilute hydrobromic acid mxxx; citrate of caffein, 5 gr.; compound tincture of cardamom, mxx; chloroform water to one ounce. In the case of all of them directions should be given for a dose to be taken every two hours for three doses; and every four hours thereafter until the pain is relieved. In women when the migrainous attacks recur only at the menstrual times, the use, for a week before each period, of a mixture of chloral hydrate, 10 gr., and bromid of sodium, 20 gr., given 3 times a day, is often successful, he states, in suppressing the attack or in diminishing its severity. When the temporal artery on the affected temple is prominent and throbbing, steady pressure over it may succeed in affording temporary relief.

26. Vincent's Angina.—Vincent's angina according to Rolleston is an uncommon disease, occurring in 0.9 per cent. of all cases of sore throat, and in 4.9 per cent. of cases of non-diphtheritic angina. During a five years' period of observation in a hospital population of all ages, the affection was confined to children between 2 and 16 years. No instances of contagion were observed. Its incidence was greatest in spring, least in autumn. It was not found to show any predilection for weakly children or for cases of oral sepsis. There is nothing characteristic in its prodromal symptoms. Rolleston holds that there are not two distinct varieties of Vincent's angina. The ulcerative is merely a later stage of the membranous form. Constitutional symptoms are slight or

71. Hemostasis by the Momburg Belt Constriction.—Burk reports three cases in which the Momburg belt constriction was applied but the experiences were not encouraging. Momburg's technic was strictly followed and in two cases no special influence on the respiration was observed or notable fluctuation in the blood pressure. In the third case the patient was a seamstress of 29, operated on for removal of a vulvar fibroma. The pulse and respiration were good during the operation and after removal of the tubing, but an hour later the pulse became imperceptible. It revived under saline infusion with a few drops of a solution of the active principle of the suprarenal gland and was at 160, persisting small and thready and varying from 140 to 160 for 24 hours. The operation had been done under veronal-scopolamin-morphin-ether general anesthesia. The heart remained very weak and severe enteritis developed but there was no rigidity of the abdominal wall, probably from injury of the innervation from the Momburg belt technic. The patient succumbed the next day with signs of diffuse peritonitis, and autopsy revealed patches of gangrene in the small intestine with resulting peritonitis. The circular strips of suffusion in the walls of the loops of the small intestine were unmistakable signs of direct strangulation from the constricting tubing. He explains the severe injury of the intestine in this case, while nothing of the kind was observed in the 34 other cases on record in which this Momburg technic has been applied, as owing to the fact that the patient was very thin and debilitated. This mishap warns against the use of this technic for very thin persons or when there is an ulcerated or chronic inflammatory condition of the intestine. Another possible danger is an ischemic paralysis of the distal end of the spinal cord, which Pagenstecher observed in one case.

72. Releasing Constricted Nerve after Fracture of the Radius.—Els reports most encouraging results from neurolysis to release the nerve from an unfavorable position or from secondary cicatricial callous growth. No harm seems to have resulted from the operation. His patients were three young men, a young woman and a boy of 8. He gives the details of each case.

75. Congenital Scoliosis.—Kayser has been able to find only between 50 and 60 cases of congenital scoliosis on record and he gives an illustrated description of another case. His patient was a girl of 9 of healthy parents and healthy herself except for the cervico-dorsal scoliosis. Until the spine was examined with the Roentgen rays the slight deformity had been attributed to cervical ribs.

80. Acute Perforation of Gastric and Duodenal Ulcer.—Finsterer reviews the experiences at the surgical clinic at Graz with 18 cases of perforation of gastric or duodenal ulcer in the last ten years, and emphasizes that the fate of the patients rests in the hands of the physician who sees the case first, as salvation lies exclusively in an early operation. Even if 12 or 24 hours have elapsed, operative treatment should be tried, he asserts, as a few cases are on record of recovery even after an operation as late as the seventy-second hour in extensive peritonitis. He advocates copious rinsing with warm salt solution, aspirating it out again with the Luksch aspirator, as the safest and best method of treatment after the operation.

81. Differential Pressure.—Tiegel gives an illustrated description of the simple apparatus with which he induces positive pressure in the lungs in the course of operations on the chest as he has applied it in 8 cases. He also reports experimental and clinical research which has shown that a small amount of oxygen given during the positive pressure is able to keep the subject in good condition even when the lung is collapsed. A very slight degree of positive pressure in the intrabronchial air does not injure the lung, he says, nor the conditions in regard to the circulation, while it aids

in preventing severe postoperative atony of the stomach. He warns that the tanks should be tested before using the gas; once he had a tank of carbonic acid gas sent by the dealers by mistake. He regards his demonstration of the fact that respiration of pure oxygen under a minimal pressure (1 cm. water) is sufficient to supply the need of oxygen, as an important progress. The arterialization of the blood is more extensive with it even than with ordinary respiration. The lung does not have to be inflated much when the pure oxygen is used, and thus injury from the pressure is avoided.

82. The Hand in Obstetrics.—Liepmann discusses the indications for the use of the hand as an instrument to aid delivery and the various manual maneuvers, lauding Hofmeier's in combination with the Walcher position as particularly serviceable with contracted pelvis. In placenta prævia he advocates Strassmann's method of making external version on the breech and then with two fingers drawing the foot down through the cervix, declaring that this is far simpler and less dangerous than the combined Braxton-Hicks version or the use of the inflatable bag. He knows of an instance in which the forceps introducing the bag perforated the vault of the vagina. At the same time he warns against using the hand to dilate the cervix in case of placenta prævia; trained judgment is required to select the cases in which this can be done. In conclusion he describes what he thinks is a new maneuver to guide the head exclusively with the hand through the pelvic passage to safe delivery. The anesthetized patient lying across the bed, the right hand is placed on the fundus of the uterus to aid in expression and the left hand, gloved, is introduced into the vagina, where it serves to dilate the vagina, then to dilate the os, then to rotate the head and finally to extract it. When the hand is deep in the vagina, the fingers are spread, thus dilating the vagina, and making it possible to grasp the head as one grasps a ball. By a combination of pressure from without, turbinal rotation and cautious extraction, the head is finally worked past the perineum. It is astonishing, he exclaims, how firmly and safely it is possible thus to grasp the head, taking it in the hand like a tennis ball. In a case described, the woman, a iv-para, had a temperature of 103 F., pulse 110, the internal os being dilated about the size of one's palm, the head impacted in the pelvic outlet. The consultants advised the inflatable bag, then an attempt at forceps and in case this failed, perforation. While the instruments were being made ready, Liepmann delivered the child in less than five minutes. Even if this maneuver does not succeed, it at least provides much better conditions for applying forceps, and is useful when there is reason to fear that the forceps will slip on account of the smallness of the head, in premature deliveries and at twin births. The largest child he has thus delivered weighed 3,000 gm., and was 50 cm. in length. The article is illustrated.

95. Pathologic Electrocardiograms.—Pribram and Kahn analyze the findings in 300 electrocardiograms taken of various patients with different forms of heart disease. Seven large tables give 129 electrocardiograms for study of the details.

96. Nature and Treatment of Hemophilia.—Sahli has continued his research on 4 typical hemophiliacs and also on 2 new ones, striving to obtain better insight into the nature of hemophilia and to explain the phenomena observed by various authors. His assumption is that hemophilia is an anomaly of the cellular elements of the blood and of certain other cells, especially in the walls of the vessels, entailing defective production of thrombokinase. This latter factor is evident when the bleeding continues although the coagulating property of the blood after much loss of blood may be normal or above. The practical lessons from this work are that the hemophilia may be constitutionally influenced by repeated injection of fresh human blood serum for the purpose of thrombokinase enrichment by the intermediate link of antikinase production. Another way is by repeated withdrawal of small amounts of blood by puncture of a vein with a fine cannula, for the similar purpose of thrombokinase enrichment, by means of the physiologic reaction that follows. Experience has shown that there is no danger of hemorrhage in a hemophiliac if the vein is punctured with a fine cannula, permitting harmless withdrawal of blood and the consequent physiologic reaction. An ordinary venesection might prove dangerous. Two of his patients are brothers and another is their uncle and two other uncles died of hemorrhage.

97. Encephalitis after Whooping Cough.—In the case reported, a healthy boy of 6 was convalescing from a moderate attack of whooping cough when febrile general symptoms developed soon accompanied by right hemiplegia and loss of voice. The paralysis gradually subsided but months later there are traces of the cerebral hemiplegia. In 5 similar cases on record autopsy revealed a hemorrhagic encephalitis, such as is the rule with influenzal encephalitis.

99 and 100. Commented on editorially in THE JOURNAL, Aug. 13, 1910, page 601.

101. Operative Treatment of Apoplectic Stroke.—Franke advocates operative intervention in case of acute cerebral hemorrhage, before irreparable changes have been induced from compression by the extravasated blood. The brain seems to be able to stand without serious injury considerable compression if the strain is not kept up too long and if the blood is evacuated before the brain-tissue has softened under its direct influence and its toxic action. In a recent case, the autopsy findings when compared with the course of the syndrome impressed him with the conviction that operative treatment after the first shock would in all probability have saved the patient. Puncture of the brain or trephining would have released the blood, especially if a fine metal can-

nula with holes in the side had been slipped in over the needle and left in the opening for permanent drainage. He trephined in the case reported but not until two weeks had elapsed after the hemorrhage; irreparable harm had already been done and the patient soon succumbed. He makes the trephine opening with the Gigli wire saw and remarks that the dangers of puncture and trephining are negligible in comparison with those which cerebral hemorrhage entails. Minute examination and observation are necessary to locate the site of the hemorrhage; the most apparently insignificant signs must be watched for and noted, for example, slight paresis of the facial muscles, mouth breathing, behavior of the abdominal and cremaster reflexes, which are diminished or abolished on the paralyzed side, the Babinski reflex on the side involved, slight tension of the extremities during passive movements on the sound side, conjugated deviation of the eyes toward the side involved or a history of some preceding slight apoplectic attack and determination of the site of the hemorrhage at that time. He urges that a surgeon should be called in during the first few hours after a serious apoplectic stroke so that the physician and the surgeon can study the case together, locate the hemorrhage and discuss whether the condition permits of operative intervention or is not serious enough to demand it. The puncture could then be done at once in the home; if this fails to give relief, trephining might follow. He does not think that a cautious removal to a hospital would essentially increase the dangers for the patient. By this means the blood could be removed from the brain within 2, 3 or 5 hours, this period of time being allowed to elapse to permit revival from shock and reduce the danger of serious after-hemorrhage. The practitioner generally is the one who first sees patients with cerebral hemorrhage, and to him Franke appeals to help place cerebral hemorrhage on the same plane of successful treatment as perforation of a viscus, stab wounds of the heart and acute peritonitis.

116. Organotherapy in Surgical Prophylaxis.—Siegmund declares that the technic of the surgeons cannot be perfected much further and yet the outcome of operations is still a matter of chance in a great degree. This is owing to the individual conditions of tolerance and resistance in the different cases, just as one person contracts typhoid while others equally exposed escape. Two recent cases in his experience suggest that this individual tolerance and resistance may be due to the individual functioning of the ductless glands, the thyroid in particular. In one of the cases a woman of 34 had displayed from childhood a tendency to suppuration on the slightest excuse. Like a hemophiliac's hemorrhages,

she produced pus on the least provocation, and naturally there was extensive suppuration after an injury of the arm from broken glass. In the other case the reverse was observed; the woman of 43 suffered from distressing subjective symptoms of sclerosis of the middle ear and was also nearly blind. In order to relieve the tormenting roaring sounds he made a seton in the back of her neck, having cured another patient by this means of incessant vertigo and headache, chronic through years, and the cure has been complete for several years to date. But in the present case there was no suppuration in the seton although he tended it carefully every day. In both cases the outcome of the surgical intervention was not as the surgeon willed but as Nature willed. The only way in which the surgeon can obtain his purpose is by following the trail blazed by Nature, and Siegmund thinks this can be done by organotherapy. The way to do this was suggested by a third case in which a wound on the head of a small child suppurred interminably until he noticed that the other, older children in the family showed signs of thyroid insufficiency. Notwithstanding that the youngest was robust and lively, he reasoned that a family tendency to defective thyroid functioning might be the cause of the persisting suppuration, and this assumption was sustained by the rapid healing of the wound under thyroid treatment. His other 2 patients also presented signs of thyroid insufficiency and he believes that thyroid treatment is also indicated for them. Prophylactic thyroid treatment in puerperal sepsis has many arguments in its favor, he explains, and calls attention to the fact that the thyroid may have brief periods of disturbed functioning when at other times it does its work normally. Siegmund regards this as a virgin field rich in promise. Each ductless gland evidently produces a number of substances in its internal secretion, each of which has a different action, the lack of one or more entailing myxedema, exaggerated pus production, etc., as the case may be. The more of these substances we can isolate and use, the more scientific the organotherapy, but even with the thyroid preparations already at our disposal it is possible to solve many of the present questions in respect to constitutional predisposition, suppuration and granulation of wounds, production of protecting substances in the blood, phagocytosis, therapeutic hyperemia, etc.

July 14, XXVIII, No. 28, pp. 865-896

120 Hernias. F. Kayser.

121 *Regulatory Albuminuria. F. C. R. Eschle.

121. **Regulatory Albuminuria.**—Eschle applies this term to the albuminuria liable to be observed after excessive physical exercise, with suppuration elsewhere in the body and after chilling, a transient elimination of albumin for which the kidney is merely the outlet without being responsible for its production. This regulatory albuminuria is also liable to be observed, he says, with diarrhea, with anemia in the young and with amyloid degeneration, the loss of fluids leaving an excess of albumin in the blood which is then thrown off through the kidneys. The albuminuria in these cases is often attributed to kidney disease, but the normal amounts of urine and lack of uremic brain symptoms speak against this. It is a grave mistake, he declares, to treat an anemic young patient as for a tuberculous kidney disease when quite other measures are needed. The kidneys rarely seem to suffer from the task of eliminating the extra amounts of albumin with these regulatory processes unless the albuminuria is intense and long continued, as in diabetes.

122. **Neuropathology of the Eyes in Psychoses.**—In the first case described the visual field became restricted according to the hemianopsia type in the course of a hysterical disturbance with hallucinations, and yet the hemianopsia was merely functional. It could be influenced by suggestion but always returned to the former type. In the second case total rigidity of the pupils was observed in a young drunken man, the intoxication having been induced by a small amount of alcohol after emotional stress. This transient rigidity of the pupils was also observed during the alcohol intoxication of an imbecile young man.

123. **Surgical-Orthopedic Treatment of Infantile Spinal Paralysis.**—Wette remarks that the results of treatment are better the simpler the method of correction used and the greater the attention that is paid to the after-treatment. In some cases it is necessary to wear the correcting apparatus for years after the operation to ensure a permanent and complete cure. Fixation is always necessary for at least three months.

127. **Hyperemia in Internal Diseases.**—Weidenbaum has been applying constriction or suction hyperemia as a routine measure in treatment of gall-stone and liver troubles, sciatica, leg ulcer and asthma during the last five years, and has been much gratified with the good effects obtained. In more than 100 cases of gall-stone and catarrhal liver enlargement, the application of a large suction bell over the liver region gave almost immediate relief, the pains and the swelling of the liver rapidly subsiding. The effect is very striking in gall-stone colic, the whole attack being aborted by the action of the large cupping glass, so that now he always applies the suction bell or hot air box before giving morphin even in the severest attacks from gall-stones or kidney stones; it frequently renders the sedative unnecessary. In some cases the pain increases under the suction bell, and the temperature rises; when this occurs the trouble is invariably empyema of the gall-bladder, and this differentiates the condition at once. The superheated air box answers the same purpose as the cupping bell and is preferable for nervous patients or when the skin is sensitive. With kidney-stone colic and sciatica the suction bell gives the greatest relief, the bell being pressed firmly down over the kidney or the sciatic foramen. In a number of cases of diabetic polyneuritis in which the pains had resisted all other measures, they subsided under a constricting band. Great care is necessary to keep changing the position of the band, moving it up or down and constantly instructing the patient to warn of the slightest sensation of discomfort, as otherwise decubitus might develop under the band. Notwithstanding this grave danger, he asserts that the great service rendered by the band in some cases justifies its use. In a typical case of this kind a woman of 54 with arteriosclerosis, advanced diabetes and cardiac insufficiency, had suffered for six months from severe polyneuritis and diabetic xanthoma. The incessant pains and sleeplessness and the medicines she had been taking during this time, as she was constantly under the care of eminent authorities in metabolic disturbances, had reduced the patient to such an extent that she was unable to leave her bed. At once on application of the constricting band the pain subsided and she had a good night's sleep, the first in months. By the fifth week the polyneuritis had disappeared and with it the xanthoma. A recurrence a year later disappeared again in the same way under the same measures. The xanthoma had been most pronounced on the back in this case and its subsidence confirms Bier's claim that the hyperemic treatment stimulates blood production in remote parts. The hot air box may be preferable for diabetic gangrene; he has had good results from its use for this purpose, as also for old rebellious leg ulcers. An extensive leg ulcer on a patient with a mild form of diabetes had resisted all treatment for years, but healed in 5 weeks under superheated air treatment. When only a single limb is to be treated, he applies the hot air

box now for all cases of diabetic neuritis and neuralgia. The suction bells have also proved effectual in relieving respiratory disturbances. Several large cupping glasses applied between the shoulder blades gave relief at once in cases of bronchial asthma, emphysema of the lung and dyspnea from cardiac insufficiency; and essential improvement followed systematically continuing this treatment. In a case of uremia it proved possible by this means to check effectually the dyspnea and convulsions.

132. Peptic Ulcer in the Esophagus.—Kappis reports a personal case and compares it with fourteen on record in which the peptic ulcer was confirmed by autopsy. None of the cases had been correctly diagnosed which is not surprising as in only five cases were there any symptoms on the part of the esophagus, pains or difficulty in swallowing and in three of these gastric disturbances predominated. Regurgitated gastric juice or islands of gastric mucosa aberrant in the esophagus and secreting a peptic juice seem to have cooperated in some of the cases. Regurgitation of the gastric juice into the esophagus was favored by stenosis at the pylorus or duodenum or by hour-glass stomach in seven cases and in most of them the cardia was much enlarged. In eight of the fifteen cases there were coexistent gastric or duodenal ulcers. Dietetic measures should be instituted on suspicion of peptic ulcer in the esophagus or direct endoscopic local treatment. The most effectual measure, however, is prompt gastrectomy which rests the esophagus and gives it a chance to heal, thus warding off impending hemorrhage or perforation. An important point, however, is that peptic ulcer of the esophagus is generally secondary to some lesion elsewhere and removal of the primary cause is essential.

133. Operative Treatment of Exophthalmic Goiter.—Leischner and Marburg discuss this question on the basis of forty-five cases in which an operation was done in the university clinic at Vienna in charge of von Eiselsberg. Persistent large thymus was responsible for one of the five fatalities, the status thymicus being accompanied by severe degeneration of the heart. Pneumonia in a tuberculous and much debilitated woman of 46 proved fatal in another case and recurring apoplexy in another. The fifth fatality was in a case of advanced heart disease, compression from the enlarged thyroid compelling operative treatment as a last resort. Among the cured patients were some with persisting thymus which is thus seen to be not a contraindication for operative treatment, unless complicated with heart disease or cachexia. Removal of half of the goiter is the preferred technic; the arteries are not ligated unless the patient is much debilitated. The conclusions are that operative treatment is indicated with compression and for social motives but only relatively indicated with cachexia increasing refractory to treatment or subjective disturbances becoming unbearable.

134. Syphilitic Disease of the Spine and Base of the Skull.—In Petren's first case the syphilis induced caries of the second cervical vertebra and likewise a recurring meningeal affection mostly localized in the vicinity of the syphilitic bone process. In two other cases the localization of the bone process was about the same, as also in forty-two cases he found on record. It seems evident that the cervical vertebrae afford a predisposition for the localization of syphilis. In seventeen of the cases a complete cure was realized by appropriate measures against the syphilis. In the thirteen fatal cases there had been scarcely any attempt at specific treatment. It was noticed in some of the cases that the pains and tenderness were predominantly or exclusively on one side which may possibly help to differentiate this affection from rheumatic disturbances. The Roentgen rays first suggested the possibility of caries of the base of the skull, and then certain neurologic phenomena in some of the cases.

136. Latent Stenosis of the Pylorus.—A similar article by this author was summarized in THE JOURNAL, May 21, 1910, p. 1732.

137. Unilateral Suppurating Nephritis.—Baum applied nephrotomy in the 3 cases of acute hematogenous nephritis described. Recovery was not only prompt and complete but functional tests of the kidneys nearly a year later showed practically complete recuperation. The chief danger of conservative surgical treatment is that the bacteriuria is left and it may prove a source of infection. In one of his cases the other kidney became involved and presented a transient syndrome indicating brief mild infection. Hessert, however, has reported a case in which even nephrectomy did not protect the remaining kidney from secondary infection.

139. Surgery of Non-Malignant Stomach Disease.—Lieblein has operated in 15 cases in the last 5 years including 3 of perforation. His experience teaches that gastroenterostomy is still the best method of treatment in cases of open gastric ulcer when there is no suspicion of cancer. Careful and prolonged internal treatment is required after the operation, sometimes a long interval elapsing before the clinical cure. The ulcers at the pylorus, even those of a callous or penetrating character, indicate gastroenterostomy rather than resection, but the tendency to cancerous degeneration displayed by ulcers in the lesser curvature or rear wall of the stomach imposes more radical measures, transverse resection of the stomach or typical pylorotomy. Cancerous degeneration followed in 2 of his cases of this kind, and in future he will be more radical in operating. The callous and penetrating ulcers generally had caused symptoms for years, and the comparative harmlessness of operative treatment in this class of cases and the good results justify, he thinks, an earlier resort to surgery.

145. Prevention of Postoperative Thrombophlebitis.—Schweninger states that 22 cases of femoral thrombophlebitis were encountered in the total 1,315 patients operated on between 1905 and 1909 at the Munich polyclinic for women's diseases, and study of these cases emphasizes the importance of toning up the system before undertaking any serious operation. Even at the best, a major operation, he remarks, must be regarded as a serious trauma and a grave danger for which the organism must be prepared. Flabby tissues should be toned up if possible beforehand, and for this it is not enough to send the patient to the country to follow her own inclinations—in many cases the trouble in question is the conse-

quence of an irrational mode of life. The patient should be under medical care and diet, massage and hydrotherapy should be applied systematically under the physician's directions. The after-treatment should be graduated to the patient's general condition: passive stimulating treatment during recumbency, frequent change of position, massage, sponging off and cool sleeping; then more active measures, the patient still being kept recumbent, and finally active measures out of bed, walking, breathing exercises, etc., in progressive dosage. Under all circumstances it must be borne in mind, he adds, that standing still, erect, is the most injurious position for the circulation and should be avoided the longest.

148. Rupture of the Cicatrix after Cesarean Section.—Dahlmann reports 3 cases of this accident and has collected 23 from the literature. In 17 of the cases the pelvis was much contracted, and in 2 there was a tumor. In 10 cases the incision had been median, in 12 transverse. The chief factor inducing conditions favoring rupture later is the lack of primary healing of the Cesarean wound. In 20 of the 23 cases in which the outcome is mentioned, the mothers were saved but only 5 of the children in 22 cases.

150. Rachitis.—Czerny defines rachitis as a congenital constitutional anomaly whose most prominent symptom is the change in the bones and cartilages. There is evidently a general nutritional disturbance affecting the bones and inducing symptoms on the part of the nervous system. The latter may even be the primary trouble. Lack of sufficient lime in the food is evidently a factor in the syndrome, and this may occur even with breast feeding if the child did not bring an ample supply of lime with it into the world. Dietetic treatment in time has an essential influence on the course of rachitis.

152. Albumin-Milk in Infant Feeding.—The formula for Finkelstein's sugar-poor mixture was given in these columns, July 2, page 93. Birk reports its use in 30 cases, his experience confirming that of others in regard to its doing good service in acute and chronic alimentary disturbances. By thus reducing the proportion of sugar and restricting fermentations in the intestine, the infant's tolerance for fat is increased.

160. Germ Carriers and Epidemic Meningitis.—An unusually extensive and painstaking bacteriologic examination was made of the troops in garrison at Munich to determine the prevalence of healthy carriers of meningococci. There had been an epidemic of cerebrospinal meningitis in the garrison

the year before. It was found that nearly 2 per cent. of the 9,111 healthy men examined once harbored the germs and they were found in 2.46 per cent. of 1,911 examined a second time. From these findings in 11,022 healthy persons it seems evident that the germ is ubiquitous both during and outside of epidemics. Study of the epidemic there and of epidemics elsewhere seems to demonstrate that the epidemics die out spontaneously, regardless of what measures may be taken against them beyond the indispensable institutional isolation of the sick and general hygienic measures. It seems hopeless, the authors say, to attempt to control the disease on the same principles as typhoid and cholera are controlled, the conditions being so different.

- 175 Case of Simultaneous Tabetic Gastric Crises and Tetany. W. Buettner.

171. By-Effects with Ehrlich's "606."—Bohac and Sobotka report the occurrence of a set of symptoms in 3 out of 14 patients being treated with Ehrlich's new remedy for syphilis. These unexpected by-effects were retention of urine for from half a day to over 9 days, abolition of the knee-jerk and of other common reflexes and extreme rectal tenesmus with tenacious constipation. This syndrome occurred in a more or less pronounced form in these 3 patients with moderate doses, suggesting that the symptoms might have been alarming if the dose had been a little larger, as they indicated a paralysis or inhibition of certain nervous elements. The syndrome resembled that observed in some cases after administration of atoxyl, but impurities in the drug may have been responsible for it. The experiences related are from the dermatologic clinic at Prague in charge of Kreibich. In other respects the experiences confirmed the claims made for the new remedy by Ehrlich and others. And notwithstanding the untoward by-effects observed in 3 out of the 14 cases, the clinic does not intend to abandon the use of the remedy but will reserve it for the cases in which the ordinary measures are contraindicated for any reason or have failed completely. It will also be used in cases in which the pains or malignant character of the disease, threatening serious functional disturbances or disfigurement as from numerous localizations of malignant syphilis, compel urgent measures—the patient being always fully informed as to the dangers and "untriedness" of the new method of treatment.

174. Simple Method of Estimating and Recording Deformities.—The lack of a simple method for recording the extent and the changes in scoliosis and other deformities has long been felt by orthopedists. Semeleder has found a stripe technic a reliable means of tracing the progress of the patient under treatment and of impressing the patients and their friends with the necessity for treatment or its continuance. The patient stands against a wall and the shadows of a number of horizontal lines are thrown on his body as a photo-

graph is taken. On a plane surface the stripes are even and straight but on the body they assume fantastic curves, bringing into prominence any deviation from symmetry. He has the camera mounted on a frame on a level with the

Fig. 1.—W, wall; F, camera; P, light, with lines on slide; S, Standard on which the camera and lantern pivot.

Fig. 2.—Lines thrown on patient's back.

patient's head; the light throwing the shadow of the lines is mounted on the same frame near the floor, each pivoting so that the axial center lines from each meet at the center of the area to be photographed.

178. Hypertrophy of Bladder Trabeculae as Early Sign of Tabes.—Frohnstein examined the bladders of 20 patients at Moscow with unmistakable or suspected tabes and found that the walls of the organ showed signs of excessive muscular effort in every case of tabes. Sometimes this was the first sign of the disease, the course later confirming its specific character. As the bladder has to make more of an effort to void its contents on account of the encroaching spinal cord disease, the walls develop ridges like beams. These beams in tabes are delicate but regular and are found on both the side walls and fundus. The sensory paralysis of the bladder mucosa weakens the impulse to empty the bladder; urine accumulates and dilates the bladder and the walls hypertrophy from the compensating extra muscular effort required.

182. Circular for Parturients.—Reich reproduces the circular which is handed to each woman on leaving the maternity after childbirth. It gives from 6 to 8 paragraphs of directions "For the Mother" and "For the Baby," commencing with the statement that the "confinement" lasts from 4 to 6 weeks, not merely the few days the woman is in the hospital. It adds that during these weeks the woman is especially liable to take cold, to bleed, to contract diseases and to have the womb get out of place. At the least sign of a chill, passage of pure blood or abdominal pain she must apply for medical aid without delay. The most dangerous consequences are liable to follow resumption of conjugal intercourse before the end of the fourth to sixth week.

- 188 *Masked Tuberculosis. (Le tubercolosi larvate.) G. Jona.

188. Masked Tuberculosis.—Jona discusses the various forms of what he calls "masked" tuberculosis, the healed and latent forms, the complicating and the obscure and especially the form with jaundice which nothing but tuberculosis can explain. The form in which tuberculous infection of the glands simulates a febrile pseudoleukemia is not so rare as the scorbutic form; he has encountered a number of examples of each. In a case of the latter reported by Senator there was nothing during life to suggest the tuberculous nature of the scorbutus and autopsy alone showed that the tuberculosis was not only the predisposing but the essential factor in the scorbutus. Several similar cases have been

reported since. Jona has had 4 patients in his charge with tuberculosis inducing jaundice. This syndrome developed in a child of 8 with irregular fever, headache and great prostration for a month with increasing jaundice and diarrhea, but autopsy showed the liver and bile passages in comparatively normal condition and the latter unobstructed. In another case the jaundice developed during the last week of an acute miliary tuberculosis. In another case the jaundice persisted for two years and the liver was much enlarged. Autopsy disclosed tuberculous cheesy glands and amyloid liver but the lungs were nearly intact. There had been no suspicion of tuberculosis in this case, all the signs pointing to the liver. This tuberculous jaundice is the result of great destruction of red corpuscles by the toxins, the hemolysis being evident in the gorged phagocytes crowding the liver and spleen. Even a concomitant cirrhosis of the liver is not necessarily responsible for the jaundice.

- 195 *Chemical Examination of Urine in Diabetes. C. Geelmuyden.
- 196 *Review of 113 Cases of Mammary Cancer. (Bidrag til mamma-carcinomernes statistik.) N. Paus.
- 197 Importance of Experimental Pathology for Study of General Biologic Phenomena. M. Haaland.

194. Congenital Myxedema.—Døderlein's case is a striking example of the peculiar, far-reaching importance of the thyroid for the physical and mental growth and development, and the lack of both with lack of thyroid functioning. The child was born with typical pure myxedema and at the age of 4 looked still like a 10-months babe, being a pronounced idiot. No traces of the thyroid could be discovered on palpation. Thyroid treatment was then commenced and in 3 months the child was transformed under its influence, it had grown 10 cm. in height and has developed normally since, and is now lively and healthy.

195. Chemical Examination of the Urine in Diabetes.—Geelmuyden emphasizes the importance of estimating the degree of auto-intoxication in diabetes by examining the urine, and reiterates that the tests for acetone and oxybutyric acid are too complicated for general use. The proportion of ammonia, however, is readily determined, and is a reliable index of the acidosis and thus a faithful guide to treatment.

196. Mammary Cancer.—Paus analyzes the experiences of 16 years with cancer of the breast, a total of 113 cases; 37 non-malignant mammary tumors were also encountered during this period. In the 113 cancer cases, 68.8 per cent. of the women were married and from 14 to 21.9 per cent. had had over 6 children. In 2 cases the tumor was first observed during lactation and in another case during a pregnancy. The ultimate outcome is known in 70 cases and 20.3 per cent. of these patients have been free from recurrence for over 5 years since the removal of the cancer; 31.4 per cent. for over 3 years. The recurrence was local in 60.4 per cent. of the 53 recurring cases; 27 in the first, 1 in the second and 4 in the third year. Rheumatoid pains after the third year were the first signs of metastasis in one case, but with nothing to suggest their malignant origin for another year. Only one of the patients was a man. He was a laboring man of 31, who first noticed the lump in his chest at the age of 15. It gradually increased to the size of an egg but caused no symptoms until a contusion of the chest started it to rapid growth and it was found inoperable 3 months later. The prognosis of mammary scirrhus is better than that of carcinoma. Paus'

advice is to remove every tumor in the breast at once, whether malignant or not. "Rather no breast than a cancer breast," he quotes. He tabulates his material from various standpoints and compares it with that of others.

Ugeskrift for Læger, Copenhagen

July 21, LXXII, No. 29, pp. 859-884

- 198 *Cancer of the Throat. (Kliniske Bidrag til Strubekræftens Patologi.) E. Schmiegelow. Commenced in No. 28.

198. Cancer of the Throat.—Schmiegelow entreats the general practitioner to appreciate the fact that there are very few organs in the body from which cancer—diagnosed in time—can be removed with as good prospects of a complete cure as from the throat. He has encountered 48 cases of primary endolaryngeal cancer, the patients all male but 8, and all were over 40 except one woman in the twenties and one man and one woman in the thirties. The growth was in the vocal cords in the majority, and hoarseness was the first symptom to call attention to the throat in 37 cases. As a rule the hoarseness developed gradually but in a few cases it came on acutely with a catarrhal laryngitis and after a series of remissions became chronic. Even in the laryngoscope the picture may be apparently that of an ordinary chronic catarrhal affection. A tuberculous infiltration of the vocal cord may also deceptively simulate cancer. He has had several such cases in which no signs of tuberculosis could be detected elsewhere and the tuberculous nature of the process was distinguished only by microscopic examination of an excised scrap of the tumor. In 25 of his cases the cancer was differentiated in this way; in the others the disease was at a stage beyond all doubt. The excised scrap must be taken deep enough to be truly characteristic. In 2 there was both a cancer and a benign growth in the same throat. Seven of the 20 patients whose laryngeal cancer was removed by thyrotomy from 1 to 10 years ago are still living; another died of tuberculosis 4 years after the operation; another of gastric cancer after 8 years, and another of rectal cancer after 17 years. The proportion of permanent cures without local metastasis was thus 50 per cent. in the thyrotomy cases; 20 per cent. of the 5 cancers removed by the endolaryngeal route, and 20 per cent. of the 5 removed by total resection of the larynx. Thyrotomy may be regarded as an efficient means of curing cancer in the larynx if diagnosed early. The endolaryngeal route exposes too much to local recurrences later. In one of his cases the local recurrence did not develop until after an interval of 7 years, and the man is still living, 3 years later, but the growth is now inoperable. Age is no contraindication to thyrotomy. One of his patients was a man of 71 who is still in good health 4½ years after the thyrotomy.

LICHEN PLANUS SCLEROSUS ET ATROPHICUS (HALLOPEAU)

A REPORT OF SIX CASES (FIVE NEW) WITH A REVIEW OF THE LITERATURE*

OLIVER S. ORMSBY, M.D.
CHICAGO

The literature of this subject betrays some confusion as to what is meant by the term "lichen planus sclerosus et atrophicus."

Hallopeau first described this condition, named it "lichen planus atrophicus," and later added the word "sclerosus" to the title. Crocker added the word "morphæacus" on account of the resemblance in certain instances to morphea. That the disease resembles morphea to a marked degree is evidenced in the cases of Stowers, Allen, Schamburg, and others. These patients, when exhibited before dermatologic societies, were considered by some to be instances of lichen planus sclerosus et atrophicus, while others classed them as morphea.

There are some cases recorded under this title that appear to be of the ordinary lichen planus type, exhibiting subsequent atrophy of papules, leaving white atrophic spots. These are not examples of the type to be described here.

In 1887 Hallopeau¹ described the first case, and subsequently added three, one in 1889,² another in 1896,³ and a fourth in 1898.⁴ The histopathology of Hallopeau's first case was studied and reported by Darier; and subsequent observers have confirmed the original clinical and histologic descriptions of these two authors.

In 1892 Darier⁵ fully described a similar case of his own.

In 1900 Crocker⁶ transcribed notes taken by himself of a case presented by Marrant Baker before the London Dermatological Society, in 1882. In a chronologic order other recorded cases are the following: 1894, Brault⁷ and Pawlow;⁸ 1895, Gaucher, Barbe and Balli,⁹ and

Schwimmer¹⁰; 1896, Stowers,¹¹ Vinrace¹²; 1898, Vollmer¹³; 1899, Orbeck¹⁴; 1900, Zarubin¹⁵; 1903, Reiss,¹⁶ and Wechselmann¹⁷; 1905, Allen¹⁸; 1906, von Zumbusch¹⁹; 1907, Montgomery and Ormsby,²⁰ Schamburg²¹; 1909, Hoffman,²² Riecke,²³ Millian,²⁴ and Csillag.²⁵ The majority of the above cases are typical; the exceptions will be discussed later.

SYMPTOM-COMPLEX

The symptom-complex constituting the disorder as originally outlined by Hallopeau and confirmed by numerous observations since, includes the following:

The major portion of patients have been women varying in age from 30 to 63 years. They have usually been of nervous temperament. No other important fact has been demonstrated relative to the etiology. The sites of predilection are the upper portions of the trunk, about the breasts, over the clavicles, extending over the shoulders and downward over the upper part of the back, also the neck, axillæ, and forearms. Lesions also have been noted over the abdomen, on the thighs, about the vulva; and coincident lesions were noted by Hallopeau on the buccal mucosa, and in one case in this report, on the vaginal mucosa. The temple was affected in one of the atypical cases. (Dubreuilh and Petges).²⁶

The characteristic lesion is an irregular, often polygonal, flat-topped, white papule. In the case of Marrant Baker, some conical papules were noted. The white

color of lesions is striking and has been compared with that of ivory and mother-of-pearl. At times a distinct yellowish tinge is noted. The papules, as a rule, are firm to the touch, neither elevated nor depressed, but slight elevation may be present. They bend with the skin and when grouped may become wrinkled. As a rule, no areola is present, but at times a rosy or moderately pigmented zone surrounds the papule. They may be discrete or grouped and most cases present both types. When grouped to form plaques, the outline of the individual papules forming the plaques can be determined.

Each papule has on its shining, smooth surface from one to several (sometimes as many as twenty (Darier)) black or dark horny, comedo-like plugs, or minute pit-like depressions, which show the former site of the horny plugs. These elements are situated at the pilo-sebaceous or sweat-pore orifices, and are most important from the viewpoint of diagnosis. The wall of the pit-like depressions is of the same nature as the horny plug. The plaques vary in size up to several centimeters in diameter. They show on their surface the outlines of the primary papules containing the horny plugs, or exhibit minute depressions; and the whole plaque shows the peculiar shining white surface characteristic of the primary lesions. A linear arrangement of the papules

papillary and subpapillary layer of the corium. In general the resemblance in the histologic architecture between this condition and ordinary lichen planus is marked. The stratum corneum is thickened, as is also the stratum granulosum in most instances, while the rete is atrophied. The wavy line between the rete and the corium is straightened or obliterated. The entire upper portion of the corium shows marked collagenous hypertrophy. The collagen bundles are condensed and show less of the interlacing characteristics than usual. Very few connective tissue nuclei are present. The elastin is reduced in amount. A cellular infiltration is present, deeply in the corium, and moderately also about the vessels, glands and follicles. Horny plugs are described in the sweat-pores, extending into the ducts, and the latter show a condition of hyperkeratosis. Similar horny plugs have been described in connection with the pilo-sebaceous orifices.

From ordinary lichen planus this condition is distinguished by the presence of marked sclerosis in the upper part of the corium, and by deeper situation of the inflammatory process.

Fig. 1: Case 1.—Lichen planus sclerosus et atrophicus, showing discrete whitish papules and plaques with black horny points on the surface. Courtesy of Jour. Cutan. Dis.

is at times noted, similar to that seen in ordinary lichen ruber planus. There is, as a rule, no clinical sign of inflammation. The mode of development, as described by one of Hallopeau's patients, is as follows:

A black, horny point, surrounded by a bright red areola, is first noted. New and similar points occur which, after some months, unite; then the horny plug falls and the plaque becomes white.

My observations have not been similar, as I have seen new lesions developing, and the earliest manifestation consists of a minute white papule at the beginning, with either a dark spine or a pit on the surface.

The lesions, both papules and plaques, are persistent, but after a variable time, either from treatment or spontaneously, they undergo resolution and leave a delicate, smooth, white, soft, atrophic area of the size and shape of the original lesion, whether it be a discrete papule or a larger plaque. In one patient seen two years after complete involution of the lesions the atrophic scars were still present. The subjective sensations vary. Itching is the rule, but it is usually moderate in grade. A pulling or drawing sensation is described by some patients, while in others no subjective sensations are present.

HISTOPATHOLOGY

The changes described originally by Darier in Hallopeau's case have been confirmed by many observers. The most important change noted is a sclerosis of the

DIAGNOSIS

The important point in differential diagnosis is to distinguish this disorder from morphea guttata or circumscribed scleroderma. Vitiligo and nevus anemicus²⁷ would cause no confusion. The so-called "white-spot disease" should be mentioned, but as the cases of this disorder are most, if not all, examples of circumscribed scleroderma, no further comment is necessary. The irregular or angular, flat, shining, white papule, having on its surface dark, horny plugs or minute depressions, is characteristic of lichen planus sclerosus. Circumscribed scleroderma is not characterized by papules, and the horny plugs or punctate depressions are absent. These facts hold true for the most minute spots, as well as for large plaques. Lichen ruber planus with atrophy is distinguished by the presence of the ordinary red papules, and usually by severe itching, the latter, in the disorder under consideration, being slight or absent. There are no white papules, but merely atrophic white areas, which are secondary to a former inflammatory process.

27. Stein, R.: Ueber Naevus anemicus. Arch. f. Dermat. u. Syph., 1910, cl. 311. The author refers to the previously recorded cases of Vorner in 1906 and Fischer in 1909.

SUMMARY OF RECORDED CASES

The majority of cases mentioned earlier in this article are pure examples of the Hallopeau type. A few only will be briefly discussed.

Von Zumbusch's case of "lichen albus" is classed here as belonging to the Hallopeau type.

Csillag's case of *dermatitis lichenoides chronica atrophicus* probably belongs here, as does also Millian's case of lichen planus atrophicus, for which he thought the best title would be "leukoderma with punctate atrophy."

Riecke's case of provisional "white-spot disease" practically fulfils the requirements of this group. On the other hand, the case of Dubrenilh and Petges (lichen planus atrophicus), that of Gaucher, Barbe and Balli (lichen planus atrophicus et pigmentosus), and that of Wechselmann, of atrophodermia erythematosa maculosa (lichen planus atrophicus), and Pringle's case (annular and atrophic lichen planus), are examples of lichen ruber planus associated with cutaneous atrophy.

The case of von Zumbusch, described by him as a new disorder and termed "lichen albus," clearly belongs to

symptoms aside from some drawing sensations, and no ordinary lichen planus papules.

In the discussion of this case Darier stated that the disorder could be classed in one of four categories: lichen planus sclerosus, white-spot disease, "scleroderma en carte de visite" of Unna, or lichen albus. It appears, therefore, reasonable to place it in the group under discussion.

The most interesting report of all recent ones is that of Riecke. He gives a careful clinical and histologic analysis of a case, critically surveys the literature on the subject and finally places his case provisionally with two others—those of Westburg²⁹ and Johnston and Sherwell³⁰—under the title of "white-spot disease." On account of the very close resemblance to lichen planus

Fig. 3.; Case 1.—Lichen planus sclerosus et atrophicus. Showing a higher magnification of one area shown in Figures 1 and 2.

this group. The clinical picture and histologic findings were later reviewed by Hallopeau,²⁸ who believed that it should be classed as a case of lichen planus sclerosus.

Under the title "dermatitis lichenoides chronica atrophicus" Csillag describes a case which he classes as analogous with von Zumbusch's lichen albus. The clinical description of the lesions in this patient correspond in many particulars to those found in the cases of the subject under discussion, and is, therefore, placed provisionally in this group. Pale red mixed with chalky-white small areas and large plaques are described, on the surface of which are horny plugs connected with the pilo-sebaceous openings. The plate used for illustration is less characteristic than the written description.

Millian describes a case under the title "lichen planus atrophicus," or, better, "leukoderma with punctate atrophy," in which pin-head to pea-sized white lesions occurred. These were circular, shining, depressed, and showed a central punctate opening, as though they had been pricked with a pin. The large plaques were white, waxy and scaling. The earliest lesions did not present the punctate depressions. There were no subjective

Fig. 4.—Lichen ruber planus with associated subsequent atrophic whitish areas. Shown for comparison with lichen planus sclerosus.

sclerosus of his clinical and histologic description, as well as the plate used for illustration of the case, a brief abstract follows:

The patient was a woman, 50 years of age. The cutaneous disorder began ten years before with a lesion the size of a silver quarter over the pit of the stomach, preceded by itching. The lesions had extended rapidly during the previous year. On examination the following was noted: The lesions were located chiefly on the abdomen from the pit of the stomach to the inguinal folds with a few on the outer surface of the thighs. They were sago-grain to lentil-sized, well-defined, round, oval, irregular, and polygonal in shape, with many closely set and confluent plaques, largely on a level with the cutaneous surface. The smaller were slightly elevated, but,

²⁸ Hallopeau: The Nature of Lichen Albus of von Zumbusch. Bull. de la Soc. Française d. dermat., 1907-08, p. 109.

²⁹ Westburg: Monatsh. f. prakt. Dermat., 1901, xxxiii, p. 355.
³⁰ Johnston and Sherwell: Jour. Cutan. Dis., 1903, xxi, 302.

on the whole, they were neither elevated nor depressed. They were not palpable and presented a markedly white luster. Each had a central punctate depression resembling a comedo. The smaller were smooth and showed no sign of inflammation. In the center of an older area some color, red or reddish-brown, was noted. In some areas a thin brownish-red crust covered the lesion, but, as a rule, this was surrounded by an alabaster-white ring. In some of the areas was a white lesion surrounded by a red halo. By confluence nail-sized plaques were formed.

Histologically, the stratum corneum was thickened; the rete thinner than normal, and the wavy line between the epidermis and the corium was largely obliterated. The connective tissue of the corium was increased in amount and presented few nuclei in its bundles. A cellular infiltration was noted deeply and at the periphery of the area. Vacuoles and lacunae were noted between the corium and epidermis, which the author deemed an important finding. The elastin that was present was normal. Horny masses were present in the hair follicles, extending as far as the sebaceous gland opening.

The case of lichen planus atrophicus described by Dubreuilh and Petges is not of the type under discussion. The lesions were situated chiefly on the forehead, in the scalp, and later in the mouth. During the course of the disease the question of diagnosis was uncertain for some time. Lupus erythematosus, syphilis and scleroderma en plaque were considered. Finally, after the mouth lesions were discovered, the diagnosis above

Fig. 5.—Morphea guttata resembling lichen planus sclerosus et atrophicus. Back view of a patient who had diffuse scleroderma of the lower limbs. Reported in *Jour. Cutan. Dis.*, 1907.

named was made. The case apparently was one of anomalous lichen planus associated with cutaneous atrophy.

The case of lichen planus atrophicus et pigmentosus of Gauchér, Barbe and Balli does not belong to this group. This patient exhibited highly-colored pruritic papules and plaques associated with marked hyperpigmentation, and, finally, atrophy. When the case was discussed before the French Dermatologic Society, Darier, who was familiar with the Hallopeau type, was of the opinion that the case was not one of lichen planus sclerosus.

Wechselmann, in 1903, reported a case under the title "lichen planus atrophicus." This case was further described with detailed histologic study, in 1904, under the title "atrophoderma erythematosum maculosum (lichen planus atrophicus)." The patient was a man, 35 years of age, with cutaneous lesions situated on the forehead, in front of the left ear, over the mastoid region, in the hairy scalp, and on the back to the left of the spinous processes near the junction of the first thoracic vertebra. In the last-named region, bluish-red, umbilicated, ordinary lichen planus papules were described. In the regions about the temple, ear, and scalp, erythematous and papular lesions, forming patches, occurred, which later underwent atrophy. The histology is that of lichen

planus with atrophy. No white papules were described, and the case clinically, as well as histologically, is not properly of the Hallopeau type, but appears rather to belong to the group in which atrophy was a sequence.

Pringle³¹ exhibited a case of annular and atrophic lichen planus before the London Dermatologic Society in May, 1901. This was an example of ordinary lichen planus with atrophy.

Figure 4 illustrates a case of lichen ruber planus associated with circumscribed atrophic white areas. The case is cited merely for comparison.

The six cases recorded here occurred in the practice of Dr. James Nevins Hyde, the late Dr. Frank Hugh Montgomery and myself. Case 1 is reproduced from a report³² made in 1907, for the reason that a microscopic study was made in that case. In the five new ones only clinical observations are available.

CASE REPORTS

CASE 1.—Patient consulted me at the West Side Hospital (dermatologic clinic), in January, 1906. "The patient, a woman, aged 56, was born and reared in Germany, but has lived in Chicago for thirteen years. She has had seven pregnancies, three of which terminated prematurely. In two others, the infants lived only a few hours, and the remaining two are represented now by two healthy children, aged 23 and 25 years respectively. She gives a history of having suffered many times during her life with a vague febrile disorder she called 'malaria.' She is very heavy, somewhat pallid, but fairly well nourished, and is excessively nervous.

"The present skin disorder began about eight months ago, she states, as small white and black spots, which have gradually increased in number. The lesions are now situated chiefly over the back part of the shoulders, but extend toward the neck and also a short distance down the back. A few spots are scattered over the upper part of the chest down to the margin of the mammae, and there are a few lesions on the upper and external aspect of the arm.

"The primary lesion is apparently a slightly elevated, angular, polygonal or irregularly-shaped, white papule, which on attaining the size of a millet-seed shows on its surface one or several small, elevated, black, comedo-like points, or minute depressions, where the black points formerly existed. A lesion of the size of a split pea usually contains five or six such points or depressions. The papules vary in size from that of a pin-head to that of a split pea. A few very minute, angular, white papules are present. Some of the lesions are surrounded by a narrow, pinkish areola; others by a brownish discoloration; while many present no color changes at the border.

"Over the back part of each shoulder is a patch formed by the coalescence of papules which, however, do not completely lose their identity. One of these patches measures about two inches in diameter, is irregular in outline, slightly elevated, white in color except for the black points and depressions which dot its surface, rough to the touch, and presents a somewhat wrinkled appearance (Figs. 1, 2 and 3). Over the upper part of the chest the lesions are discrete, irregularly disseminated and abundant. Over the clavicles a somewhat linear arrangement is apparent; while in other areas there is some grouping of the lesions. Here and there atrophic, slightly depressed lesions are present, which are of the shape and color of those just described.

"During the two months in which she has been under observation, there have been displayed at times a very few small, red- or brown-tinged papules, which were indistinguishable from the lesions of ordinary lichen planus, but their transformation into white papules could not be traced. During this period the patient has had very simple treatment, and the only change noted is the disappearance of most of the small, elevated, black points, their places now being occupied by the depressions. She complains of no subjective sensations except,

31. Pringle: A Case of Annular and Atrophic Lichen Planus, *Brit. Jour. Dermat.*, 1901, III, 215.

32. *Jour. Cutan. Dis.*, xxv, 1.

as the patient describes it, that of 'pulling.' There are no lesions in the mouth or about the wrists.

"Histology.—A biopsy was performed, removing a split pea-sized lesion from the posterior aspect of the left shoulder. This lesion was typical and exhibited on its surface six small dots or depressions, from which the comedone-like plugs had been removed. The tissue was fixed and hardened in alcohol, embedded in paraffin, and stained in various ways. A series of sections in which two hair follicles occurred were studied. A lanugo hair was present in each follicle. The most marked changes are in and about these follicles. As a whole, collagen and elastin are abundantly present, except in the areas of cellular infiltration, where both are either lessened or absent. Aside from the special areas to be described, the collagen appears condensed and contains fewer connective tissue nuclei than normal. Blood-vessels are few and are represented by strings of cells running horizontally across the field or radiating in various ways from the hair follicles. No vessels can be demonstrated in the papillary layer. In these sections three distinct and fairly well defined masses of cellular infiltration are present, in addition to that surrounding the follicles. They are situated in the lower part of the corium, about parallel with the base of the follicles, but not in connection with these structures. Beside these deposits, some small areas and some single cells are irregularly distributed about the corium. The infiltration is composed of connective tissue cells, lymphocytes, or small plasma cells, and mast cells. The latter are unusually abundant and occur not only in these special areas, but also irregularly throughout the corium. They are of various shapes, some large with their granules extending far from the nucleus. The changes in the epidermis occur chiefly about the follicular openings. The line between the epidermis and the corium is fairly well defined, its wavy character being only in places obliterated. The rete Malpighii consists of about eight rows of cells, in which there is some increase in the pigment. The stratum granulosum is composed of two rows of elongated, flattened cells containing fine granules of keratohyaline material. The stratum lucidum is not demonstrable, and the stratum corneum is thickened. The mouths of the two follicles, above mentioned, are widely dilated, and in the section present the appearance of a deep v-shaped opening, extending from the surface into the follicle. In places in the different sections a part of this large opening is occupied by a horny material similar to the stratum corneum. The lanugo hair can be demonstrated in the center of this opening, extending down to the base of the follicle. No sweat-ducts or pores occur in the sections, making it impossible to determine a connection between these structures and the clinical pits or depressions. The coil glands present are unaffected. In one place is a circumscribed area of cellular infiltration in the corium between a coil gland below and the epidermis above, but it seems to have no relation to the gland or its duct. From the involvement of the pilo-sebaceous apparatus in such a pathologic process it would seem that this is the seat of the original comedone-like plug, and, later, the pit or depression. The pathologic process is more deeply situated than in ordinary lichen planus and the marked involvement of the follicles is not usual in the common variety."

CASE 2.—A private patient of Dr. Hyde's, seen Oct. 15, 1906, and under observation for about two and a half years, was 49 years of age, weighed 176 pounds, and was not robust. The family history revealed no important facts. For years the patient had been nervous and slept poorly. She had suffered from variola at 5 years of age and had in addition the usual diseases incident to childhood. For twenty years she suffered from pruritus each summer, chiefly on the lower limbs. The cutaneous disorder began five years before, on the wrists and thighs. Six months before new lesions occurred about the vulva, accompanied by severe itching, and it was this that induced the patient to seek relief.

An examination on Oct. 15, 1906, showed, on the flexor surfaces of each wrist, many dense, white, irregular papules, varying in size, also some larger plaques. The former were poppy-seed to pea-sized; the latter somewhat larger than a coffee-bean. The inner faces of the thighs showed several round, oval or irregular areas, sharply defined, white or pale red, with

a slightly depressed and atrophic center, the border being narrow and irregular, and consisting of small, dense, white, irregular papules. The surface of these lesions was shining and showed punctate depressions. A few scattered lesions were present over the abdomen, about the groins, and over the legs and arms. Some traumatic lesions were also present in these latter areas. On the mucous membrane of the vagina, especially about the clitoris, was a characteristic lichen planus infiltration.

Six months later the patient developed diabetes mellitus, which was still present when she was last seen. In April, 1909, there was a marked recurrence of the pruritus vulvæ, at which time typical lesions of lichen planus sclerosus in various stages of involution were present. A period of radio-therapeutic treatment was given in April and May, since which time the patient remained comfortable.

CASE 3.—The patient consulted my late colleague, Dr. Montgomery, May 31, 1907, from whose notes the following is taken:

The patient, Mrs. M. B., aged 33, had been a delicate, nervous child, but had had no serious illness except scarlet fever from which she had made a good recovery. After finishing a high-school course, she studied and later practiced law five years. Ten years before, while studying, she noticed the first signs

Fig. 6.—Morphea guttata closely resembling lichen planus sclerosus et atrophicus (front view).

of the present skin disorder, which appeared as small white spots over the posterior surface of the shoulders. They were white in the beginning and had never been productive of any subjective sensations. They persisted with little or no change except to become somewhat more depressed. Six or eight months before this visit she noticed new areas coming on the back of the neck in the median line extending into the occiput. About one month later lesions began to appear over the breasts and on either thigh. After another month a small area appeared on the anterior surface of the neck (left side), and for about a month lesions appeared on the anterior surface of both wrists. On examination, an irregular triangular area on the back of the neck was typical of lichen planus sclerosus et atrophicus. Not only were the normal lines and folds of the skin exaggerated, but quite typical sclerotic lichen planus papules were visible. A number of these showed characteristic black points. The older lesions on the shoulders exhibited slightly depressed atrophic areas covered with parchment-like epidermis. They were white, but had a slightly dirty-yellowish tinge. On the anterior surface of the neck were a few papules, some with black points, and some showing atrophic areas. Two irregular areas about 2½ inches in diameter were situated on the outer surface of either hip, made up of minute atrophic points, some of which were distinctly angular in outline. On the anterior surface of each wrist were three or four pin-head-sized and smaller, whitish papules. Some of them had the appearance of being beneath the skin. These had been there about a month. Just above

each nipple was an irregular area about $1\frac{1}{2}$ inches in diameter made up of quite closely aggregated, clear, white, very slight depressed (?) atrophic points. In this plaque individual lesions retained their identity. No depression or change in texture could be detected with the finger. The patient and her husband (a physician) were positive that there had been no preceding changes of a different character, and that the patches enlarged simply by the appearance of new white points of the same character. Dermographism was marked and had been present for about a year. A report after seven months indicated no change in the existing, and no appearance of new, lesions.

CASE 4.—The patient, a woman aged 67, consulted Dr. Montgomery Oct. 16, 1907. No notes were made concerning the family history. Her general health was fair. She passed the climacteric period at the age of 45. She was of a markedly neurotic disposition. Her skin showed evidences of senility, being thin, atrophic, with patches of hyperpigmentation, and areas of keratosis. The cutaneous disorder was of five years' duration, and had been treated in Hanover, Germany. The patient had also consulted Professor Lassar, of Berlin.

The lesions were situated on the front and back of each shoulder and on the neck with a few outlying papules over the chest. The greater number of lesions were irregular white papules, level with the skin, on the surface of which were

Fig. 7.—Morphea guttata. Same patient as represented in Figure 6 (back view).

minute black points. There were also several typical atrophic areas where lesions had undergone resolution. Slight telangiectasia was noted in the region of some lesions, which varied in size from 2 to 4 mm. Early in the history of the disorder itching was quite marked; later it became less and at the time of the examination was present only to a slight degree. Six months after the first examination there was not much change in most of the lesions. The area on the right shoulder had increased in size. At this time a general examination revealed an interstitial nephritis, with albumin and casts in the urine and blood-pressure of 230. In addition to topical applications, radiotherapy was employed. In March, 1910, I again examined the patient, when only the relics of the lichen planus sclerosus lesions remained. The last consultation was made with reference to the facial hyperpigmentations.

CASE 5.—The patient consulted me, Aug. 11, 1909. This patient was a refined, rather delicate woman, 42 years of age. Aside from her nervous temperament, no facts of importance relative to the family or past history were obtained. The cutaneous disorder was of fourteen months' duration. It began on the right side over the region of the clavicle, with six to eight pin-head-sized whitish papules. New lesions gradually developed over the shoulder and upper part of the back, and over the opposite clavicle, shoulder, and back, and a few sparsely distributed over the abdomen. On examination, indi-

vidual, discrete, irregular, flat-topped, hard white papules, each presenting two to five dark, horny elevations on its surface, and in some only pit-like depressions, were noted in all the described areas. In addition, several dime-sized areas, especially over the shoulders, displayed characteristic grouping of the papules. In these areas individual papules could be detected. The surface was whitish, except where dotted with horny plugs or dark minute pit-like depressions. Radiotherapy was employed during September, 1909. In December, the lesions had largely undergone resolution. In April, 1910, two new plaques developed. In this patient no areola was ever present and no lesions suggesting lichen ruber planus. There was no vascular element in the case, and no mucous membrane involvement. The lesions were sclerotic and whitish from the minutest earliest to the older, forming plaques, each showing characteristic dark points.

CASE 6.—The patient first appeared at the dermatologic clinic of Rush Medical College, where she was seen by Dr. Anthony, through whose courtesy I saw her. This patient was the youngest of the group, being 30 years of age. She was seen first on Aug. 17, 1909. She was a telephone operator, highly nervous, had suffered for a long period with severe headaches, and frequent attacks of palpitation of the heart. She was not robust. Her hands and feet were habitually cold. The urine was normal, though she was annoyed by frequent urination. She was practically neurasthenic.

The cutaneous disorder was of one and a half years' duration, and was nearly a replica of Case 5 of this series. The lesions were situated over the clavicles on each side, and extended from over the shoulders to the upper part of the back. The same white sclerosed papules, discrete and grouped, all containing dark horny spines or minute horny depressions, were present. There were no red papules, none of the lesions had an areola, and there were no mucous membrane lesions.

This patient was demonstrated with Case 5 at a meeting of the Chicago Dermatological Society in December, 1909, at which several members of the American Dermatological Association were present.

In February, 1910, radiotherapy was used, with beneficial results.

SUMMARY OF THE SIX CASES HERE RECORDED

All the patients were women, aged 30, 33, 42, 51, 51 and 63 years, respectively. All were neurotic. One had neurasthenia; another had marked, peculiar psychic phenomena; diabetes was present in one; interstitial nephritis in a second. The duration of the cutaneous disease was eight months, fourteen months, eighteen months, five years, five years and ten years, respectively.

The site of most extensive involvement in five of the patients was the region over the clavicles, shoulders, neck and upper part of the back. In one the wrists, flexor surface, thighs, abdomen, groins, were chiefly affected, with a few lesions appearing on the legs and arms. The essential lesions in all cases were whitish, discrete, round, oval, irregular, or polygonal, flat-topped papules; similar lesions forming whitish plaques, all having dark, horny spines, or punctate depressions. The lesions were either level with the surrounding cutaneous surface or very slightly elevated. In all the terminal result was a white depressed, delicate scarring or production of atrophic areas of the size and shape of the preceding lesion, whether papule or plaque.

In two patients a few usual reddish lichen ruber planus papules were present, but they were never observed undergoing transformation into the white lesions. The latter were from the beginning white papules.

In one patient coincident mucous membrane involvement with ordinary lichen planus was noted. In Hallopeau's case this occurred in the mouth. In one of my cases the vagina was involved. In five cases subjective sensations were slight or absent; in one they were

marked, but the pruritus could not be attributed to the disorder under discussion.

That the disease may be persistent is evidenced by its long duration in some of the patients who still exhibit active lesions.

In five cases in which radiotherapy was used it proved to be a valuable therapeutic measure.

The group as a whole corresponds clinically with the Hallopeau type of lichen planus sclerosus, and in the one case where a histological study was made it corresponded with Darier's observations in Hallopeau's case, and also with his own.

CONCLUSIONS

From the brief summary detailed above it appears logical to group the six cases under one title. They do not differ from one another more than the members of any group of six different patients suffering with any single dermatosis. In the question of differential diagnosis only three cutaneous disorders capable of producing whitish lesions on the skin need be considered, viz.: localized or circumscribed scleroderma (Fig. 5), lichen ruber planus of usual type associated with or followed by atrophy, and the so-called "white-spot disease." Such disorders as vitiligo, syphilis, lupus erythematosus, nævus anæmicus, and lepra are readily excluded. Lichen planus of the usual type associated with atrophy is excluded by the fact that the primary lesion in these cases is never reddish, as in its whole career it is a whitish sclerotic papule. That these cases are probably of the same nature and simply a special form of lichen planus is strongly suggested by the association in certain cases with mucous membrane involvement of the lichen planus type; also by the fact that some papules of the ordinary form at times concur, and, finally, by the fact that the lesions themselves, both as to size, shape and arrangement, are similar, the striking difference existing only in the color and presence of characteristic dark, horny spines and keratotic punctiform depressions. The so-called "white-spot disease," as a rule, if not always, is an anomalous localized scleroderma. In certain cases of circumscribed scleroderma the resemblance is striking (Figs. 6 and 7). Here again the initial papule is the important factor. In the case of circumscribed scleroderma above referred to papulation is simulated by the line of cleavage in the skin, but on careful observation the difference can be noted, and in scleroderma involvement of the sweat-pore and pilo-sebaceous follicles is wanting. Finally, in a retrospect of the entire subject the identity of lichen planus sclerosus appears established, but the separate existence of a "white-spot disease" requires further study.

106 State Street.

Imprisonment of a Physician for Extortion.—Our German exchanges state that a certain sickness insurance society refused to pay the account rendered by a local physician on the ground of the statute of time limitations. He warned the company that unless they paid the account he would bring the matter to the attention of the local medical council and the company would be boycotted. The government experts, the *königl. Medicinalkollegium*, declared the charges too high and the company thereupon sued the physician for attempted extortion, and he was condemned by the local court to a week's imprisonment. The editorial comment in one exchange is merely a warning to physicians to proceed always with extreme conscientiousness and prudence in attempting to collect what is due them.

REPORT OF A CASE OF INTUSSUSCEPTION

A. L. SHARBER, M.D.
NASHVILLE, TENN.

In presenting the following case of intussusception which came under my care, I wish to call attention to its most unusual phases, which were of great interest to me and to those of my colleagues who saw the operations.

Patient.—On April 1, 1910, I was called to see I. H., white, aged 21, a dairyman, single, with family history as follows: Mother living and widow; father died at age of 81, of senility; one brother living, married and in good health. Two sisters living, one married, one single, both enjoying good health. No history of tuberculosis, cancer, rheumatism, heart, kidney or nervous trouble. The patient used no tobacco or spirits; drank coffee three times a day; at times drank quantities of tea. Habits regular, except constipation. He had had most diseases of childhood; had never had diphtheria, scarlet or typhoid fever, pneumonia, kidney or heart trouble. Genitourinary examination was negative. He had had chronic indigestion with acute exacerbations, which would last two or three days, with slight pain at times in the epigastrium, accompanied by nausea and some vomiting.

Present Illness.—When, on April 1, 1910, I saw patient for the first time his pulse, temperature and respiration were prac-

Fig. 1.—Intussusception first: section of ileum 3 feet long, removed April 4, 1910. Forceps at neck of intussusception.

tically normal. He complained of some pain in the epigastrium and nausea, and there was slight vomiting of bile-colored matter. His tongue was coated. I ordered 3 gr. of calomel, followed next morning with magnesium sulphate. I withheld all food. The patient had two bowel actions in afternoon and night, and following morning was comfortable and ate breakfast. I learned from the attendants that the magnesium sulphate was not given. A comfortable day and night followed. On Sunday forenoon, April 3, I received a message saying that the patient was suffering with pain in stomach and was vomiting. I saw patient about 1 o'clock the same day and found that he was vomiting incessantly. There was continuous pain in the upper part of the abdomen. I had him wash his stomach out with a solution of bicarbonate of soda and left orders for an enema, which was given and returned with slight result. The nausea was somewhat relieved, but vomiting soon set up again, and the pain was continuous. The abdomen at this time was soft, with no distention and no evidence of tumor present. I saw patient again at 7 o'clock that night and found the symptoms greatly exaggerated. There was still no distention, but I felt a tumor below and to the right of umbilicus, with a dullness that extended almost across the lower half of abdomen. I gave an enema, with no result; then gave one-half grain of morphin and advised sending the patient to a hospital. I told the family that I believed an operation to be imperative, but would do what I could to relieve obstruction before resorting to operation. This was done. During the night the patient was given laparotomy enemas, enemas of alum, etc., but with no result.

He passed some blood and mucus (just before operation, slight) and in the early morning vomited some fecal matter.

First Operation.—The patient was prepared and operated on April 4. I made a median incision below the umbilicus which extended above and to the left of that point, and found an invaginated small intestine which I supposed to be the upper part of the ileum. I resected the intussuscepted intestine, which was more or less gangrenous, taking out three feet. I did an end-to-end approximation and closed the abdomen in the usual way, leaving drain in.

The patient suffered very little shock and was put to bed in Fowler's position and given Murphy enteroclyses. He rested well. During the first forty-eight hours the pulse was frequent, as rapid as 120 per minute at times; temperature from 99 to 101; but on the third day, while the temperature was still slightly elevated, the pulse returned to normal. On the second day the patient had some nausea and vomiting. His stomach was lavaged, which relieved the vomiting entirely, and nausea did not return until the third day, at which time lavage was repeated and his stomach symptoms were relieved entirely. His kidneys acted freely, and on the fourth day, April 7, he had a voluntary bowel movement. His condition and recovery were entirely satisfactory until April 14, at which time he had some nausea, but did not vomit until next day. At this time he had been taking nourishment by mouth for five days. The vomiting was somewhat relieved by lavage, but his condition grew worse and we decided on another operation that morning at 8 o'clock. This was April 15.

Fig. 2.—Intussusception second; section of jejunum $4\frac{1}{2}$ feet long, removed April 24, 1910. Forceps at point where neck of intussusception was, before intestine was opened.

Second Operation.—Incision was made in median line above umbilicus, and I found that I had to extend this into upper part of old incision in order to reach the obstructed parts. I found an adhesive band about eighteen inches from the resected portion of the bowel. The omentum was adherent to several structures, but doing no harm. The resected portion was free from adhesions and perfectly healed. I freed the adhesive band, sutured over the raw surfaces, and closed the abdomen.

With little or no shock from this second operation the patient was again put to bed in Fowler's position with Murphy drip. Condition was satisfactory, except for nausea and vomiting, which were relieved, as before, by lavage. On April 17, the third day after second operation, he was given magnesium sulphate through stomach-tube, which resulted in three or four stools. On the fifth day he was taking nourishment, and on the eighth, light diet. On April 23, the ninth day after second operation, he had slight nausea and refused nourishment. He complained of some pain in abdomen in forenoon, but later on in the afternoon the pain became severe and continuous. There was persistent vomiting and early shock. I also found a tumor in left upper quadrant of the abdomen with dulness, extreme tenderness and very slight distention.

Third Operation.—We operated at 1:30 o'clock a. m. April 24. I made incision in the left semilunar line and delivered the invaginated intestine, which was very congested and edematous,

almost as much so as the first resected portion. I resected about $4\frac{1}{2}$ or 5 feet of jejunum and found a tumor of the adenopapillomatous variety at the neck of and termination of the invagination; also two or three small ones projecting from the lumen of the intestine. The tumors were examined by Dr. Newton Evans, who reported their nature to be as stated. These tumors were almost large enough to obstruct the lumen. As before, I made an end-to-end approximation and closed the incision with a drain the lower end.

Postoperative History.—After operation patient was put to bed with foot of bed elevated and was given hypodermoclyses, with slight stimulation, strychnin, digitalin and adrenalin; also Murphy drip. The patient suffered considerable shock after this, the third major operation he had undergone within three weeks. He made an uneventful recovery. There was slight infection, though the wounds healed kindly. On May 16 he was up and walking about the hospital.

After the specimen had been removed and placed in saline solution slight peristalsis of portions was observed for several minutes.

The interesting points of the case are the following:

- 1.—Age of patient, 21 years.
- 2.—History of indigestion for two or three years.

Fig. 3.—Abdomen after wounds had healed, with median and lateral scars.

- 3.—Onset of attacks.
- 4.—Early diagnosis.
- 5.—Early surgical interference.
- 6.—Recurrent attacks.
- 7.—Rapid recovery from each operation.
- 8.—At times active peristalsis.
- 9.—Large quantities of liquids administered by enteroclysis retained over great length of time.

The enteroclyses were as follows: After the first operation, $1\frac{1}{2}$ pints of saline solution, every four hours for four days, all retained. After the second operation, $1\frac{1}{2}$ pints of saline solution, and $1\frac{1}{2}$ ounces of a pre-digested food, every four hours for two days, all retained but part of one. After the third operation, $1\frac{1}{2}$ pints of saline solution, $1\frac{1}{2}$ ounces of the alcoholic pre-digested food, every four hours for two days; part of one returned. The quantity was then diminished to 4 ounces of saline solution and 1 ounce of the peptonized food, every four hours for twenty days; all retained. The reason for the long-continued enteroclyses was that patient refused to take proper nourishment and liquids.

140 Eighth Avenue North.

THE DIAGNOSIS OF LEPROSY*

ISADORE DYER, Ph.B., M.D.

Professor on Diseases of the Skin, Medical Department, Tulane
University of Louisiana; Consulting Leprologist to
the Louisiana Leper Home, etc.

AND

RALPH HOPKINS, M.D.

Lecturer on Diseases of the Skin, Medical Department, Tulane
University of Louisiana; Visiting Physician to
the Louisiana Leper Home

NEW ORLEANS

Long association with the Louisiana Leper Home has given us an opportunity for the observation of leprosy, and we hope that this, together with the importance of correct and early diagnosis, in countries where leprosy is likely to occur, will justify the present discussion of this subject. We are not submitting any new points in diagnosis but rather argue the need of a practical presentation of the matter for the general profession, especially in our own country, where every now and then a notable case proves an ignorance of essential points which should be known. More than this, the reports of imported cases of leprosy in our seaport cities have shown conclusively either that the national quarantine against leprosy is a farce in its enforcement, or that the quarantine officials are ignorant of the symptoms of the disease. In New York chiefly numerous cases have been presented which have more or less recently been admitted to this country without hindrance.

As a matter of fact, the increasing number of lepers in New York has grown by importation, as the disease so far is not held endemic there.

The trouble in diagnosis lies more with atypical cases, with incipient tubercular cases and with those anesthetic cases which present no longer active skin manifestations. Another source of confusion in diagnosis lies in the changes that appear in lesions during the periodic occurrence of exacerbations accompanied by lepra fever.

Like syphilis, leprosy has often been divided into stages and types, but, as in syphilis the value of such diagrammatic classification of leprosy is greatly impaired by the fact that the types are often mixed and that the lesions that should be present in one stage are often found in another. Generally the type depends on the habitat of the bacillary cause, the anesthetic or trophic being due to nervous injury by the bacilli, the tubercular or nodular being due to the presence of the bacilli in the skin, and the mixed type being a combination of the anesthetic and tubercular forms. It is not unusual in the course of years to see a change in the type. The tubercular type in a mixed case may disappear, leaving only the anesthetic, and a purely anesthetic case may after years develop tubercles, forming the mixed type, which may in turn evolve a trophic type, having no tubercles in evidence.

The usual sequence of the lesions after the prodromal period is that the first manifestation in almost every case is in macules which usually initiate all types, usually varying in their location accordingly. Much rarer is the bullous eruption which occurs in this same early stage. Tubercles usually appear later than macules and may be independent of them; the ulceration and cicatrization of the skin occur ordinarily only in the terminal stage, though the perforating ulcer, which is a sinus leading to necrotic bone, may be found early, and in mutilating types the erosions following bullous lep-

rosy may form true ulcers before any macules or tubercles present themselves.

The macular eruptions do not always present the same characteristics. They vary from the size of a dollar, or smaller, to a patch large enough to cover an entire anatomic region; the pigment may be almost uniformly distributed throughout the patch, as it is in chloasma, or it may disappear in the center, leaving a ring of pigment surrounding an area of skin lighter in color than the normal; somewhat the same arrangement that ringworm of the general surface assumes, except that the atrophy of pigment in the center is marked and may, at the same time, involve the deeper skin. Scales are unusual in both types and occur usually only as a result of inflammation in the area or as the evidence of trophic disturbances.

The first type, the uniformly pigmented macule, depends largely for its characteristics on the amount of infiltration provoked by the presence of the bacilli. It may be simply a brown stain, level with the surface of the skin, with an irregularly shaped border not always margined, or a patch so elevated that the term macule becomes a misnomer. On the other hand, there may be multitudinous macules, with symmetrically bilateral distribution on the trunk and extremities alike, entirely free of bacilli and having all the characteristics of a true erythema.

This form of macule is particularly common in anesthetic leprosy in which the early involvement of the nerve trunks of the extremities points to the toxic influence of the leprous deposits along the nerves. This is particularly argued in the facts that such eruptions of macules are evanescent and that the lesions themselves are highly colored, bright red, and are often apt to be hyperesthetic and not anesthetic as are the more deeply pigmented and infiltrated lesions.

In the second form the margin is well defined and the brown color becomes a purplish red. Between these two extremes are the variations in shade made possible by the varying degrees of inflammatory infiltration. The favorite location is the buttocks, though the face, trunk and limbs may also be involved, and these macules are often the sites of later tubercles or nodules, especially when found on the face. Though these may not be necessarily symmetrical when they first appear, later these macules become so as the eruption fully develops. During the periods of lepra fever the macules may become intensely inflamed and painful, and though the fever does not usually occur severely during the incipient period, we have had at the Louisiana Leper Home instances in which the whole macular areas, numbering four or five as large as the palm of a child's hand, have ulcerated. Ulceration in the incipient stage is indeed rare, and can be explained only by the lepra fever, which is evidently a manifestation in greater or less degree of culmination of deposits of lepra organism, or else the acute reaction associated with new fields of invasion.

In the circinate type the patch of lepra macules usually grows in size after it first appears, spreading from the outer border of the ring, which preserves a well-defined margin; and it is more often associated with the anesthetic than the tubercular form. The inner margin of the ring is not liable to show as well-defined a border as the outer, and as the lesion grows larger in area the paler center grows also, keeping the pigmented ring nearly constant in relative breadth. The degree of infiltration in this type of macule is not as variable as in the first type, usually remaining slight, and the color varies with the depth of infiltration. This,

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

too, is found almost always as a light brown, aptly described as *café au lait*, which is the characteristic color of all of the macules that present the least amount of infiltration. A reddish tinge is added to the brown of the border in those cases with more marked infiltration, the resultant color being a red-brown, which is again intensified during the lepra fever. This circinate type may occur on any part of the body, but the hands and head are not as liable to this as to the form in which the macule presents a uniformly pigmented area, appearing *en plaque*. The areas of especial predilection are the shoulders, legs, thighs, buttocks and forearms, in the order named. It is not infrequent to find confluent lesions of this type forming grotesque ribbons of irregular borders and outlines, extending along the whole of an extremity or showing symmetric figures over the back.

The bullous eruption, which is very rarely seen, occurs associated with this early stage, or precedes the macule if it occurs at all. The bullæ contain serum at first, but become pustular in a short time. They are not larger than a small marble, and occur most frequently on the hands and feet. The clinical diagnosis is frequently difficult without other evidences of the disease. The bullæ have a predilection for the areas over the knuckles of the fingers and will repeatedly appear in the same site, establishing scar areas with encircling pigment, which is characteristic. Often these lesions lead to ulceration and even trophic changes in many cases misleading to a diagnosis of neuritis and not infrequently escaping the suspicion of leprosy for months or years, in the hands of neurologists. Several cases have finally come to a diagnosis of leprosy when the skin evidences of macules or tubercles elsewhere have developed.

On the feet the bullæ seldom appear so early, and when they do come they are found on the plantar surface, usually going on to actual ulceration, trophic in character.

Late leprosy will develop bullæ as evidences of trophic changes and here the destruction of skin and deeper tissues is the rule, finally causing the destructive, amputative deformities found in nerve leprosy and the loss of terminal or intermediate phalanges of the digits of fingers and toes.

The tubercles in leprosy have their favorite location on the face, involving especially the lower part of the forehead, the ears, the nose, the chin, the cheeks, in the order named. The hands and other parts are less frequently involved.

They may begin in the patches of a macular eruption, or they may develop in normal skin. When sufficiently developed tubercular or nodular leprosy is essentially a bilateral, symmetrical disease. In some cases individual tubercles cannot be distinguished, but the whole skin of the face is greatly infiltrated, thickened and discolored, the surface remaining smooth, or, more often, cut by furrows sometimes a quarter of an inch deep in the natural lines of cleavage, or in the folds of the forehead, cheeks or chin. This furrowed type is especially marked on the cheeks and forehead and gives the leonine expression to the countenance more strikingly than the other varieties. In other cases the tubercles preserve their integrity, studding the face in their favorite areas of distribution with nodules varying in size from a pea to a marble. The color is usually a dusky reddish-brown, or may be waxy white in those cases in which the lesions are scattered and which are usually the most malignant. Each individual nodule is rounded at the base and

spherical in contour, much as if peas or marbles had been stuck in the skin.

The eyebrows and beard may fall in this type, but as the scalp is not usually affected its hair may be preserved in its integrity until very late in the disease or to its termination.

Periodically in the course of the disease there may occur an outbreak of tubercles, evanescent in character, highly inflammatory and very painful. These occur during the course of the lepra fever before mentioned, which may last from one to five or six weeks, or even longer. These tubercles are deep-seated and dull red in color, not showing the brown pigment of the chronic type. They fade away with the subsidence of the fever and sometimes one crop will disappear to be replaced by another before the temperature returns to normal. The inflammation in this type is sometimes so intense that vesicles and bullæ develop on the tops of the tubercles, and some may even undergo suppuration with the formation of abscesses. Their distribution over the body is far more general than that of the permanent tubercles, as they occur not only on the face and hands but also on the trunk and on both the flexor and extensor surfaces of the extremities. The type of fever referred to as lepra fever is not the fever usually described as one of the prodromal symptoms of leprosy, but is an irregular elevation of temperature ranging from 100 to 104 F., and associated either with marked changes in the macules or tubercles present before the occurrence of the fever, or with the formation of such tubercles as have just been described. These tubercles may be especially recognized by their tendency to uniformity in size and their usual lenticular shape as if a flat bean were embedded in the skin.

The lepra fever has two distinguishing symptoms, the rise in temperature and the development of tubercles different in many characteristics from the lesions found as the usual evidences of leprosy. In the tubercular and mixed cases it occurs at varying intervals of time and is of varying duration, while in the pure anesthetic and trophic cases, as there are no tubercles, the skin evidences are lacking. Though there may be periodic rises of temperature, they are often associated with the suppuration which is the result of nerve disturbances and which is more liable to affect the bones and joints than the skin; in consequence the cardinal point in the diagnosis of lepra fever is lacking.

The inflammatory evidences in the tubercles accompanied by a general rise of temperature occur in almost every case of tubercular or mixed leprosy, though the symptoms are sometimes of so slight a character as almost to escape observation. The temperature may vary from so slight a rise above the normal as to occasion merely a feeling of malaise, to a grave febrile condition. The range of temperature is from 99 to 105 or 106, and two cases have been observed in which the result was fatal. The attack is often ushered in with a chill, and the duration is very variable—from a few days to several weeks or even months. Some patients have been known to have as many as three or four attacks during one year. The chief features of the temperature chart are the remittent character of the fever, and the sudden great rises and fall of temperature. The chart of a well-marked case very closely resembles that of septicemia.

The occurrence of marked inflammatory symptoms in old tubercles, infiltrated patches, macules, or in areas of skin which apparently were previously healthy, is coincident with the rise of temperature and is characterized

by swelling, redness, pain and, rarely, suppuration. The occurrence is most frequent in old tubercles and least frequent in areas of skin which previously were not involved. The duration of the inflammatory nodules is short, but one crop is followed by another as long as the fever lasts. The location is most frequently on those parts of the body that are involved by the chronic characteristic nodules of leprosy, the face, neck, hands, and also the arms and legs. The distribution seems, like that of the chronic lesions, to prefer those parts of the body in which the temperature is lowest. The trunk is less frequently involved, and we have seen no cases involving the scalp. The number of lesions found at one time is very variable and they are disseminated with an irregular, bilateral symmetry. They vary from the size of a split pea to that of a hen's egg. The elevation above the surrounding skin is well marked and the nodules are of a globular contour, usually rounded in outline and distinctly limited in area. The color is uniformly red—a brighter and more brilliant hue than the dusky purplish red of the stationary tubercles, from which they can be differentiated not only by their inflammatory character but also by their rapid development, their evanescent character and an occasional tendency to suppurate and occur on parts of the body not usually affected by permanent bacillary deposits. Unless suppuration occurs the nodules are quite firm to touch and most resemble those found in erythema nodosum. It has been a matter of observation that often after attacks of lepra fever there has been improvement in the old tubercle and in the general condition, which seems to argue that during these attacks some bacillary product is formed which not only causes the elevation of temperature but also either directly affects the life or growth of the organisms, or indirectly, through the elevation of temperature, produces a condition unfavorable to the germ life.

In support of the latter view may be mentioned an observation made by Dr. F. B. Gurd, of the Department of Pathology of Tulane, in which the pus from an abscess caused by the suppuration of an inflamed tubercle was found to contain no organism except the bacillus of Hansen. These bacilli were found to be incapable of cultivation under the same conditions in which other Hansen bacilli had been found to flourish.

It is also interesting to note that during the administration of a series of hot baths, in which an effort was made to maintain an elevation of temperature of 104 for several hours, two tubercular cases developed lepra fever. If we may be permitted a little speculation, the great improvement derived from elevation of temperature, even in advanced cases of leprosy, may be explained on the hypothesis that the lepra bacillus does not thrive at high temperatures. The location of the chronic tubercles is very suggestive of this, as is also the improvement noted after erysipelas, lepra fever, and artificial elevation of temperature by means of hot baths. It seems possible that the products of the disintegration of dead bacilli provoke a general rise of temperature as well as the local heat of inflammation, and that the febrile condition thus produced reacts on bacilli in other locations, which, in turn, in their disintegration, liberate fever-producing toxins. It is conceivable that such a process should continue until all the less viable bacilli become destroyed, when the temperature returns to normal and old lesions show considerable improvement.

With the exception of the tubercle associated with the lepra fever the nodules of leprosy seem to have a marked preference for the exposed parts of the head. The scalp

is almost always free, while the ears are, on the contrary, almost always involved. They become enormously enlarged either by the presence of tubercles, in the lobes especially, or by a diffuse infiltration, both of which cause a marked discoloration. It is not unusual to find, even in terminal cases, tubercles present massed over the entire face and ulcerating, the limit of the most aggravated part of the eruption clearly marked by a line around the neck about where the shirt-band rests. On the trunk and arms and legs the macular eruption is far more common than the tubercular, though nodules may occasionally be found over a macular patch or even on a part of the skin presenting no other lesions. The tubercles never mass over the entire body as they do over the face. The most common condition on the hands is the thickening of the skin and pigmentation, with tubercles more sparsely scattered than on the face, the color being a dusky brown. The infiltration and swelling of the hands so affect the skin as often to cause a papery consistency like thin parchment.

The ulcers of leprosy are of two kinds, the perforating and the purely cutaneous. The latter occur most frequently on the face and on the legs. On the face they are usually superficial, but those around the mouth are liable to cause considerable destruction, and when the ulceration has healed the shrinking resulting from cicatrization will reduce the mouth to about one-third its normal size. The ulceration of the face occurs only in the terminal stage when the tubercles have become large and thickly aggregated, and it is found only in the tubercular and mixed types, the trophic form, or nerve leprosy showing in the face only by the infiltration of the whole mask of the face, with thinning of the epidermis, leaving the skin glossy and pigmented. The ears in this form are often flabby and pendulous; ectropion causes a stare, which is a peculiarity of this disease. The cause of the breaking down of the nodular masses seems to be due more to a disturbance of circulation in the skin than to the bacilli present, and this seems true also of the ulcers of the leg, where the circulatory balance is easily disturbed by gravity.

The perforating ulcer is associated only with the anesthetic form and is found only on the hands and feet, and more often on the ball of the foot than elsewhere. It is a surgical condition, being a sinus leading to necrotic bone. The horny layer of the skin is much hypertrophied when the ulcer is on the foot and the condition is painless.

A strong confirmatory symptom of leprosy is the anesthesia found in all types. In the tubercular type it is confined to the lesions, but in the anesthetic it spreads over the area of distribution of the nerve affected. The sense of pain and temperature are lost before the sense of touch, and in the anesthetic type the nerves most frequently involved first are the ulnars. The loss of sensibility begins usually in the tip of the little finger and spreads gradually to the adjacent fingers and up to the forearm. Other nerves become involved later on and the anesthesia may become general. In this instance there is always either marked thickening of the ulnar nerve or distinct nodes along the nerve. The left side is more often the first to be affected.

The mutilation in the anesthetic or nerve type is almost confined to the hands and feet, usually being limited to a loss of the fingers and toes, and is due to trophic changes caused by nerve destruction. The atrophy may be manifested by the "claw-hand," in which the flexor tendons and muscles shrink more than the extensor, drawing the fingers up and preventing exten-

sion, or it may affect the bones, causing either necrosis or a gradual degeneration and absorption.

When necrosis occurs, a perforating ulcer is established and persists until the fragment of dead bone, sometimes an entire phalanx, is discharged. The ulcer then heals, leaving the finger or toe shortened by the loss of bone. When necrosis with suppuration does not cause the loss of bone in mass, a slower process of absorption goes on, and the flexed fingers become shrunken masses of flesh with atrophied nails at their extremities.

The curious condition of an amputation at the joints by constricting circular atrophy, just as in the disease known as "ainhum," is often observed and fingers and toes are often lost in this painless way. A band of fibrous tissue forms around some part of the digit and gradually constricts the underlying tissues. The band is usually about one quarter to one-half inch in breadth, and as it grows tighter the tendons and bones under it atrophy until the finger is left hanging by a fibrous band, which can easily be cut off with a pair of scissors; or, if left to itself, the finger will fall away, the patient often being unconscious when the loss occurs.

The suppuration attending the necrosis of bone may extend to joints involving the articulations at the wrists and ankles and occasioning a condition like tuberculous or septic arthritis.

Considerable attention has been directed to leprosy in the United States and recent cases have enforced the belief that not enough emphasis has been placed on the training of government physicians with regard to this disease. The notoriety attaching to the Early case alone, which excited the qualified criticism of at least two distinguished foreign leprologists, may be cited in point.

The United States has specific immigration laws which require the deportation of lepers; yet in 1908 several patients with advanced leprosy were shown in New York at the International Dermatological Congress, and some of these cases were in recently imported foreigners.

Within the past three years Dr. Dyer has seen two lepers from Central and South America, who reached New Orleans by way of New York. These cases were well enough marked to have been recognized by any health officer who had even a meager idea of the disease.

It is highly important that the cardinal symptoms of leprosy should be learned by the officers of the public health so that importation of leprosy may stop. It does not require any more legislation, but more education of port physicians.

The salient points of diagnosis in leprosy consist in the recognition of the stamp of the disease, which is always suggested by the dusky hue, the swollen skin, the overhanging eyebrows and the raucous voice. The hands, too, have a thinned epidermis and an altered color which is different from that in any other disease. The presence of tubercles in the skin of the face, at the lips and about the nose, with others, in the pendulous parts of the ears—all these should make a case suspicious.

The differential diagnosis of leprosy, clinically, is at all times simple. There are only two conditions which at all resemble tubercular leprosy, iodism and disseminated tuberculosis cutis. The first-named condition is seldom seen in the areas common to leprosy and the nodules of iodism are highly inflammatory and ready to break down.

With tuberculosis of the skin, the lesions are numerous, small, and deep-seated, under the epidermis as a rule. They are dirty white in color and seldom assume

a reddened hue. Moreover, this condition on the face is unusual and when it does occur, the lesions are more apt to occur bilaterally and symmetrically, in numbers, on the cheeks and wings of the nose than elsewhere.

We would finally make the point that all physicians should report any cases of leprosy coming under their observation so that the actual occurrence of this disease in the United States may be studied and the statistics derived may be of some value in establishing an institution for the care of leprosy under government control and expense.

124 Baronne Street.

ABSTRACT OF DISCUSSION

DR. A. RAVOGGI, Cincinnati: It would be somewhat difficult to measure the value of fever as a diagnostic factor in these cases. The fever is usually present in the early stage of the disease, but we seldom see cases of leprosy in their development. We usually see them when they begin to suffer from neuralgic pains or during the eruptive stage. It is extremely difficult to establish the diagnosis of leprosy in the second stage, when the eruption which we call the leprides are developing, as they can easily be mistaken for various kinds of eruptions. The only characteristic symptom is when they show the toxic erythema—large, reddish patches on the arms or in other regions which usually are accompanied by severe neuralgic pains when the nerves have become involved. In the later stages, when the tubercles form, the disease is more readily recognized. I have seen cases where there was scarcely any eruption—merely spots of cloasma or vitiligo and neuralgic pains. Then the hands begin to be paralyzed and take on that peculiar appearance, hand-drop. In one case only a large leproma developed on the knee and another on the foot, causing ulcer which involved the joint and the bones. I firmly believe that with a little experience and attention it will not be difficult to establish the diagnosis of this disease, which should be stamped out. This is being done with brilliant results in Norway. In the United States we have about 278 cases, some in North and South Dakota from Iceland, some in Minnesota from Sweden and Norway, some in Louisiana from the Bahama Islands, some in San Francisco from the Orient, and other scattered cases here and there. It is important, I think, that the United States Government should take up this question. We had a case in one of the hospitals in Cincinnati, in which the diagnosis of leprosy was fairly positive. The patient was a negro soldier who had spent four years in Cuba, and when we asked the health officer of the city what to do with him, we were told to let him go. I think it is dangerous that these patients should be allowed to remain in localities where they will be in free communication with other people.

DR. MARCUS HAASE, Memphis, Tenn.: I would not have had the opportunity of seeing a case of leprosy had it not been for this lepra fever. I would like to ask Dr. Dyer what percentage of these patients have this fever after the disease is fully developed?

DR. S. T. DARLING, Ancon Hospital, Canal Zone: The subject of leprosy is a very important one in the United States at this time when soldiers who have served in the Philippines and where employees from the Canal Zone are returning to take up permanent residences in various parts of the country. In the Canal Zone we have had no case of leprosy among Americans, and but one in a European. Our quarantine officers have been alert and active in the detection of the cases passing through their hands. We find that the diagnosis of the nodular form of the disease is easy. In fact, several of our cases have been detected by district sanitary inspectors, who are laymen. The anesthetic type of the disease presents greater difficulties. In these cases it is important and necessary in the examination to strip the patient and look for the presence of the characteristic annular areas of anesthesia and discoloration of the skin on the back, breast, abdomen and buttocks. These cases frequently present circular ulcers on the feet between the second and third toes. We have at times removed parts of the enlarged ulnar nerve for diagnosis

and failed to detect bacilli. The x-ray as a diagnostic aid has been used by Dr. A. B. Herrick, Ancon Hospital, for, in association with trophic ulcers of the feet in the anesthetic type there is a definite atrophy of the phalanges near the ulcer, which is well shown in radiographs. I believe Scheube has called attention to the fever of leprosy, but I do not think it is of much importance in the diagnosis of cases of leprosy of the anesthetic type.

DR. WILLIAM LITTEKER, Nashville, Tenn.: I was greatly interested in Dr. Dyer's explanation of the fever in leprosy. I think he is correct when he states that it is due to some form of intoxication. This intoxication is in all probability due to the toxins, or disintegrated products of the lepra bacillus. It seems that the patient gets better several days after the fever. This would indicate that the liberated lepra toxins would cause an increase in the opsonic power of the blood, similar to that seen as a result of tuberculin administration. While I do not know whether or not it is feasible, I would suggest taking an emulsion of the lepra bacilli after their growth on a proper medium and injecting the bacilli as a means of treatment.

DR. I. DYER, New Orleans: I again wish to make the statement that my paper was not an academic presentation of the subject, but rather a discussion of its salient features, because of the evident ignorance of the disease in our own country. Drs. Duval and Gurd, the pathologists of Tulane College, intend to present to the Society for the Study of Tropical Medicine a culture of the lepra bacilli which they have successfully carried on since last December, and we have already considered the elaboration of a vaccine. We hope, before another year has gone by, to have something to report in that line. In my paper, I purposely omitted any discussion of the subject of the laboratory diagnosis of leprosy. The discussion of anomalous types of the disease is largely covered in the portion of my paper which I omitted in reading. With us, and in all countries where the disease is fairly virgin, the anesthetic type is much more difficult to recognize than the tubercular. Such cases have been mistaken for syringomyelia by neurologists.

With reference to lepra fever, we have considered only that fever which occurs after the disease is well defined, and not that observed in the prodromal stage. In most of the cases of skin leprosy, which we have termed the tubercular type, this fever is often observed after the disease is well developed. As these cases have improved—and fully 90 per cent. of our cases have undergone a high degree of amelioration—the fever has always been associated with the improvement. In Louisiana, leprosy has been recognized and demonstrated since 1778.

THE SIGNIFICANCE OF EDEMA OF THE SOFT PALATE

LEWIS S. SOMERS, M.D.
PHILADELPHIA

Not infrequently an apparently trivial symptom may be the expression of a serious affection, and if it is unheeded and the opportunity for active treatment allowed to pass it may lead to a fatal termination before its true significance has been appreciated. Such a symptom is edema of the soft palate, and especially the uvula. When observed its possible gravity must be seriously considered. Edema of the soft palate chiefly involves the uvula, but may affect the faucial pillars, especially the posterior, or even the lateral pharyngeal wall. The uvular swelling may be slight, appearing as a glistening drop at its tip, or may be so massive that the faucial isthmus is occluded and breathing becomes impeded. The most frequent and at the same time trivial type is found in those who use the voice excessively, such as professional speakers, or improperly, even for a short time, such as impromptu orators. This is illustrated by the following case:

CASE 1.—A. G., male, aged 32 years, had excellent general health, but granular pharyngitis caused him to clear his throat frequently. He had been speaking every evening for a month at political meetings with no discomfort, when, after a long speech in the open air, he felt as if a foreign body was in the throat and was obliged to swallow constantly. Examination showed a bead-like swelling on the tip of the uvula, above which the mucosa was inflamed.

Such a case is an acute traumatic uvulitis and is purely local. No serious significance can be attached to it except that edema of any portion of the upper air-passages, it matters not how slight, carries with it the possibility of extension to the larynx, with all the seriousness that it implies.

Associated with general affections, as rheumatism, grip, etc., or with local conditions, as peritonsillar abscess, acute uvulitis is not infrequent, and in some cases of grip the brunt of the inflammation may be borne by the soft palate, with more or less swelling of the uvula.

Again, edema may occur as the result of direct traumatism, such as is caused by operations in this region and the application of the cautery to the tonsil, or it may occur in association with ulcerative processes of the mouth and pharynx, while sometimes it is seen as part of acute pharyngitis. In some individuals there exists a marked vulnerability to attacks of acute inflammation of the uvula with edema, so that on the slightest provocation pain and edema develop, causing difficulty in deglutition and possibly dyspnea.

Severe inflammation of the adjacent tissues is frequently attended with edema, especially in peritonsillar abscess, when serious symptoms may result from the enormously swollen uvula, and also from the glottic edema which may be associated with it. In peritonsillar abscess of any duration, edema of the adjacent tissues is a part of the morbid process and, in severe cases with much pus, an active factor in its production is blocking of the intercellular spaces with leukocytes, the blood channels being dilated, so that the escape of fluid into the tissues becomes conspicuous. An exaggerated case of this type, in which the edema was limited to the uvula, is the following:

CASE 2.—A man of 43, an abstainer from alcohol, in perfect general health, would have a peritonsillar abscess at intervals of one or two years; and at the time the edema occurred, the tonsillitis had lasted three days, when I first saw him. The right tonsil was involved and the most striking object on examining the throat, was the enormous uvula, filling up the space between the tonsils and causing great difficulty in swallowing. It resembled a nasal polyp; when it was incised, considerable fluid escaped, giving great relief. The edema disappeared after the evacuation of the peritonsillar pus collection, which was accomplished at the same time.

In some cases edema is a prodromal symptom of acute articular rheumatism, occurring as a symptom between attacks or seen in conjunction with gout. True gout in this relation is uncommon in this country, but is more frequent abroad and may show as an acute faucitis with edema of the uvula, which disappears as a gouty inflammation suddenly develops elsewhere. In such cases, described by Lermoyez¹ as acute pharyngeal gout, the edema is prominent and, as a prodromal symptom of a grave disorder, demands the most particular care. There is a sudden onset of faucial inflammation and fever, and the patient complains greatly of sore throat, but the pain is in excess of the objective symptoms, as the inflammation is limited.

1. Lermoyez: *Ann. d. mal. de l'oreille*, May, 1902.

The most conspicuous symptom, however, is uvular edema. There is never exudation, as in some other forms of tonsillitis, and after lasting for two or three days the symptoms disappear, to be replaced by an attack of gout elsewhere. Such pharyngeal symptoms, but less severe, may precede an attack of rheumatism, lumbago, sciatica, etc., and it will often be found that edema of the uvula is present, although frequently not observed by the physician, as it disappears in a few hours on development of frank rheumatism.

It has seemed to me that these cases may be divided into two fairly well-defined classes; those in which the organisms concerned in the throat affection possess excessive power of producing toxins and which are clinically characterized by edema in the throat and disturbance of the general metabolism, while in the other class the toxin production is limited and the organisms are characterized by local exudation. The arthritic diathesis at times seems to play a prominent rôle and, when a predisposed individual is exposed to chilling or dampness, pharyngitis or faucitis with edema is apt to ensue promptly, to be followed by an outbreak of so-called rheumatism. In another group of cases the throat manifestations are more mild, but characterized by the edematous uvula. There is fulness, increased during deglutition, the muscles feel rigid and the mucous membrane is inflamed. The edema, however, is not of sufficient intensity to cause serious symptoms, but is significant as a local expression of a general impairment of metabolism. The following patient shows this condition:

CASE 3.—The patient, a man aged 25 years, runs an elevator and is continually in a draught. He had two attacks of sore throat the previous year in which the uvula only was involved; it was so swollen that he could not swallow food. Each attack was followed by rheumatism involving the knee, shoulder and ankle-joints. The present attack began with a sore throat which caused little annoyance for a week, when the uvula suddenly became swollen and prevented the patient from eating. Examination showed it to be purplish-red, edematous, with congested blood-vessels ramifying over the surface; and its tip, lying on the base of the tongue, produced a constant desire to swallow. Six hours later this entirely disappeared, the shoulder and knee-joint became inflamed and the patient suffered for several weeks with rheumatism, but had no further edema of the uvula.

In severe types of faucitis, as erysipelas or septic infections, edema of the uvula is nearly always an accompaniment and is most serious, as it signifies a grave type of infection with tissue destruction, while the imminent danger of glottic edema is always present. In erysipelas, either as an extension from the dermal surface or, more rarely, arising as a primary pharyngeal infection, the swelling is so great that even a small degree of edema has a most grave significance and its development seriously aggravates the dyspnea and general prostration. In chronic specific affections, as tuberculosis and syphilis, the development of uvular edema may occur late and is significant of destructive local lesions with grave general debility.

As an indication of serious organic changes in the kidneys, edema of the uvula should arouse suspicion, as it may be the only symptom of approaching uremia, although edema of the larynx is more frequently observed as a symptom in this respect. Edema of the uvula is rare in acute nephritis, but occurs in cases of scarlet fever, in which the edematous uvula represents both the virulence of the local infection and the sub-

sequent toxic nephritis. F. Berine² reports an instructive case in a man of 35. There was an indefinite acute febrile attack with albuminuria, and the soft palate became edematous. The pharyngeal condition rapidly disappeared under treatment directed to the renal affection. While not frequent in chronic nephritis, except as a terminal symptom, it may be the first evidence of a general hydremia, the result of venous stasis, or may be part of a so-called nephritis pharyngitis, in which the mucous membrane shows atrophic disturbances with hemorrhagic streaks over the soft palate and posterior pharyngeal wall. In these cases it will be found that the local affection is the expression of a toxemia and, with but few exceptions, the kidneys are the underlying cause or, what is practically the same, there is high arterial tension with arteriosclerosis, and these organic changes show themselves both in the cardiac and renal structures. It may also be a prominent symptom of uremia in chronic nephritis, and then presents the most grave aspects, as the following case shows:

CASE 4.—The patient, E. K., a man aged 38, a machinist, used alcohol to excess for many years. When first seen at my clinic at the Stetson Hospital, he complained of dyspnea and dysphagia; the uvula was swollen, almost filling the faucial space and the larynx could not be seen. No history was obtained, as the patient was intoxicated, but there was no evidence of laryngeal involvement and the uvula was freely incised with considerable relief. As he lived close at hand, he was sent home and told to return if he had any difficulty with breathing, or if the improvement did not continue. Two hours later he was admitted to the hospital with great dyspnea and his wife stated that he had been constantly drunk for the past three weeks. He was weak, pale and sweating; could only whisper and could not lie down. The urine showed albumin, granular and hyaline casts and the condition was readily recognized as uremia. Under active treatment the uvula edema disappeared, but the general condition became worse; the patient developed wild delirium and died on the third day. In this instance the fatal termination was from the toxemia and not from the edema, as the latter entirely disappeared before death.

While edema here does not produce a lethal issue, it always presents a serious aspect on account of the danger of laryngeal involvement, and this is especially true in that group of vasomotor cases which are angioneurotic in character. Such cases represent a local manifestation of a general condition, intestinal toxemia at times being the underlying factor. An instance of this kind is reported by Gardier,³ in which edema occurred two hours after a meal, relief being obtained by active purgation. The swelling of the uvula in angioneurotic edema may be enormous, with great difficulty in swallowing and symptoms of suffocation, but active treatment gives prompt relief from the terrifying symptoms. For a time it may be the only symptom and cause great concern, or it may appear in conjunction with wheals on the dermal surface, while in several cases which I observed, it disappeared on the outbreak of localized swelling of the skin. A similar case was reported by Ballinger,⁴ in which edema of the pharynx suddenly appeared in a nervous young woman suffering from hay-fever, then rapidly disappeared, to be replaced by an attack of urticaria. Likewise, Hinsdale⁵ reported a case in which the body was covered with urticaria, the uvula was edematous and allowed the entrance

of air only, with difficulty, but there was no swelling of the laryngeal tissues. Such conditions may occur in digestive disorders or following operation with considerable traumatism, and may also be associated with intranasal changes such as acute inflammation with pus formation. Acute nasopharyngeal inflammation may be its cause when its gravity is dependent on the degree of infection.

So far as drugs are concerned in the production of edema, it can be appreciated that corrosive poisons, when swallowed, may produce it, but other than this the presence of edema would hardly suggest such a factor, although Price-Brown⁶ saw a case in which, following the application of 10 per cent. cocaine to the nasal chambers, edema of the uvula rapidly ensued several times, spontaneously disappearing a few hours later. In a case recorded by Ward⁷ edema followed a large dose of scopolamin. Many miscellaneous causes may play a part in its development, but in the majority of cases traumatism, either direct or indirect, is a most important factor. The former is illustrated by the edema caused by swallowing corrosive poisons, or by acids and burns, but in such cases it presents little significance, as the effect of the poison is of greater import elsewhere and its only significance is in indicating other grave conditions. In this connection a case is reported by Foster,⁸ in which a man of 54 years drank scalding coffee; there was severe pain localized to the soft palate and the voice was lost. Examination revealed the arches and tonsils concealed by the greatly distended uvula; there was no edema of the larynx, and cure was obtained in a short time.

Edema of the tip of the uvula, resembling a drop of fluid, is frequently found and causes little concern. Nocturnal mouth-breathing is a not infrequent factor, while the hawking of many individuals with postnasal catarrh, in their efforts to remove inspissated secretion, is also a traumatic cause. Reardon⁹ reports a case of edema caused by attempts to dislodge crusts from nasal suppuration. Vomiting may act in the same manner; Shurly¹⁰ reports such a case, in which vomiting produced great intumescence of the uvula.

The question arises as to why the uvula should present edema in such a number of conditions, some only local and of little import, while others, such as those associated with renal lesions, present the most grave significance. Two factors are especially concerned in the mechanism, one already mentioned, that of traumatism, and the second, i.e. structure of the uvula. At this portion of the palate the mucous membrane is thicker and less compact than that of other parts, especially so at its tip, so that it tends to favor the production of serous exudation here rather than at other points. In addition, edema occurs where the submucosa is well developed, and such is the case here to an unusual degree, as the bulk of the uvula is composed of areolar tissue with a loose-meshed arrangement of the cells, so that even slight congestion may be accompanied with a rapid development of edema. The size of the uvula plays some part in this respect, as, when large and broad, it is more apt to show edema than when thin or short, the latter form usually showing a drop on the tip,

while the broad uvula presents a massive type with serous exudation in the deeper layers.

The symptoms vary from slight tickling or scratching to a feeling as if a foreign body was present and producing suffocation. Where edema is slight the subjective symptoms may be absent, while there may be considerable dropsy unnoticed by the patient on account of the severity of the local conditions producing it, such as a peritonsillar abscess. In many cases the condition is most harassing because of the constant attempts to clear the throat and on account of the irritation of the tongue and epiglottis by the enlarged uvula; nausea and vomiting may be produced, while a hacking cough is frequent. The voice becomes hoarse and this hoarseness is enhanced in severe cases by excessive mucous secretion. All the symptoms are aggravated by the recumbent posture, and if the edema is extensive it is impossible for the patient to lie down without attacks of suffocation.

The appearance depends on the amount of serous exudation and, while in the majority of cases its original form remains preserved, yet, when the edema is excessive, it loses its outline and may become corrugated, or appear as a semitransparent ovoid mass. Finally the color may be significant of the proximate etiologic factor, for when the edema is the result of passive congestion the uvula is gray or blue-gray, like a translucent grape, while the inflammatory type, indicative of local changes, is characterized by a red hue increasing in intensity as the intumescence becomes augmented, until, in excessive infiltration, the vascular stasis is productive of a purple color. The color alone, however, is of little value, as the edema can never be mistaken, but the important factor is its grave significance in some cases and the necessity in all cases of ascertaining the underlying factors concerned in its production.

3554 North Broad Street.

ULTIMATE RESULTS IN THE TREATMENT OF PULMONARY TUBERCULOSIS WITH MERCURY SUCCINIMID

H. J. HARTZ, M.D.
PHILADELPHIA

The treatment of pulmonary tuberculosis with mercury has been highly extolled in the past few years by Dr. Barton Lisle Wright, of the United States Navy. The results obtained seemed so remarkably successful that a series of cases were selected and were placed under the mercury treatment.

A variety of cases were selected in an endeavor to ascertain in which type the treatment gave the best results. The classification of the different stages of the disease is the same as the one adopted by the National Association for the Study and Prevention of Tuberculosis.

The treatment consisted in the administration of a sterile solution of mercury succinimid in 1/5 gr. doses every second day, as advocated by the originator of this method of treatment. The hypodermatic injections were given into different portions of the body, including the buttocks, loose tissues of back and abdomen, and into the deltoid muscle. An attempt was made to administer the mercury intravenously and several injections were given into the median basilic vein. The intravenous route, however, was soon abandoned, as it proved unsatisfactory since it required some preparation of the

10. Shurly: Diseases of Nose and Throat, D. Appleton & Co., New York, 1900.

part and carried with it the element of danger of a possible thrombus formation.

The injections into the deltoid muscle seemed to have been preferred by most of the patients for the following reasons:

1. The part was easily exposed and easily sterilized.
2. The patient did not suffer any discomfort from sitting, as was often the case when the injections were given into the buttocks.
3. The patient could sleep and turn from side to side without suffering from the painful swelling which would often result at the site of the injection.

Twenty cases in all were selected, there being ten men and ten women in the series. The enumeration of the patients is in the order of the number of the injections that each had received. The hygienic and dietetic treatment of the patient was not changed during the period in which the mercury was administered. The patients were given the regulation amount of milk and eggs and were encouraged to spend more of their time in the open air. The examination of the sputum was performed in all cases, the urine and feces of many of the patients were also examined for tubercle bacilli, and blood-cultures were made in over one-half of the cases. Only those patients were selected who showed undoubted signs and symptoms of the disease, who had been for a long time under observation and whose cases were in the majority of instances of a chronic, non-active and generally favorable type.

The range of ages of the men was 20 to 55 years; average 41 years; the range of ages of the women was 18 to 62 years; average, 38.4 years.

The types of cases included in the series were as follows:

Incipient—arrested or stationary.....	2
Incipient—slowly progressive	2
Moderately advanced—had improved under hospital treatment	2
Moderately advanced—apparently cured.....	2
Moderately advanced—stationary or arrested.....	6
Moderately advanced—showing slow deterioration of general condition	1
Miliary—bed patients, progressive.....	2
Advanced—bed patients, progressive.....	2
Laryngeal—moderate advancement in lungs.....	1

According to activity of disease the cases may be classified as follows:

Arrested, stationary and apparently cured, 10 cases. 50 per cent.
Improved under general treatment, 3 cases..... 15 per cent.
Active, with local or constitutional symptoms, 7 cases. 35 per cent.

In view of the very striking ultimate results it has not seemed necessary to attempt to describe the course of the patients' condition during the treatment. In a general way it may be said that some showed temporary improvement in their condition, but it could not be very definitely attributed to the mercury, as it differed in no way from that in the non-treated cases. All the patients were receiving the general hygienic and dietetic treatment at the same time. Eventually, however, all the patients began to deteriorate, almost in direct proportion to the number of injections that each had received. From a careful study of the cases during the course of treatment it was observed that mercury had no specific effect on the course of the disease, and showed no tendency toward checking the local involvement in the lungs. Several patients (Cases 1, 3, 5 and 6) showed temporary improvement in their general condition, but it was probably due to the therapeutic action of the mercury in the associated anemia. These pa-

tients, however, shortly afterwards began to fail in health, and the deterioration was more rapid than in those who had not received the mercury. The quiescent lesions in the lungs became active, infiltration into the healthier tissues of the lungs occurred, cough and profuse expectoration and marked constitutional symptoms became progressively worse, thereby causing grave nutritional disorders, until the patient finally succumbed to the disease. A predisposition to hemorrhage manifested itself in several cases (Nos. 1, 3 and 7), particularly in the fibroid type, and it was the immediate cause of death in two (Cases 1 and 7). Salivation and pains in the bones developed in three of the cases (Nos. 3, 4 and 15), and treatment had to be abandoned on this account. Two of the patients, who received thirty injections each, had a positive history of a syphilitic infection during their earlier life (Cases 2 and 3), and the mercurial injections in these two patients were borne with greater impunity; one of the patients (Case 3) was alive fourteen months after the last injection with slight changes in his general condition, but occasionally was confined to bed on account of hemoptysis, or for a transient pleuritic affection. The only other patient (Case 4) who is alive, of the group that received six or more injections, is now suffering from a pyopneumothorax and has had several aspirations performed. For the past two months this patient has lost rapidly in weight, is very weak, and death with her is only a matter of weeks.

ENUMERATION OF PATIENTS ACCORDING TO NUMBER OF INJECTIONS AND ULTIMATE RESULT ONE YEAR AFTER TREATMENT

Case.	Injections.	Result.	Case.	Injections.	Result.
1.—D. F.	30	Dead	11.—E. D.	10	Dead
2.—N. B.	30	Dead	12.—M. F.	8	Dead
3.—J. M.	30	Living	13.—T. M.	8	Dead
4.—M. M.	22	Living	14.—F. B.	6	Dead
5.—M. N.	15	Dead	15.—W. H.	4	Dead
6.—M. D.	15	Dead	16.—J. J. K.	4	Living
7.—J. O'D.	12	Dead	17.—R. H.	4	Living
8.—R. S.	10	Dead	18.—M. R.	3	Living
9.—J. H.	10	Dead	19.—M. C.	2	Living
10.—J. K.	10	Dead	20.—A. S.	2	Living

One year after the treatment had been discontinued the following results were noted in the patients who had received the mercury injections. Of the fourteen patients who received six or more injections twelve died from two weeks to six months after the last injection. Of the remaining two (Cases 3 and 4) of the fourteen patients who are alive, one (Case 3) has had repeated hemorrhages and is occasionally confined to bed, the other (Case 4) has had several aspirations because of pyopneumothorax, and is rapidly failing in health. This enormous percentage of deaths, namely, 85.7 per cent., among those patients who received six or more injections, can be attributed only to the use of mercury, simply from the fact that the expectation of life in many of the cases chosen was very favorable indeed. In fact, on account of the age of the patients and the chronic arrested type of the disease, they were the kind of patients who live long and have a favorable prognosis. Further, it may be noted that of the six patients who received four injections or less, five are alive and only one (Case 15) died, giving a mortality of only 16.6 per cent. as compared with the mortality of 85.7 per cent. of those who received a greater number of injections. Of the patients who had received the fewest injections, 83.4 per cent. are alive, while only 14.3 per cent. are alive of those who had received a greater number of injections.

To sum up, of the fourteen patients who received six or more injections, twelve, or 85.7 per cent., died, and

two, or 14.3 per cent., lived. Of those who received four injections or less, one, or 16.6 per cent., died, and five, or 83.4 per cent., lived.

CONCLUSION

From the above results the only deduction that can be drawn is that mercury, as recommended, has utterly failed as a specific agent in the treatment of pulmonary tuberculosis, and is positively injurious and detrimental to one afflicted with tuberculosis.

I am greatly indebted to Dr. A. P. Francine and Dr. H. R. M. Landis for the many suggestions offered in the preparation of this paper.

REPORT OF CASES

CASE 1.—Thirty injections.

D. F., a white man, aged 20, single, bookbinder, came under observation Sept. 20, 1908; died Aug. 25, 1909.

Type: Incipient, active.

The patient was well developed, well nourished and of medium stature. Infiltrations in both upper lobes were slowly progressive.

Result: The patient improved for five weeks, then began to fail in health rapidly, had several hemorrhages and died six months after last injection.

Reason for discontinuing treatment: poor health, hemoptysis.

CASE 2.—Thirty injections.

N. B., a white woman, aged 34, married, housewife, came under observation Oct. 30, 1908; died March 3, 1909.

Type: Moderate advancement, stationary.

The patient was a frail woman of medium stature and showed several resulting lesions of a previous syphilitic infection.

Result: She did not improve, but failed in health and died three months after last injection.

Reason for discontinuing treatment: Failing health.

CASE 3.—Thirty injections.

J. M., a white man, aged 45, married, a laborer, came under observation July 3, 1908, and was alive April 1, 1910.

Type: Moderate advancement, stationary.

The patient was large, well developed and fairly well nourished, with a history of a previous syphilitic infection.

Result: He improved for several weeks; a few months later hemorrhages developed which confined him to bed. One year after injections the patient is alive, but much weaker.

Reason for discontinuing treatment: Patient began to show signs of salivation.

CASE 4.—Twenty-two injections.

M. M., a white woman, aged 34, married, housewife, came under observation Dec. 17, 1906, and was alive April 1, 1910.

Type: Moderate advancement, stationary or arrested.

The patient was well developed, well nourished and of short stature, with no constitutional symptoms.

Result: There was no apparent improvement. The patient is alive one year after last injection in a very much weakened condition, and is suffering from pyopneumothorax.

Reason for discontinuing treatment: Salivation.

CASE 5.—Fifteen injections.

M. N., a white woman, aged 34, widow, housewife, came under observation Nov. 12, 1903; died Jan. 18, 1909.

Type: Advanced, progressive.

The patient was of medium stature, of fair development and nutrition.

Result: There was slight improvement for two weeks, then she failed rapidly in health and died one week after last injection.

Reason for discontinuing treatment: Patient very weak.

CASE 6.—Fifteen injections.

M. D., a white woman, aged 47, widow, housewife, came under observation Aug. 26, 1908; died March 29, 1909.

Type: Moderately advanced, progressive.

The patient was of small stature, of fair development and poor nutrition.

Result: She showed slight improvement for two weeks, but died two months after last injection.

Reason for discontinuing treatment: Patient refused injections.

CASE 7.—Twelve injections.

J. O'D., a white man, aged 48, single, a laborer, came under observation April 9, 1909; died March 14, 1909.

Type: Moderately advanced, progressive.

The patient was large, of good development, good nutrition and with no constitutional symptoms.

Result: There was no change in condition during treatment. Four weeks after last injection the patient had several severe hemorrhages and died two weeks later.

Reason for discontinuing treatment: Patient refused injections.

CASE 8.—Ten injections.

R. S., a white woman, aged 32, married, housewife, came under observation Dec. 16, 1908; died Jan. 8, 1909.

Type: Miliary progressive.

The patient was of large stature, good development, good nutrition.

Result: The first two injections were followed by a drop in temperature from 104 to 98 F. The patient failed rapidly in health, and died two days after last injection.

Reason for discontinuing treatment: Death.

CASE 9.—Ten injections.

J. H., a white man, aged 40, single, a laborer, came under observation Oct. 14, 1908; died May 8, 1909.

Type: Moderately advanced, improved on hospital regime.

The patient was of good development and good nutrition.

Result: There was no improvement. The patient progressively failed in health and died four months after last injection.

Reason for discontinuing treatment: Patient refused injections; felt worse.

CASE 10.—Ten injections.

J. K., a white man, aged 31, single, a laborer, came under observation Oct. 23, 1908; died July 31, 1909.

Type: Incipient, slowly progressive.

The patient was of good development, good nutrition and apparently in robust health.

Result: There was no change; four weeks later the patient began to show signs of slow deterioration and died six months after receiving last injection.

Reason for discontinuing treatment: Hard painful swelling.

CASE 11.—Ten injections.

E. D., a white girl, aged 18, single, a bookbinder, came under observation Oct. 19, 1908; died Jan. 5, 1909.

Type: Miliary, progressive.

The patient was of small stature, frail development and fair nutrition.

Result: There was no improvement. The patient failed rapidly in health, and died three weeks after last injection.

Reason for discontinuing treatment: Rapidly failing health.

CASE 12.—Eight injections.

M. F., a white woman, aged 24, single, a factory girl, came under observation June 5, 1908; died Jan. 6, 1909.

Type: Moderately advanced, improved under hospital regime.

Result: The patient became worse under mercury injections, and died two weeks after last injection.

Reason for discontinuing treatment: She asserted that she felt worse; refused injections.

CASE 13.—Eight injections.

T. M., a white man, aged 38, single, a fireman, came under observation June 20, 1908; died Dec. 27, 1903.

Type: Advanced, progressive.

The patient was of medium stature, fair development, poor nutrition and asthenic.

Result: The patient became worse and died one week after last injection.

Reason for discontinuing treatment: Death.

CASE 14.—Six injections.

F. B., a white man, aged 55, widower, laborer, came under observation Oct. 26, 1908; died Feb. 15, 1909.

Type: Moderate advancement, stationary.

The patient was of small stature, poor development and fair nutrition.

Result: There was no improvement. The patient died six weeks after last injection.

Reason for discontinuing treatment: Patient refused injections.

CASE 15.—Four injections.

W. H., a white man, aged 43, widower, plumber, came under observation Dec. 10, 1908; died May 7, 1909.

Type: Laryngeal, moderate advancement in lungs.

The patient was a well-developed adult and of fair nutrition.

Result: He became salivated after four injections, complained of pain in bones, and died four months later.

Reason for discontinuing treatment: Salivation.

CASE 16.—Four injections.

R. H., a white woman, aged 46, widow, housewife, came under observation Sept. 15, 1908, and was alive April 1, 1910.

Type: Incipient, arrested.

The patient was of good development and good nutrition.

Result: There was no change, and she is practically in same condition one year later.

Reason for discontinuing treatment: Painful swelling.

CASE 17.—Four injections.

J. J. K., a white man, aged 49, a single laborer, came under observation Dec. 7, 1907 and was alive Dec. 10, 1909.

Type: Moderate advancement, apparently cured.

The patient was of large stature, of good development and good nutrition.

Result: There was no change in condition; one year later the condition is same as when treatment was discontinued.

Reason for discontinuing treatment: Patient refused injections.

CASE 18.—Three injections.

M. R., a white woman aged 62, single, engaged in housework, came under observation April 1, 1907, and was alive April 1, 1910.

Type: Moderate advancement, apparent cure.

The patient was of frail development and fair nutrition.

Result: There was no change and the patient is alive one year later in same condition.

Reason for discontinuing treatment: Patient refused injections.

CASE 19.—Two injections.

M. C., a white woman, aged 53, single, engaged in housework, came under observation Feb. 16, 1907, and was alive April 1, 1910.

Type: Moderately advanced, stationary.

The patient was a well-developed adult woman of good stature and fair nutrition.

Result: There was no change, and the patient is alive in practically same condition as a year ago.

Reason for discontinuing treatment: Patient refused injections.

CASE 20.—Two injections.

A. S., a white man, aged 39, a single laborer, came under observation Oct. 11, 1908, and was alive April 1, 1910.

Type: Incipient, arrested.

The patient was of good development and fair nutrition.

Result: There was no change in condition, and the patient is alive one year later in same state of health.

Reason for discontinuing treatment: Patient refused injections.

1002 Jackson street.

Pannus in Trachoma.—The distinguishing features of pannus are innumerable small blood vessels tortuous in their course, running down through the cornea. It may involve only the upper part or all of the cornea. If much of the cornea is involved, or if the disease is not early arrested, there will be changes in the corneal epithelium, resulting in haziness of the tissue, which is rarely entirely absorbed after the disease has been arrested. The younger the subject, the better will be the chances for complete absorption of the exudate.—C. B. Wylie, in *Journal of Ophthalmology and Oto-Laryngology*.

PLASTIC SURGERY OF THE PELVIC STRUCTURES*

HENRY O. MARCY, M.D.
BOSTON

As the members of this Section know, this is not the first time that I have addressed it on the subject chosen. I seek this opportunity because, I confess in advance, I am greatly disappointed in the results obtained by surgeons in various parts of the country. Patients come to me from widely scattered localities, having been operated on by surgeons of repute and of ability beyond question. Of course, it should be borne in mind that the cases thus seen are exceptional. If the experiences teach anything, the criticism applies to the method, rather than the operator.

REPORTS OF CASES

In illustration of this I shall cite three recent cases in young, healthy women.

CASE 1.—Mrs. B., aged 29, underwent instrumental delivery of a large child. An extensive laceration of the perineum, not involving the rectum, resulted. Six weeks after the delivery she was operated on by two of the leading surgeons of her city. On her admission to my hospital there was a marked cystocele, the cervix protruding through the vulva, with a pronounced rectocele. The posterior wall of the vagina had been cut away, leaving only a thin band of cicatricial tissue covering the rectum. The uterus was enlarged. There was a deep, double laceration of the cervix, with eversion.

A large, elliptical portion of the thickened anterior vaginal wall was excised and the anterior pelvic floor coapted by a line of deep, double buried tendon continuous sutures. The anterior vaginal wound was also closed by a single line of buried tendon sutures. The everted, lacerated cervical wounds were resected and closed with continuous tendon sutures. The perineal dissection was of course very difficult, but lateral flaps were secured by a deep dissection on either side, exposing the transversi, which were coapted and held in place by a double continuous buried suture. The posterior vaginal flaps were coapted by a single line of running buried sutures. An iodoform wool tampon in the vagina was the only dressing. The convalescence was easy and uneventful, and the restoration to the normal condition complete.

At the time of discharge from the hospital it would have been difficult to determine that the patient had ever been pregnant.

CASE 2.—The patient was a woman, aged 22. Conditions were so nearly like those in Case 1 that they do not require recapitulation.

CASE 3.—The patient was operated on a little more than a year ago by a leading surgeon in one of our Boston hospitals, and as in previous cases there was complete prolapse of the cervical portion of the uterus, with a marked cystocele and rectocele. Although in good general health the patient had been a great sufferer and a complete invalid for the entire year. Here also the posterior wall of the vagina had been dissected away, leaving very little covering to the rectum, but the pronounced feature was a constant purulent discharge from the vulva on both sides. This had been attributed to suppuration of the Bartholin glands. Much to my surprise the dissection revealed a long stay suture of silkworm gut, leaving a suppurating sinus throughout the entire tract where it had been buried.

These cases coming to me within a few weeks have impelled me to call the attention of the profession again to what I consider still a very common fault in technic. I must conclude that the basic principles of the operation are still in a measure misunderstood. A simple

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

definition of the term "plastic repair" of any of the pelvic structures would be to restore them to their normal anatomic relationships. The time at my disposal permits only the briefest reference to the anatomy and function of these most important structures.

The transversi muscles, interdigitating and blending with the great levator group, with the associated fascia, are the recognized supports of the pelvic floor. Their central juxtaposition forms the much-discussed perineal body.

REPAIR OF PELVIC FLOOR

The reunion and restoration of these sundered structures is the object sought by the surgeon. To reunite them they must be anatomically exposed. They must be retained in juxtaposition in aseptic condition and reunion or restoration necessarily follows. As I have long insisted, the dissection should be made by a free separation of about the posterior third of the vagina, quite to the crest of the rectocele, and sufficiently wide laterally to expose freely the torn retracted structures. This means a wound that, to one first seeing it, would seem unnecessarily large, but unless the dissection is wide and complete it is very difficult, often impossible, to obtain free access to the important structures thus widely and for a long time separated.

So far as possible, I deprecate the invention of new instruments unless they may be devised to accomplish an important purpose.

In the separation of the vaginal muscle from the rectum the cicatricial structures are often difficult of dissection. The cutting edge of the knife I use is at an angle of 45 degrees with the line of the handle. When the parts are held tense with the fingers in the rectum, the use of this knife facilitates dissection, especially of the retracted cicatricial attachment of the transversi muscles. I consider the needle important and have found no reason to change it in any material respect, since it was presented to the profession by me twenty-five years ago. It is strong, of convenient length, set in a handle with a marked curve and a modified Hagedorn point. The eye is of some importance, since the slot on either side catches and holds the suture, preventing it from slipping.

Two fingers of the left hand retained in the rectum during the operation aid materially in suturing. After a little experience it is easy to coapt and hold in retention the sundered structures with three or four strong double tendon continuous sutures. Light running sutures, best applied with the Hagedorn full curved needle easily coapt the less important structures, covering in the deep layer of sutures, while they themselves remain buried. If, for any reason it may seem desirable, it is perfectly easy to reform a hymen. The external wound is sealed with iodoform collodion, which, although it may loosen in two or three days, I consider a valuable protection from vaginal infection.

When the perineal rupture is complete, involving the sphincter and the bowel, the operation is almost as simple and easy. The vagina and rectal structures are carefully dissected. The rectum and sphincter are coapted, with a light line of double tendon sutures, the only care requisite being that they should be placed in aseptic structures. This slightly inverts the mucous membrane of the intestine. It is important to rejoin the sphincter fibers, as pointed out by Emmet many years ago. I sometimes use an independent suture of the sphincter muscle in order to secure a more firm coaptation. The posterior wall of the vagina is closed in a

similar way, reducing the factors of the problem to those of an uncomplicated perineal laceration. The structures are sometimes so attenuated and the rectum so contracted that a successful operation requires patience, a careful dissection and a delicate technic but I do not now recall a single case in which I have not had a complete restoration anatomically, with complete restoration of function. In the rectum I use a large drainage-tube, with a cravat attachment of iodoform gauze, to be left for some days.

VESICOVAGINAL FISTULA

Almost every surgeon, even of to-day, is familiar with the monumental labors of my late great master, Marion Sims. The corner stone of his reputation was based on his cure of vesicovaginal fistula. As we review his operation from the standpoint of modern surgery and experience, we understand that his success was based on two factors. The first was his extraordinary skill in the careful dissection of the wound. I know of no operator to-day who excels, or perhaps, even equals the facile skill and dexterity attained by Sims. The second factor to which he attributed his crowning success was the use of silver wire sutures. These were applied with a skill which I have never seen equaled. Of course we now recognize that it was an aseptic suture, most difficult to apply and almost equally difficult to remove.

As I look back over the experience of those early years, I almost shudder over the worry and anxiety which I had in the imitation of the methods of this great man. I expected only to follow him afar off and never hoped to duplicate his great skill. As I now recall his experience, his first cure of vesicovaginal fistula was effected only after thirteen failures. Even to the end, his successes were the exception. The method which for a good many years I have employed first occurred to me after a considerable series of easy cures in cases in which I had closed wounds in the bladder from a variety of causes, from within the abdominal cavity. These were invariably simple in technic and perfect in result. A double continuous suture easily closed the wound with perfect coaptation, care being taken, of course, not to penetrate the mucous membrane of the bladder. Following this a retained catheter easily kept the bladder wall in a state of rest.

Profiting by this experience I made a wide dissection of the bladder from the vaginal wall and closed the bladder wound by a fine double tendon suture, which of course became buried. I then closed the vaginal wound as described in the operation for cystocele. The object of this extensive dissection was to obtain complete rest of the bladder wound during the process of repair, which is impossible when the vaginal attachment has been permitted to remain and the suture is taken through both the bladder and vaginal muscle.

Fortunately vesicovaginal fistula is far less common than formerly, and in the cases in which there has been a large destruction of the structures, the surgeon's skill and resources will be taxed to the utmost, but in every case of vesicovaginal fistula operated on as described I have had complete and seemingly easy cure.

HERNIA OF THE BLADDER

Hernia of the bladder, unfortunately, is often unrecognized and classed, in a general way, with cystocele. It is caused by the rupture of a portion of the strong fascia which goes to make up the pelvic floor. It may not be always easy to differentiate it from cystocele,

and differs from it chiefly in that in the latter the whole anterior pelvic fascia is relaxed instead of presenting a more severe lesion of it.

Its cure is equally easy and satisfactory. As in cystocele, it is generally wise to remove a certain amount of the anterior vaginal wall. Then it becomes necessary to make the lateral dissection sufficiently free to expose the strong pelvic fascia and intra-fold it by a carefully applied, medium-sized double tendon suture. Indeed, the operation differs so little, except in the recognition of its anatomic cause, that the surgical procedures are not unlike those for the cure of cystocele.

HEMORRHOIDS

Viewed from the standpoint of discomfort and suffering, the marked changes often seen in the hemorrhoidal structures hardly belong to the province of so-called minor surgery.

I consider the most important contributions to the technic of hemorrhoidal operations are those of Mr. Whitehead, now recognized and described in all textbooks. My modification of the operation consists in a free dissection, exposing the outer rim of the sphincter muscle and suturing the hemorrhoidal plexus of vessels just within its borders. This line of sutures is covered and buried by a careful rejoining with the finest of sutures.

Suturing at the base, before division, occludes the vessels and prevents hemorrhage. The delicate anal structures, carefully coapted and retained in an aseptic condition, unite primarily without suppuration, and when the sphincter muscle has been paralyzed by careful dilatation, these tissues are easily kept at rest with very little suffering. Here, too, I usually seal with iodoform collodion since the protection of the structures by it for even a day or two is important. Of course the rectum has been carefully cleansed and the large tube with the cravat of iodoform gauze applied. The three factors necessary for success are the following: first, the making of a free, skilful anatomic dissection; second, a careful reuniting of the weakened injured structures by the use of buried absorbable sutures, preferably kangaroo tendon, and, third, the making and maintaining of an aseptic wound.

I recognize more fully than my readers the almost dictatorial brevity of the description of this treatment of the above group of pelvic lesions. Any one of them might properly demand a detailed description covering the space given to the entire group. Some might consider that I have given undue importance to the personal factor of individuality in the description, but I am sure that any good surgeon, after a little practice, can do these operations equally well, or better.

I have long since ceased to tabulate in a numerical way these operations, since little is gained by enumerating the multiplied experience of years.

A distinguished English surgeon sometime since was present at an operation and made pertinent inquiry as to the percentage of failures. I referred him to the matron of my hospital, who replied with something of surprise: "Not one, Doctor, since I have been here." "But how long have you been with Dr. Marcy?" She replied: "More than twenty years." This statement may not be strictly true, but it is essentially so, and the credit belongs, at least in equal share, to the faithful, devoted services of my enthusiastic nurses.

180 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. D. T. GILMAN, Columbus, O.: Dr. Marcy is probably the pioneer in the use of this absorbable suture and he is entitled to great credit for it. He gets results undoubtedly, but I cannot get the same results from an absorbable suture that he does. Dr. Marcy's method of introducing a couple of fingers into the rectum does not appeal to me. He has doubtless acquired an automatic asepsis from long practice that I would not have, and others would not have. I formerly used a knife for denudation, but I have practically abandoned it and have gone back to the scissors. If I have a good pair of scissors I do not need to have the fingers in the rectum; I simply put the tissues on the stretch.

DR. W. H. GILBERT, Evansville, Ind.: Dr. Marcy's technic, as we all know, is a technic unsurpassed. His results have the same uniform excellence. We all know that in the after treatment of perineorrhaphy it is extremely difficult to keep the region aseptic. I think the plan of sealing the parts with collodion is a most excellent one. Personally, I have ceased to use douches after perineorrhaphy. The technic I follow is absolutely dry. I use dry sponges, seal the parts with collodion and exercise the most rigid care in the after technic. Three times a day the perineum is thoroughly cleansed by bichlorid solution, and a bichlorid pack of dry gauze adjusted. I don't believe it is possible in the region of the perineum to secure absolute asepsis no matter how careful a technic is followed and no matter how carefully you wall off the perineum with towels, or how carefully the buried sutures are inserted. I have abandoned the routine use of buried catgut or kangaroo sutures in all parts of the perineum. I get the best results from non-absorbable sutures in the skin covering of the perineum and absorbable sutures in the muscles, fascia and vagina.

Eight weeks ago in a case of complete laceration there was operation immediately after delivery with non-union. Two weeks afterward a second operation was done by the same surgeon, which was a failure. The last operation was done by myself ten days ago. The line of laceration of the rectum was closed with catgut sutures with the knot on the inside of the perineum without any of the catgut being in the rectum. It is impossible to put absorbable sutures in the rectum and not have infection. Two deep sutures of silk-worm gut were inserted with the needle devised by Dr. Marcy. The one point necessary in the securing of good results is that alluded to by Dr. Marcy, viz., the excellent care given by the nurse, with rigid asepsis in the after treatment. We all achieve better results in the hospitals because of the aseptic technic more readily maintained. On the other hand, if the sutures are placed without proper care and regard for rigid asepsis and the wound not sealed with collodion it is almost impossible to escape infection of the perineum from purulent discharge from the uterus if it be infected. In many cases of old chronic endometritis complicating lacerations of the cervix and perineum, mixed cultures may be obtained at any time. It is very difficult here, especially when the cervix is torn at the same time, not to have more or less infection, but the end results are uniformly good.

DR. C. LESTER HALL, Kansas City, Mo.: I offer, with all due respect to Dr. Marcy, an improvement on the collodion dressing. I believe that if we will use instead an application of sub-iodid of bismuth, which with water makes a paste and a thorough protection of the parts, we will not have the infections so much dreaded. It is a preparation that can be easily applied and reapplied by the nurse after douching, is not readily removed by a douche and furnishes an impermeable dressing. It is not irritating, as collodion may be.

DR. GEORGE ERETY SHOEMAKER, Philadelphia: I want to express my appreciation of improvement in personal results since learning to use the buried continuous suture in perineal work and abandoning in nearly all cases the silkworm gut suture used for so many years. If the mucous membrane of the posterior wall of the vagina is preserved, none cut away, it forms an apron clear out to the edge of the wound. All discharges from the uterus and vagina are carried over and emptied outside, so to speak, lessening the chances of infection. Unlike Dr. Marcy, I prefer to keep all fingers clean

for use in the wound. Carefully palpating the two edges of the recti, bring them together by continuous suture, then follow on down toward the surface, uniting the fascia and more superficial muscles that have been separated. Thus one gets perfect restoration and healing in practically every case. The patient has so much more comfort from not having to have the sutures removed afterward.

Dr. FRANK A. GLASGOW, St. Louis: I am surprised to hear the gentlemen speak of suppurations being so common, and also to have them deery the use of catgut. There has been much written about the repair of the perineum tending to confuse men and to make them think the operation far more difficult than it really is. Dr. Shoemaker anticipated what I wished to say, that he would preserve the posterior wall of the vagina. I do not think I have done a perineorrhaphy for twenty years in which I have removed the posterior wall of the vagina. It is an old operation, the same as Tait's, and one which I inherited from men before him, in which we simply raise up the posterior wall, extending the denudation up on either side of the vagina, up to the crest of the rectocele and then uniting the lateral parts. Under this procedure suppuration is the rarest thing in the world. There is no necessity for it, and I use chromicized catgut. Formerly I used the mattress sutures through from one side of the vagina and back again. Then when Tait taught us how to bury catgut I used that method and do not have suppuration. If a stream of water is used over the denudation down over the perineum carrying anything which should escape from the rectum downward suppuration will not occur and buried catgut may be used. There is no easier operation in gynecology than just this repair of the perineum, and every practitioner ought to be able to do it. Many men do not make a perineum. They simply denude a little and bring the skin together. You should raise up the posterior wall, extend the denudation high up into the vagina and on either side and bring the lateral walls together by buried sutures. You will thus have a good perineum and no suppuration.

Dr. H. O. MARCY, Boston: A man works best with the instruments with which he is most familiar. The two fingers in the rectum help not only in the use of the knife but in the application of the suture, making a double shoemaker's stitch. When one becomes a little used to the method one will not mind the loss of those two fingers for other purposes. I am glad to have the value of the nursing emphasized. It is a large factor after we are through with our surgical work.

The late Dr. Jenks of Detroit was the first, so far as I know, to preserve the posterior vaginal mucous membrane as he called it. I was the student of Sims and Emmet, and delighted to try to imitate the dexterity with which they used the scissors. I have seen continuous backward and forward dissection with a pair of scissors as a girl would pare an apple without the infraction of the entire process. But I found that Dr. Jenks was not removing the mucous membrane but dissecting the posterior vaginal wall. That is very thin in most instances. Near the original lesion of the parts it breaks easily. That is why I like the knife. With scissors we are apt to cut buttonholes. It is important that one make a dissection of the posterior wall of the vagina and leave it intact. It is also important that one make use of modern aseptic methods. There must be a clean vagina, a clean uterus. In most instances one curettes, sews up the laceration of the cervix and then applies the iodoform dressing in the vagina. What I like best is to use it on a wool tampon. After this is completed it is an easy matter to seal the wound with collodion, and it remains for two or three days. The vagina is literally packed with iodoform wool and that is left alone for three or four days. That is the end generally of all the treatment. The rectum is almost always packed in the same way.

No one has referred to operation for complete laceration of the anterior or posterior vaginal wall. In the old days we were all greatly troubled by vesico-vaginal fistulas. My old master, Sims, taught me the use of silver wire, and we all had great agony over it. When I operated within the abdominal cavity for bladder injury I found that I obtained recovery without difficulty. Then it occurred to me that the

reason we failed in vesico-vaginal fistula was that we had a cross-pull of the complex structures. Therefore, I separated the attachment of the vagina to the bladder, freshened the wound and then closed the bladder wall with a double continuous fine tendon suture, not unduly compressing the tissues. That, of course, is buried because the vaginal wall is closed over it, and in every single instance I have had just as easy recovery as I did when operating from within the abdominal cavity. If I could say nothing else, I should like to emphasize this point, that I believe this to be a very great advantage in my technic. It is comparatively immaterial how one applies the sutures. With coaptation, retention, and aseptic rest, good results will follow. With wounds treated in this way in my own hospital in several thousand cases there have been not 2 per cent. of failures in the last fifteen years.

PATHOLOGIC RELATIONSHIP OF ULCER AND CARCINOMA OF THE ALIMENTARY CANAL *

LOUIS BLANCHARD WILSON, M.D.

Pathologist and Director of Laboratories

AND

BYRD CHARLES WILLIS, M.D.

Assistant Pathologist, St. Mary's Hospital

ROCHESTER, MINN.

INTRODUCTORY

Any line of investigation which promises assistance in combating the spread of cancer is worth while. For, discounting to the utmost government census figures everywhere, there yet remains the facts, first, that cancer is increasing materially in relation to the total number of deaths from all causes, and, second, that it is increasing materially in relation to the total number of living. Speaking broadly, it is probably increasing more rapidly than any other of our diseases. And this increase is greatest in the most prosperous nations and in the most prosperous classes within such nations. Further, it attacks individuals at their highest productive period. It attacks particularly the primary organs of perpetuation of the individual, i. e., the reproductive apparatus. In the male approximately two-thirds and in the female one-fourth of all cancers develop in the alimentary canal, while one-half of all cancers of the female are in the reproductive organs.

It seems to us that in our consuming interest in the initial excitant or ultimate cause of cancer, there is a possibility of our losing sight of the importance of the study of the tissue conditions of the affected individual. When the relationship of bacteria to infectious disease was first brought to the attention of the scientific world for a long time the specific germ was the chief object of study. Experience soon taught us, however, that in combating infectious diseases it is even more important that we familiarize ourselves with those conditions of the body by which nature combats disease. We are apt to forget that if we knew to-day the primary irritant in carcinoma as well as we know the leprosy bacillus we might still be almost as helpless as we now are in controlling the disease. We would still be under the necessity of investigating most carefully the anatomic and physiologic condition of the tissues which permit the primary excitant, whatever its nature, to become effective.

CLINICAL EVIDENCE

From the purely clinical standpoint, probably the most salient points which present themselves in relation to tissue susceptibility to carcinoma are the following:

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Carcinomata of the reproductive organs in the female—one-half of all cancers in this sex—occur principally at the age when the reproductive organs have begun their regressive changes.
2. Carcinomata of the alimentary canal—two-thirds of all cancers in the male—follow in the great majority of cases chronic non-cancerous irritation.

ANATOMIC EVIDENCE

When once removed from the body, tumors of the alimentary canal are of relatively easy study, because of the comparatively simple anatomic relationships; the thin walls with well-defined laminae and simple glands. The lips, mouth and anus are, of course, exceptions to this. When we examine carcinomata of the alimentary canal we find them in a great majority of cases developing on epithelial tissue which has been displaced either by ulcerative changes or by diverticula. An ulcer of the mucous membrane of the alimentary canal shows within its base usually only granulation tissue, all of the tubular glands having been destroyed. At the margin of the ulcer is an overhanging border consisting of tubular epithelium which have been cut off from their connection with the outer world by bands of scar tissue.

The center of the ulcer, filled with granulation tissue, is almost always on a level with that of the normal base of the mucosa, within which is the ring containing segregated epithelium. The tendency of such islets of segregated epithelium is toward destruction by the cutting off of their blood-supply by scar tissue. In a careful study of these cell inclusions, however, we frequently find that many of the islets instead of degenerating show more or less proliferation of their cells. This is evidenced by their apparently increased number in a cross-section, by their mitotic figures and their dividing nuclei. Such inclusions are of frequent occurrence around the borders of all ulcers of the stomach, duodenum, gall-bladder, appendix and large intestine. It is probable that the proliferation of the epithelium within such inclusions is frequently stopped by the cutting off of the blood-supply, and that degeneration results. When, however, we study many lesions of this type, particularly within the stomach, we find that certain groups of epithelium show not only proliferation of their cell contents, but that the proliferating cells are infiltrating the surrounding tissues; that this is a true passage of the epithelium into the previously formed scar tissue. That the picture is not due to the presence of remains of included epithelium which has been only partially cut off from its normal site there can be no doubt in the mind of one who studies the sections with proper care. The epithelial cells which are insinuating themselves between the bands of fibrous tissue are not old degenerating cells, but are cells which are proliferating, as is shown by their staining reactions and their dividing chromatin. It is noteworthy that this proliferation is usually most marked in the portion of the epithelium-bearing ring which is furthest removed from the center of the ulcer with its scant nutrition. More than 70 per cent of all of our cancers of the stomach give satisfactory gross and microscopic evidence of previous ulceration and isolation of epithelium, while the evidence is equally clear in our cancers of the gall bladder. We have seen at no point within the alimentary canal any evidence that surface irritation, however prolonged, has anything to do with

providing conditions suitable for the development of carcinoma. It seems to be a *sine qua non* that the portions of epithelium shall be displaced from their normal relationship, and this does not occur where superficial irritation alone is concerned, but only in ulcers and diverticula.

The relationship of small diverticula of the alimentary canal to carcinoma has not been fully appreciated, partly because the presence of the diverticula themselves have been but recently called to our attention. When Drs. Mayo, Giffin and Wilson placed on record our five cases of diverticulitis of the sigmoid three years ago, there were on record only eighteen previous cases. One of these presented a carcinoma of a diverticulum. The number of cases of diverticulitis has increased during the subsequent three years until there are now on record nearly one hundred cases. We have added five new ones to our list. In these five two are cases in which the operation was made primarily for well advanced carcinoma and diverticula were found in the base of the carcinoma. The epithelium within small diverticula is frequently quite as completely occluded from connection with the interior of the viscus as is that lying at the base of an ulcer of the stomach. Here, as in the isolated islets of epithelium within the stomach, the tendency of the segregated cells is to degeneration from reduced nutrition. They do, however, occasionally proliferate greatly and, as we have shown in three of our nine cases, they may also infiltrate and thus form carcinoma. When one goes over a number of cases of carcinoma of the sigmoid one is struck with the patch-like or ring-like character of all of the lesions, except those of the most advanced type. This is exactly the sort of tumor which one would expect to find developing on isolated epithelium within diverticula, and the two tumors whose origin, as we have demonstrated, has been on diverticula, are of exactly this type. In order to show the presence of diverticula in carcinomata of the sigmoid which have advanced to any extent, it is necessary to use the utmost care in examining the specimen while it is still fresh. Sometimes with fresh specimens this can be done by very gently probing from the inner side of the tumor, or better still, by carefully slicing off the tumor from the serous surface and parallel thereto, and examining underneath each slice as it is removed. We are satisfied from our experience that many cases of carcinoma of the sigmoid and rectum have had their origin on diverticula which have been overlooked at operation, even when they were still undestroyed by the tumor.

In the last 5,000 appendices which have been removed at our clinic we have discovered twenty-two primary carcinomas. In reviewing these recently, Drs. MacCarty and McGrath have noted that all of these tumors have occurred in the tips of appendices which had been previously obliterated. This obliteration in all cases extended well proximal to the tumor, and showed the formation of scar tissue at some point proximal to the tip in greater quantities than in the tip itself. The glandular epithelium of the tip of the organ has been separated from the lumen of the caecum. Such epithelium is frequently found to show hyperplasia or adenomatous proliferation. In the twenty-two cases which we have found, however, there is much more than this, viz., an infiltration of the deeper layers of the appendix, resulting in unmistakable primary carcinoma.

In the tough fibrous stroma of the border of the lips it is difficult to make out microscopically any evidence of flat-cell inclusions. The lips of practically all adults

have been so frequently subjected to traumatic scars, ulcers, etc., as the result of nutritional disturbances that it would seem probable that such inclusions of the epithelium are frequently present. Carcinomas of the lip, however, usually come to the clinic so late that all microscopic evidence of their previous benign ulceration has disappeared, though the clinical histories recite such evidence in an unmistakable manner.

Within the mouth the relationship of ulcerating leukoplakia to subsequent carcinoma is established on a very firm clinical basis, though here, as in carcinoma of the lip, the patients most frequently come to operation at a period when all microscopic evidence has been swallowed up in the advance of the secondary disease.

To summarize, then, the results of our studies, we may say that in the alimentary canal, whatever may be the essential irritant—micro-organisms, ferment or what not—the fact remains that in a very high percentage of the cases there is microscopic evidence backing up clinical evidence that the carcinomata have developed on epithelial cells which have been previously isolated from their normal surroundings, either by the formation of diverticula or by being cut off by scar tissue in ulcer bases. This statement has in it neither support nor contradiction for any hypothesis as to the character of the essential irritant in carcinoma. Just as we must have tissue cut off from sufficient blood-borne oxygen in a punctured wound in order to permit development of the tetanus bacillus, so it seems that in the alimentary canal we must have tissue which is cut off from its relationship with the outside world in order to have the development within it of whatever may be the essential irritant of carcinoma. Whether this isolation of epithelium is a primary necessity for the formation of carcinomata throughout the body is another question. Certain it is that a similar condition exists in the female breast which is undergoing regression. Certain it is that similar conditions exist in the uterus, with its partially shed epithelium, with its frequent erosions, and with its regressing mucosa. Certain it is that a similar condition exists in the prostate as the result of inflammatory changes segregating islands of epithelium. Within the kidney true carcinomas are frequently associated with the ulcerated process secondary to nephrolithiasis, while the so-called "hypernephromata," on the other hand, are apparently the result of the proliferation of tissue which has failed to become connected embryologically with the portion of the tubular epithelium which is in direct relation with the renal pelvis. Indeed, as we look over the whole field of carcinomata we must agree with Adami that these tumors are the result of the development on either postnatally or prenatally displaced cells which exhibit a tendency to revert to the embryonic type.

The clinical bearing of all of this is in teaching the importance of the recognition and cure of those disease processes which, however benign in themselves, tend to isolate epithelium. There can be no question but that chronic ulcers of the mouth should be promptly cared for. Ulcers of the stomach should receive the most minute attention. The obliterating appendix, however innocent its look, should invariably be removed when found. Diverticula of any portion of the large intestine should be treated by complete removal rather than by a drainage of the abscesses which may be formed about their extremities. The greatest difficulty of course is in the early diagnosis, but that is without the province of this paper.

PATHOLOGIC MATERIAL STUDIED

167 cancers of lip.
40 cancers of mouth and tongue.
2 cancers of esophagus.
189 cancers of stomach.
15 cancers of gall-bladder.
22 cancers of appendix.
20 cancers of cecum.
42 cancers of remainder of colon.
67 cancers of rectum.

570

SUMMARY

Of the cases of cancer of lip 30 per cent. gave evidence of previous isolation of epithelium.

Of the cases of cancer of stomach 67 per cent. gave such evidence.

Of the cases of cancer of gall-bladder 33 per cent. gave such evidence.

Of the cases of cancer of appendix 100 per cent. gave such evidence.

Of the cases of cancer of cecum 10 per cent. gave such evidence.

Of the cases of cancer of colon 40 per cent. gave such evidence.

Of the cases of cancer of rectum 3 per cent. gave such evidence.

CONCLUSIONS

1. The relationship to cancer of simple chronic irritation of the unbroken free surface of the mucosa of the alimentary canal, as indicated by clinical data, is not readily demonstrable pathologically.

2. Scar tissue at the bases of ulcers, obliterations of the lumina of appendices, and diverticula segregate portions of mucous epithelium from the neighboring epithelium and from the lumen of the alimentary canal.

3. These portions of segregated mucous epithelium tend (a) to degenerate from pressure and diminished blood-supply, or (b) to proliferate and infiltrate the surrounding tissues, thus forming cancer.

4. These islands of segregated epithelium probably should be regarded as points of least resistance only, and requiring the presence of other factors for the production of carcinomata.

ABSTRACT OF DISCUSSION

DR. H. E. ROBERTSON, Minneapolis: We are all helpless in the presence of cancer. Sometimes we believe that malignant growths are preceded by absolutely normal structures; this morning we have had another view presented. Dr. Wilson's contribution is of great value in showing specimens which demonstrate at least one phase of the problem. The activities of epithelial cells may be grouped under two classes: first, that of function, such as secretion or absorption, and second, that of manipulation or proliferation. When for some reason or other the functional activity is checked, all the inherent capacity of the cell may be directed toward wild, uncontrolled proliferation. Such a process might be supposed to be working in ulcers and inflammatory conditions which in all probability precede many carcinomatous tumors of the gastro-intestinal tract. The functional activity is inhibited because of inflammation, and some of the cells continue to multiply unchecked by any normal balance. I do not believe that Dr. Wilson would, for a moment, claim that all cancers arise from ulcers or preceding inflammatory lesions nor would he give the impression that all ulcers of the digestive tract gave rise to carcinoma. His paper emphasizes what we have been taught for many years, namely, that some ulcers of the gastro-intestinal tract may show cancer arising on the old margins.

DR. J. N. HALL, Denver: I wish to speak about the diagnosis of certain conditions requiring gastro-enterostomy for

pyloric obstruction, and I base my remarks on a series of 71 cases in which ulcer has been found blocking the pylorus. In these cases, the patients were operated on by Drs. Freeman, Perkins, Craig, Lyman, Fleming and other Colorado surgeons. During the same time a diagnosis of peptic ulcer was made in 81 other cases, and a very probable diagnosis in 23 cases, 175 cases in all, indicating that 40 per cent. of my cases of ulcer seemed to me and to surgeons doing much of this work, to need gastro-enterostomy. I exclude here all cases of ulcer operated on for perforation or in which resection was done because of the probability of cancer, and all gastro-enterostomies done for cancer, congenital pyloric stenosis, etc. So far as I know, there is no exact parallel for the state of affairs which exists as to this diagnosis. Many physicians recognize the gastric ulcer which blocks the pylorus, whether it be by producing spasm, by its thickening effect on the mucosa, or by the production of scar tissue. But for every clinician who frequently sees these cases there are ten who practically never call on the surgeon for help in treatment. These men either do not recognize the condition or do not recognize the fact that surgical intervention is demanded. Yet many surgeons diagnose these cases and operate without either the professional assistance or the normal support of the internist. It is a strange fact that the surgeon in many of these medical cases makes a better diagnosis than the physician. A surgeon of one of the oldest and most famous hospitals in America told me a few weeks ago, when I inquired as to the treatment of pyloric obstruction, that he was ashamed to tell me how limited his experience was, since the medical men of that institution practically never referred such cases. Yet in that city another surgeon at another hospital does much of this work. There is much ground for criticism of the profession in that so much stomach work is done by so many men, but a small proportion of whom recognize the frequency of this condition, its ease of diagnosis, in most cases, the almost certainty of relief by surgical help, and above all the overwhelming evidence that the end of these patients is slow starvation or eventually cancer. From Rochester we learn that 71 per cent. of resections for cancer showed origin in an ulcer, and 68 per cent. of the resections for ulcer showed cancerous changes. Yet under the diagnosis of dilated stomach, atonic dyspepsia, gastralgia, gastrodynia, nervous prostration, etc., these patients go on toward starvation or cancer, or both. In 11 of my cases the ulcer had evidently existed for from 18 to 30 years.

While the medical men discuss the fine points of differential diagnosis, some good surgeon, or a medical man who stands daily by the operating table and sees what the living pathology of the abdomen reveals in the cases he refers to the surgeon, often intervenes and by timely operation restores the patient to health.

We found associations for the study of cancer, but allow patients with ulcer of the pylorus, the very mother of cancer, go on under treatment by alkalis, bismuth and pepsin, the latest diet, etc. knowing all the time that cancer of this region kills more people than any other form, that it is curable by operation under favorable conditions and by operation alone. I go so far as to say that I am convinced that pyloric ulcer is so likely to lead to cicatricial stenosis, if it ever does heal, or to cancer if it does not, that I personally would not submit to any but surgical treatment for such a condition, nor do I recommend prolonged medical treatment to my patients. And yet such is the conservatism in certain quarters that if a patient with dilated stomach escapes from the internist and is cured by the surgeon, the internist will almost say, as did the arrogant Viennese professor of 50 years ago when one of his patients to whom he had given a fatal prognosis recovered under a new line of treatment at the hands of one not a university professor: "You must have been treated wrongly."

DR. FRANK WILBUR FOXWORTHY, Indianapolis: I am an internist and I want to know the relationship between ulcer and cancer in relation to time; how much time elapses from the ulcer stage? I have under my care an old woman with ulcer near the pylorus of five years standing. She was on an albuminous diet for 6 weeks and then left the

hospital free from symptoms for 13 months and she now weighs 168 pounds. Am I to believe that she is in danger of developing cancer or to suffer from the thoughts of expecting it the rest of her life?

DR. D. C. WALT, Little Rock, Ark.: I should like to emphasize a point which I think might be of interest to physicians as well as to surgeons and showing that we should know our limits. I have had an epithelioma, and I feel that I have been benefited both by the general management of my case as well as by the use of the x-ray which was applied by a Chicago physician. I feel that I am fresher to-day than I was ten years ago, and I do not attribute it all to the x-ray. Every cell organism, every animal organism is dependent on a general law, for its building process; it is a matter of waste and repair, of supply and demand. When we wait until the cell is dead, whether it is from abscess of the liver or in the tubule of the kidney, or carcinoma, the cell is dead and dead forever. We as animals, have attempted to interfere with Nature's method of living. Think of the results produced by our notions which interfere with Nature's laws of waste and repair. When the child is born, the mother places a napkin on it, making a barrier to elimination. When the child becomes older he is harnessed more securely and by the time he is matured he thinks he is living within Nature's law. One man develops arteriosclerosis, another carcinoma, another tuberculosis, all coming under the disturbances of waste and repair. We must recognize sympathetic nerves and their power to control the physical conditions, when properly influenced by the electromagnetic power.

DR. CHARLES G. STOCKTON, Buffalo, N. Y.: I feel that I ought not to allow the remarks made by Dr. Hall to go without some reply. It seems to me that his attitude toward the physician and the internist in the matter of treatment of acute ulcer as well as of chronic ulcer is wrong. I have no doubt at all that we do sometimes find cancer growing on the seat of a chronic ulcer; this certainly does occur, but not so often as one would infer from Dr. Hall's remarks. I have studied peptic ulcer carefully for years and I have had recurring cases under observation for many years and they did not develop into cancer. Furthermore, it is unnecessary in the majority of these cases of ulcer of the pylorus to resort to surgical treatment except in cases having definite and positive indications. It is unfortunate that so much importance should be attached to the scar tissue; it is unfortunate that anyone should take the position that when there is a scar as the result of a gastric ulcer, the case should go to the surgeon, because it often results in the subsequent ill health of the patient. If the cases were selected by discriminating men, if only skilful surgeons operated in such cases, we then might go further and advise operation oftener. But I have seen so many evil results from the employment of surgical methods on this part of the economy that the statements made by Dr. Hall seems to me misleading.

DR. RICHARD WEIL, New York: It seems to me somewhat questionable to interpret every instance of epithelial segregation or inversion as evidence of a tendency to carcinomatous degeneration. The presence of granulation tissue seems, as a rule, to carry with it a stimulus to this very sort of atypical epithelial proliferation. Consequently it is not a rare concomitant of chronic inflammatory processes in various parts of the body. Fisher and others have been able to produce similar results by means of chemical irritants, such as scarlet red, but they have not nevertheless produced true cancers. Occasionally, of course, cancer may originate in this fashion, but to assert on the basis of these microscopic changes that the majority of ulcers show a tendency to carcinomatous degeneration is an altogether different matter.

DR. JOHN A. LICHTY, Pittsburg, Pa.: The pathology which Dr. Wilson has shown us to-day is convincing, and I believe that he has established his point. I am led to recall, however, the appearance of uterine scrapings which have been looked on as suspicious of a beginning carcinoma. In some of those cases I have sent sections to the pathologist—in one case in particular to Dr. Welch, of Johns Hopkins—

which, to me, looked suspicious; yet Dr. Welch told me it was not malignant, and explained the condition very much as Dr. Weil has attempted to explain some of the lesions which Dr. Wilson has demonstrated. The subsequent history of these cases confirmed Welch's opinion. I am afraid Dr. Hall has drawn conclusions from Dr. Wilson's paper which are not relevant to the subject. I do not believe that in all cases of gastric ulcer, and those suspicious of gastric ulcer, the abdomen should be opened and the ulcer incised. This would lead to a great amount of unnecessary surgery and would expose patients to a great risk.

It will be recalled that in only 20 of the 5,000 cases of appendicitis was malignancy found. Now, we know, of course, that malignancy in the stomach is more frequent than in the appendix. I can agree with Dr. Wilson's conclusions as he has stated them, but I would not be willing to attach the conclusions which Dr. Hall has presented to us this morning.

DR. A. JACOBI, New York: All of us I believe have seen cases of gastric ulcer and also cases of gastric carcinoma. The diagnosis of ulcer of the stomach is not always easy; it is made by different persons differently, and their statistics differ. The surgeon with statistics taken from nothing but a surgical practice, or even a surgical hospital practice, will state that carcinoma of the stomach is very frequently encountered, that it is frequently complicated with gastric ulcer, and that there is a frequent connection between the two. He cannot tell you the reality about these statistics, when he forgets or overlooks the fact that they are the bad cases that have disappeared from the hands of the general practitioner to appear in the hospital wards, and that he sees these bad cases only, and not the average ones. The surgeon will report what he has seen, and so far he is correct. On the other hand, the man in private practice who sees the poor patient with ulcer of the stomach will say that ulcer of the stomach is a very common disease, and he will offer quite different and more favorable statistics; he is the one who can tell whether the case has terminated in hemorrhage or in carcinoma. The fact is that from a large number of statistics it has been found that there is about 3 per cent. of the cases of carcinoma occurring in the neighborhood of the pylorus which are on the scar resulting from an old ulcer. I see a great many of these cases of gastric ulcer and especially among the poor, the working people, male and female, small shopkeepers, etc.; these poor people work hard and may suffer weeks and even months before they consult a physician. Many will take care of themselves and they at times will recover in large numbers. We should compare the sources from which these people come to us. The general surgeon, the surgeon in private practice, the physician, the so-called internist, the physician who has a consultant practice only, or a large practice among the rich, the physician who has a large practice among the poor, all these men will give different statistics, and this is a point which we should all be made aware of. The general practitioner has the more correct statistics. I once suggested that 500 general practitioners should club together and all their cases of gastric ulcer with their outcome be collated and compared.

DR. HARVEY G. BECK, Baltimore: If we accept the fact that carcinoma of the stomach results from ulcers, then with a view of preventing the disease, we should consider the origin of the ulcer, and treat the underlying cause. We all recognize that there are different forms of ulcer of the stomach. For instance, we have the chlorotic form which occurs in girls. If the chlorosis is early diagnosed, and treated, we may prevent ulcers, and indirectly carcinoma. Another form of ulcer is the so-called catarrhal ulcer, which results from a chronic acid gastritis. Here again, if we treat the underlying condition—acid gastritis—we may prevent the ulcer, and the tendency to carcinoma. A third group may be classed as traumatic ulcer. These ulcers are due to an injury or irritation and are frequently the result of occupation. These cases certainly have a greater tendency toward the development of carcinoma, and if they do not yield readily

to medical treatment should be treated surgically in order that carcinoma may be prevented.

DR. G. C. SMITH, Boston: During the last 10 years only 2 patients with carcinoma developing on the site of an ulcer of the stomach have appeared in my office. Of the other cases I have had under observation, none has so far developed into cancer. I do not think we are justified in treating these patients along the lines suggested, because there is a possibility of cancer developing on old scar tissue, any more than is the man who treats skin disease who goes on and feels that he must treat the patient indefinitely with mercury. The idea prevails that such a patient has practically recovered from syphilis and that he must be left alone until something develops later, when a short treatment should again be given. I can easily understand the position assumed by Dr. Wilson in his paper. As Dr. Jacobi has so well expressed it, any statistics to be of value depend quite as much on our interpretation of them as upon the mere statement of the anatomic findings. One man has reported many patients with cancer of the stomach operated on, and in many of them he reports that the cancer has developed on an old scar tissue. He is justified in reporting such cases. But he has not seen cases as have Dr. Jacobi, Dr. Stockton, and others, in which the patients were not operated on. Some statistics are given which apply only to those patients who developed cancer; not all individuals, however, develop cancer on scar tissue. It must be remembered that 50 per cent. of patients with tuberculosis recover; this is the report from Prof. Kolisko of Vienna, where it is said that there are more cases of tuberculosis than in any part of the world. But Prof. Kolisko does not state that these patients do not subsequently develop tuberculosis. We cannot state positively that a person has been permanently cured of tuberculosis; we do know, however, that he may become apparently well. This is our interpretation of the facts.

DR. FRANK SMITHIES, Ann Arbor, Mich.: I wish to act as a sort of mediator between Dr. Stockton and Dr. Hall. There is a middle ground in the consideration of gastric ulcer and gastric cancer, that is, in regard to the prognosis, whether medical or surgical, as well as in the treatment. It depends to a large extent on the location of the gastric ulcer. I think that it is poor practice to hand these patients over to the surgeon for exploratory operation, or operation of any kind, without having at least made an attempt to determine the position of the ulcer and its effect on the motor power of the stomach. If an ulcer be situated near the pylorus and we have every reason to believe that it has healed, with a resulting scar which produces a certain amount of obstruction to the free emptying of the stomach, I think it is an extremely unwise practice to treat such a patient for a gastric ulcer indefinitely; he is bound to become a chronic dyspeptic when by an operation in the hands of a competent surgeon he can be made a useful citizen and not be left a chronic invalid. Ulcers seem to be very favorably situated for the development of carcinoma when placed where they are constantly subjected to irritation. On the other hand, it is a fault of the internist to recommend operation in all cases of simple ulcer situated in any part of the stomach which has no influence on the stomach so far as its motive power is concerned. Of course in all cases one must make an exact diagnosis. I wish to call attention to the constant and repeated examination of the stools for occult blood, not making a haphazard examination for this occult blood, but making a careful and painstaking examination of the stools that have been properly prepared for such an examination, that is, after an absolutely meat-free diet for at least three days. Another point is to examine the blood serum carefully with the idea of discovering the hemolytic reaction. This is a point which I will not debate at present. However, in carcinoma we may expect positive reaction; whereas in ulcer we do not. Again, one might speak of a very careful examination of the interior of the stomach by means of the gastroscope, but always in the hands of an expert.

DR. THEODORE POTTER, Indianapolis: It seems to me that in the discussion so far we are hardly fair to Dr. Wilson. We seem to have engaged in a general quarrel as to the diagno-

sis and treatment of gastric ulcer, with which he really had nothing to do. He comes to us presenting a careful pathologic study which he hopes may throw some light on the question of the factors which enter into the development of carcinoma. He has shown us that in a considerable proportion of the cases in which the disease has developed, and which have followed ulcer of the stomach, certain things take place and which are very significant. We must recognize them as being significant too. Dr. Wilson has presented studies which certainly will throw some light on this problem as to what is the cause of gastric cancer. With regard to the diagnosis and treatment of ulcer of the stomach, and the question as to what we are going to do about it, this certainly is not Dr. Wilson's affair; that is our quarrel. But please let us be just to Dr. Wilson and show appreciation for the work that he has done and is doing for us.

Dr. LOUIS B. WILSON, Rochester, Minn.: No doubt there are cases of cancer of the alimentary canal that have occurred without any previous epithelial segregation. We have one such, a case of carcinoma of the stomach. We have also 5 cases of carcinoma or ulcer of the stomach in which there is a proliferation, or beginning inversion of the epithelium, but I am not prepared to say that they are cases of carcinoma. Every case that I have shown to-day and 183 out of our 189 showed carcinoma in the glands or walls of the stomach. From a pathologic standpoint we are changing our methods of diagnosis. We used to wait until a "lump" was discovered before we diagnosed the case as one of carcinoma of the stomach. This we no longer do. We should not criticize Dr. Hall too severely for his statement that 68 per cent. of the cases resected for ulcer showed cancerous changes. Few known ulcers are excised and there are many in which the surgeon is doubtful as to the diagnosis. The relationship between carcinoma and ulcer so far as we can show is that in many chronic ulcers there is a segregation of epithelium on which carcinoma may develop. Not every person who is exposed to typhoid develops that disease; nor does every person who has been exposed to diphtheria develop diphtheria. The same statement may apply to epithelial segregation. But when we do encounter carcinoma, in the majority of cases there will be found to have been previous epithelial segregation. As to what shall be done with those ulcers, that is for the surgeon, and not for the pathologist, to decide.

AN IDEAL OPERATION FOR TOTAL PROLAPSE OF UTERUS *

SAMUEL WYLLIS BANDLER, M.D.

Adjunct Professor of Gynecology, New York Post-Graduate Medical School and Hospital

NEW YORK

There persists, especially after several or instrumental labors, an elongation of the round ligaments and of the six consecutive-tissue ligaments associated with the uterus, and more especially the ligamenta cardinalia. There is deepening and sinking of the peritoneal pelvic recesses anterior and, especially, posterior to the uterus. Since the normal anteverted or anteflexed position of the uterine fundus is maintained only if the cervix is high up and far back, such descent of the cervix and fornices permits the fundus to drop back into retroversion, unless there be present unusually short and muscular round ligaments.

Slight ptosis of the uterus may occur with the fundus in anteflexion or anteversion, but marked ptosis of the uterus implies an associated retrodeviation. A retroversion or slight retroflexion permits abdominal pressure, among other accessory factors, to cause a ptosis

of severe degree. Ptosis does not occur if there are no lengthened ligaments; if the broad ligaments are elastic or sclerosed; if the uterosacral ligaments are short; if there is no tugging by a loosened vagina; if there is no atrophy of the perivaginal tissues; if there is no injury to the levator ani muscles, etc.

If a severe degree of ptosis carries the uterus down no further than to the vulva, such a hysteroptosis may be defined by the term "descensus uteri." If the uterus descends beyond the vulva, the condition is called a prolapse. With marked ptosis of the uterus there is descensus vaginae. The anterior and posterior walls of the upper vagina descend in association with any marked descent of the uterus. The nearer the portio uteri approaches the vulva, the more is the vaginal canal shortened until, in the more extreme cases, it too finally lies outside the vulva.

Injury to the fibers of the levator ani muscles, even when the perineum is not torn; results in a very flabby vulvar outlet, and when the perineum is torn, in a hernia of the rectum (rectocele). Many cases do not result in more than uterine ptosis, or retroversion or retroflexion, even when they develop cystocele, or both. Loss of the support which the levator ani furnishes the vagina may be of importance. In many cases the uterus is elongated, much enlarged, the cervix is thickened and hypertrophic and the vaginal mucosa very thick. There is subinvolution and, at times, atrophy of the elastic perituterine and perivaginal tissues. There is not infrequently associated with this condition, even in cases in which labors have not been numerous or instrumental, a state of general elasticity associated with flabby subinvolved abdominal walls and with varying degrees of gastropptosis and enteropptosis. What effect may persistence of retroversion and descent associated with intra-abdominal pressure and accessory pressures have in such cases? It leads to further uterine descent, and then, if perivaginal atrophy, large vagina and thickened mucosa are present, we observe further vaginal descent; (1) vagina pushed down by uterus; (2) vagina pulling down uterus; or (3) vaginal descent occurring simultaneously with uterine descent, but primarily independent of it.

The pathologic factors may be grouped as follows:

1. Tendency to inelasticity.
2. Labor injuries, especially if repeated.
3. Subinvolution; ligaments, uterus, vagina, etc.
4. Primary ptosis leading to retroversion. Since retroversion is present, attention has been paid to the displacement, and while this is an important pathologic factor, the elements of subinvolution, injury to the various muscles, atrophy and predisposition are overlooked.
5. Posterior enterocele and large descended fornix.
6. Large vagina.
7. Vagina loosened, giving no support.
8. Loosened vagina, actively tugging on the uterus.
9. Bladder torn from its fastenings.
10. Splanchnoptosis and intra-abdominal pressure.
11. Vocation.
12. Age. Most of the extreme cases occur after the menopause age, when there is great atrophy of the elastic fibers.

In the most extreme cases all union of the vaginal canal with surrounding connective and elastic tissues has been dissolved; all relations of fornices to normally situated peritoneal or uterosacral structures has been altered; all attachment of the uterus to fixed points of the pelvic wall have ended in tremendous elongation or atrophy.

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Surgically, therefore, we have to take into consideration the following points:

1. Bladder and anterior vaginal wall.
 2. Retrodeviation.
 3. Elongated uterus, hypertrophied cervix.
 4. Roof of vagina, which should be restored to its former elevation.
 5. Posterior enterocele.
 6. Capacious vagina.
 7. Descended vagina.
 8. Rectocele and perineum.
- } Levator ani.

The first step in the operation is based on the vaginofixation operation of Dührssen.

The complete separation of the bladder¹ from its attachment to the cervix to the anterior wall of the uterus, to the lateral margins of the lower part of the uterus and to the anterior fornix and anterior vaginal wall, permits this organ to shrink up to a very small size and permits of its dislocation into any desired relation to the uterus. It is, therefore, obvious that, if the uterus is now attached by its anterior surface to the vaginal flaps, so that the fundus lies up behind the symphysis, the bladder must of necessity then rest on the fundus and posterior wall of the uterus and can never again come into contact with any area of the anterior vaginal wall. It is desirable, before attaching the uterus, to resect such an area of the anterior vaginal flaps as will make a taut anterior vaginal wall, a wall of such nature that it neither permits the fundus to sag down into the vagina nor forces it too far back from intimate relation with the symphysis. In this new position of the uterus, the bladder assumes a new and permanent relation to the posterior uterine wall. It is not necessary, nor do I deem it advisable except in rare instances, to sew the peritoneum on the posterior wall of the bladder to the peritoneal covering of the posterior wall of the uterus at the level of the internal os.

Resection of the flaps and fixation of the uterus to the anterior vaginal wall may be carried out at this stage but fixation of the uterus to the resected flaps may be better allowed to wait until the next two steps of the operation have been completed, namely, the amputation of the cervix and the correction of the posterior enterocele. When the uterus is fixed to the anterior vaginal wall, I pass four sutures, two of heavy braided white silk and two of No. 3 chromic, through the edges of the anterior flaps and through the upper part of the uterine fundus. The fixation is best allowed to wait, but the four fixation sutures are carefully passed through the fundus, their ends are grasped by an artery forceps, and are subsequently threaded and passed through the vaginal flaps after the next two steps have been carried out.

A high amputation of the enormously hypertrophied cervix is now in order. The fundus is replaced within the pelvic cavity, with or without fixation to the flaps, and the cervix is pulled down beyond the vulva and lifted up toward the urethra. A transverse incision is made through the vaginal mucosa at as high a point as possible without entering the cul-de-sac of Douglas; the lower edge of the incision is grasped with a mouse-toothed forceps; and the index-finger covered with gauze, sometimes aided by short snips of blunt-pointed scissors, separates the vaginal wall from the posterior wall of the cervix up to the peritoneal fold of Douglas, and continues to dissect this peritoneal fold upward for a considerable distance from the posterior wall of the

uterus. We still have the lateral wall of the cervix covered by a bridge of vaginal mucosa; this bridge is incised with scissors down to the actual structure of the cervix, first on one side and then on the other, and, with its submucous connective tissue is peeled away from the cervix by upward rubbings of the gauze-covered thumb. It peels away from the cervix smoothly and easily up to the uterine arteries. In this maneuver, as well as in the dissection of the posterior vaginal wall, there is considerable oozing, which is of minor importance. Side retractors are introduced there, if necessary, the bladder is held out of the way by an anterior retractor and the cervix is amputated at the level of the internal os by the aid of scissors. If this amputation is carried on from one side to the other, or from the anterior wall of the cervix down through the posterior, cutting of the uterine arteries should be avoided. As soon as the canal of the cervix is invaded the thick anterior lip should be grasped with single-bladed volsellum.

After amputation of the cervix, the uniting of the vaginal mucosa around this new external os is begun, first at the posterior wall. No. 3 chromic catgut sutures being used and the vaginal mucosa being caught at least three-quarters of an inch from the edge in order to cover thoroughly the denuded lower end of the uterus. After the first suture is applied and tied, the others are applied close to this one, first on one side and then on the other, care being taken to take up the vaginal mucosa snugly, so as to allow of no reefs or pleats. In this way the surplus of the posterior fornix and of the two lateral fornices is done away with. The sutures are then applied to the lateral wall and then to the antero-lateral walls. A large surplus of vaginal flaps is noted, which consists of the originally dissected anterior vaginal flaps plus the surplus gained from the posterior and lateral fornices. The flaps are drawn, first one and then the other, over to the opposite side, and a very large triangular area is cut away. Now the uterus may be attached to the remaining vaginal flaps, each of the four fixation sutures which have been applied in the uterine fundus being threaded separately and carried through the vaginal flaps near their upper end. These may now be tied, bringing the fundus into intimate relation with the newly formed anterior vaginal wall. The flaps below the fixation sutures are then united by interrupted sutures of No. 3 chromic, which pass through the anterior uterine wall at the same time; or else the tying of these sutures may be left until the complete dissection of the rectum from the posterior vaginal wall has been completed, for, if in some instances these fixation sutures are first tied, it is a more difficult procedure to carry out a thorough dissection and resection of the posterior vaginal wall.

The next step of the operation consists in a high colpoperineorrhaphy which includes an absolute separation of the rectum from the posterior vaginal wall to within $\frac{1}{2}$ to $\frac{3}{4}$ of an inch of the newly formed external os.

Two single-bladed volsella are attached to the lateral margins of the vulva at a point which is to constitute the lower end of the posterior vaginal wall and the highest point of the new perineum. These are drawn apart (before this an intra-uterine strip of gauze is introduced); and a pair of curved scissors cuts a wide tape-like strip from one volsellum to the other along the lower edge of the exposed vaginoperineal junction. Three or more heavy artery forceps are applied to the

1. The method employed in the separation of the bladder has been described in the *International Journal of Surgery*, May, 1909.

skin edge after this strip has been cut away and are allowed to hang down so that, by their weight, a denuded area half an inch in width is apparent. The upper edge of this denuded area is picked up with a mouse-toothed forceps, and a sharp knife begins the dissection of this thick posterior vaginal wall from the underlying, readily bleeding connective tissues. After this dissection has been well begun from one volsellum to the other, three or more artery forceps are applied to this upper flap, the forceps are grasped in the left hand and the fingers are placed behind the flap and the separation is continued with the knife from the underlying tissue, and then continued by the index-finger covered with gauze. After the preliminary dissection with the knife has been well started, the separation goes on easily, occasionally aided with the knife or with blunt-pointed scissors, the operator being extremely careful to avoid cutting into the rectocele. Oozing is fairly brisk, but no attempt to check it with artery forceps need be made. The dissection should extend very far laterally, especially so into the lateral sulci in which rest the separated levator ani muscles. After the flap has been thus separated upward for a distance of two inches, it is pulled down taut and then bisected along the median line as far as the separation has been carried. Artery forceps are then applied to the highest points of these flap edges and the separation from the rectum upward and laterally is continued. As the separation extends higher the flaps are bisected in continuity and artery forceps are applied high up in succession. In this manner, the entire posterior vaginal wall is separated to within half an inch of its upper limit and very well into the lateral sulci of the vagina. The flaps are then drawn down, first on one side, and then on the other; a large area is resected beginning at each volsellum and extending upwards to the highest point of the dissected flaps.

If the uterine fixation sutures have not yet been tied, they are tied now, and the union of the edges of what now remains of the posterior vaginal flaps is begun with heavy chromic catgut beginning at the highest point and gradually approaching the perineum. Occasionally, one of these sutures is made to catch the connective tissue over the rectocele in order to reef it upwards. As a rule, this is not advisable, as pockets may be formed, but with each successively applied suture the rectocele is pushed upward by a blunt-pointed instrument. After several such sutures have been tied, it will be noted that the vagina has been reduced to a canal of very small caliber, and this part of the vagina may now be gently packed with iodoform gauze. We now have left a large denuded area with the outline of a rather high colpoperineorrhaphy and some of the bulging rectocele at the lower area still remains to be dealt with.

Since the rectocele is a hernia through separated or torn levator ani muscles, these or the fascia which covers them must be brought together in such a fashion as to lie between the new vagina and the rectum and hold the rectocele permanently in check. Inasmuch as the healing of such a large denuded area is promoted to a great extent by the use of the smallest possible number of sutures, I use for the perineorrhaphy with the very best results a No. 4 chromic catgut suture passed in figure-of-eight fashion and constituting a single stitch. A very long, heavy, slightly curved needle is used; the left index-finger is introduced for control into the rectum so that the needle may at no point enter the lumen. The highest area of the remaining denudation is brought into view by a pair of forceps applied to the upper

angle; that is, to the last-applied chromic suture which united the newly formed posterior vaginal wall. The needle, introduced on the left side one-half an inch or more exterior to the volsellum, goes in deeply through the lateral area of the denudation under the levator ani muscle. It is then continued up along the left lateral edge of the denudation close along the vaginal mucosa and comes out above the last applied chromic suture, now held by an artery forceps. The needle is pulled through and with it the chromic catgut. It is now introduced on the other side of the median line and passed down between the exposed connective tissue and the rectal mucosa over the finger in the rectum half-way between the median line and the volsellum on the right side. As the needle passes lower down and gets within an inch of the skin, it is passed deeply through the tissue coming out half an inch from the skin margin. The needle and chromic catgut are now pulled through and are passed in the same fashion, but from below upward, midway between the median line and the volsellum on the patient's left side. It is then passed upward, the point of the needle being controlled by the finger in the rectum, and makes its exit at the upper angle of the denudation through the vaginal mucosa. It is then introduced on the other side of the median line, passes under the mucosa on the right lateral edge of the denudation until the point reaches the depth of the right lateral sulcus, and is thus passed deeply under the levator ani muscles and out external to the right volsellum half an inch or more from the skin edge. The needle and chromic catgut are then pulled through.

In order to make the union of the posterior vaginal wall more perfect, three chromic catgut sutures are passed (but not tied) through the edges of the mucous membrane, forming the lateral margins of the denuded area and out through a corresponding point on the other side. These are grasped by artery forceps each one separately. Sutures are now passed to unite the levatores ani of the two sides and form a bridge which is to restrain firmly the rectocele. One, two or three chromic sutures are passed by a well-curved needle deeply through the lateral sulcus of one side in which rests the levator ani and its covering of fascia and, then, through the other side in the same fashion. I have not found it necessary to dissect out through the fascia any muscle bundles of levator ani muscles. These one, two or three sutures are now firmly tied, and their influence in pushing up and holding back the rectocele is readily apparent. These are the only buried knots in this method of perineorrhaphy.

A pair of artery forceps is now applied to the middle point of the skin edge, the two ends of this long, single-stitch chromic suture are pulled on in seesaw fashion, gently but firmly, and that part of the single-stitch suture which has passed from one side to the other over the skin edges is seen to take its place at a point almost midway between the ends of the suture held in the hands and the artery forceps applied to what is now becoming the lowest point of the external perineal wound. When the two ends have been thus pulled on, the two lateral sides of the perineal denudation come together in absolute contact, and a triple knot is tied and cut; the three chromic sutures which were passed and held by a forceps are tied. They unite the lower end of the posterior vaginal wall.

Two or more chromic sutures are now introduced in the perineum itself to bring the skin edges nicely together, and the patient is catheterized. Strips of iodo-

form gauze are tucked into the vagina, and the sphincter ani is given a most thorough stretching. Then iodoform gauze is applied liberally over the vulva and perineum, and is renewed with sufficient frequency to keep this area dry. The perineum is douched several times a day, especially after catheterization or defecation, with a pitcherful of sterile aluminum acetate solution. Catheterization is continued for three or four days and the patient is then allowed to void, if she can. The bowels are permitted to act whenever the patient is so inclined, otherwise, medicine is administered by mouth on the third or fourth day.

The intra-uterine strip of gauze which is usually marked by having a piece of chromic catgut tied around the end is pulled out without disturbing the vaginal packing on the third or fourth day. The vaginal packing of iodoform gauze is allowed to remain from five to eight days. The operation is attended with a minimum of shock, the pulse-rate in very few instances being over 90 at the completion of the operation.

134 West Eighty-seventh Street.

ABSTRACT OF DISCUSSION

DR. J. H. CARSTENS, Detroit: I should like to ask Dr. Bandler how old these patients are that he operates on, generally?

DR. S. W. BANDLER, New York: From 37 to 78. The youngest is 37.

DR. J. H. CARSTENS: That is the point that I was going to bring out. This is an operation on the order of the old operation of Martin of Berlin, of Mackenrodt and of Duhrssen. I do this operation once or twice a year because the women are young. They are in the child-bearing period, and anxious perhaps to have children, and I endeavor in every way surgically to save that capacity. But when a woman is over forty, if she is past the menopause, or if she is seventy-five, why in the name of conservatism should anybody try to devise and subject a woman to an operation that takes an hour and a half to preserve a little picayune piece of uterus? When you have a good for nothing piece of uterus, have sliced off a great piece of the cervix, have taken out the tubes so that she cannot become pregnant, then you preserve this little piece. What for I don't know. In this kind of a case you can do all kinds of plastic operations, without benefit. In such a case I just cut around the uterus, take it right out, stitch the two broad ligaments together, and make a little flap. The whole thing can be done in fifteen or sixteen minutes, with good results, and the woman is not subjected to an operation which takes an hour and a half or two hours.

DR. J. RIDDLE GOFFE, New York City: I quite agree with what Dr. Carstens has said in regard to the removal of the uterus. In all these cases in women approaching the menopause, or afterward, it is my invariable rule to remove the uterus. I see no reason for keeping it. It shortens the operation very much and makes sure of good support from the broad ligaments.

The point I would criticize in Dr. Bandler's operation is that he separates from the cervix at either side the strong structure at the base of the broad ligaments, viz., the fibromuscular structures called the cardinal ligaments. Unless that support is retained, even though you do as complete an operation as has been described, sooner or later that little piece of uterus is going to come down. No matter how thoroughly the perineum is built up or how securely the fundus is stitched to the anterior vaginal wall, unless, as I say, these cardinal ligaments and the round ligaments are preserved and support from them secured, sooner or later the vagina will turn itself inside out, and while the fundus will not be seen at all, the cervix will come down and drag the bladder after it. I have seen such conditions after operation. There may be some cases, as Dr. Carstens says, of women who desire to have children, in whom it is well to pre-

serve the uterus. I have done the operation with that intent. After the uterus is removed my method is to stitch together the broad ligaments from either side across the pelvis, commencing with the round ligaments, carrying my sutures down the full width of the broad ligaments, including the cardinal ligaments. Upon this plane of tissue I spread out the bladder, stitching it firmly at three points, thus hanging it there and securing its support from above. The fascia lata and anterior vaginal wall are then trimmed off and stitched to fit snugly the base of the bladder. It is important to relieve the rectocele. A rectocele, if continued, is bound to pull the uterus down. In a rectocele we have introduced a new force which is not there naturally at all, a pulling force that drags down whatever is above and unless we repair the floor of the pelvis the prolapsed condition is reproduced. My method of doing that is to start from above where I have cut away the peritoneum posteriorly to the cervix, dissect down a broad piece of tissue the full width of the rectum, clear down to the vulva and out on either side to get hold of the levator ani muscles. Where a large rectocele is present I plicate the rectum, taking in the slack in its longitudinal axis, and then bring together the levator ani muscles from either side in front of the rectum to restore the floor of the pelvis.

DR. F. F. LAWRENCE, Columbus, Ohio: The questions occur to me: Why do we have prolapse? Why is it that in quite a goodly number of women who have had their perineums torn almost to the rectum they go on for years without even a slight descensus? It seems to me that when we start on the theory of building up from below in a case of complete prolapse or any other marked descent of the uterus we are getting the cart before the horse absolutely. In the first place, a marked retroversion is a physical impossibility, much more is a prolapse an impossibility, so long as the broad ligament is sufficiently tense to sustain the weight of the abdominal contents, not only against normal weight, but against deep inspiration or pressure about the waist from corsets or from clothing. And we may repair from below all we please but we have not relieved the ptosis within the abdomen and consequently the weight of the entire abdominal contents will be on the top of our downward repair and sooner or later with even no recurrence of the prolapse of the rectocele and the vesicocele we will have the women in constant pain because of pressure on the compressed scar tissue. I do not believe (as Dr. Carstens has just so emphatically said) that we are justified in doing any prolonged tedious plastic operation creating an enormous amount of scar tissue which never amounts to anything anyhow, leaving the real cause of the difficulty which lies above. We must restore the tension of the broad ligament to sustain the contents of the abdomen first. Then simply by the repair of the rectocele and the cystocele we shall render all the service we are able to do.

DR. J. M. BALDY, Philadelphia: This operation does not deal with the essential point of prolapsus uteri. A nice operation is done on the vagina but nothing is done after the uterus is put back into the pelvis to push it up to the normal height and to hold it there. If this is true you fail in everything, because all the pressure that tears the uterus loose will still be operative. Any operation that fails to deal with that *per se* condemns itself. The amount of denudation done is simply enormous. Passing the fingers into the rectum with or without gloves—and gloves make them dirtier than without—you add to the chance of infection.

DR. S. W. BANDLER, New York: I am not at all worried by this tirade. I have not come here and presented to you an idea. I have been working on this vaginal route for fourteen years. I tried to cure these patients originally by a simple vaginal fixation and found it was by no means enough. I added to that the high amputation of the cervix, and found that was not enough. I tried amputating the cervix and special method of getting the two large flaps before fixing the fundus in front. That was fine, but still not enough. But since I diminished the caliber of the vagina and did a high perineorrhaphy not a case has recurred. Where would we be to-day in surgery if its great men said "Don't do this or that operation because it is a long one or a bloody one?" When men like Dr. Baldy talk this way it is child's talk. These pa-

that one cannot say with certainty whether the sounds are not carried over from the right side. By auscultation one can follow the trachea to the bifurcation, and the right bronchus on down into the lung. All sounds cease in the left bronchus at the bifurcation.

March 1: Lung findings. Picture entirely changed. Breathing excursion the same on both sides. Rales the same on both sides.

Fifth Bronchoscopic Treatment.—Interval Examination.—March 1, at 6 p. m.: Time of treatment, 10 minutes. Morphin, 0.01 gm. Mucous membrane was very slightly swollen, with scattered masses of thin white mucus. Bifurcation at 29 cm. absolutely normal in appearance. One can pass the 7.5 tube easily into the left bronchus, and all seems normal even in the smaller branches. No contractions visible. Right bronchus and smaller branches seem absolutely normal in appearance. No contractions. The mucous membrane on both sides was thoroughly swabbed with 20 per cent. cocain solution, and the finer branches sprayed with same solution. X-ray picture taken after treatment shows only packets of glands along vertebrae, and a string on the left side reaching upward from the heart.

March 2: Attack. No morphin.

March 3, 11 p. m. to 2 a. m.: Severe attack. Morphin, 0.01 gm.

March 4, 2 to 8 p. m.: Severe attack.

March 5: Light attack.

March 6: Light attack.

March 7: Severe attack.

March 8: Severe attack. Patient discharged at her request.

COMMENT

In reviewing the details of this history there are certain points which seem to me of great importance. We have a case complicated by many factors—hysteria, tuberculosis and severe accessory cavity disease. The asthmatic attacks were of great severity; the patient was obliged to use morphin for years. The successful treatment of the accessory cavity trouble had no influence on the course of the disease.

The first bronchoscopy relieved the lungs of a great mass of mucus. I doubt very much, on account of the amount of secretion present, whether the cocain had any effect at all. The patient was evidently very much relieved, more so than by other form of treatment up to that time. She herself asked for another treatment.

The second bronchoscopic treatment was carried out without difficulty. No secretion, no redness, no swelling and no contractions were noted. Here the conditions were more favorable for the action of the cocain. The ordinary dose of cocain is given as 0.05 gm., which is 5 drops of a 20 per cent. solution or about as much as one applicator would carry. Sixty drops were used on the applicators and, in addition, 0.5 c.c. of a 20 per cent. solution was sprayed into the finer bronchi. Nearly twenty-two times the maximal dose was used and no effects of the drug could be noted. The pulse was not accelerated twenty beats, either by the cocain or by the procedure, which lasted nearly twenty minutes. Was the cocain absorbed as such or did it exercise some local effect on the nerve endings which would account for the subsequent great improvement? From December 4 to the latter part of January of the following year the patient was practically cured. She had no attacks, gained in weight and appetite and considered herself cured. Whatever the cause of the improvement, it seems to me that the treatments were more than justified.

The patient's indiscretion following the death of her father was too much of a strain for her poorly-balanced nervous system. All conditions were most favorable for a recurrence of the attacks, and they recurred, but, as

the subsequent bronchoscopic examinations showed, they were of an entirely different type and far less severe than formerly. Whether these spasmodic narrowings or clonic cramps of the musculature of both the large and small bronchi are typical of a certain type of asthmatic attack I do not think that we are in a position to conclude from the fragmentary observations which we now have at our disposal. In a later case, which I shall not now report, I saw nothing of them. So far, observations are too few and the pathologic picture too changing to allow us to form any definite ideas. I have reported this case in the hope that it will stimulate some one to extended experiments.

The third bronchoscopic examination was again carried out during a severe attack. Here a great surprise awaited us. Instead of finding the bifurcation at 28 cm., where it normally belongs, we were obliged to carry the tube on down to 32 cm. No explanation suggested itself. It seemed that this bifurcation was much smaller than usual; it was certainly somewhat contracted, and the mucous membrane, as far as the eye could see, was not reddened and not swollen. My first thought was that I had overlooked the condition at the first examinations, and that it was some anatomic abnormality. I also considered the possibility of having in some way shoved the lungs bodily down with the larger tube. I was entirely unable to offer any sensible explanation to the clinicians present, and I felt that I was facing some problem which I determined to clear up at the first opportunity.

The fourth examination was carried out eight days later, during a severe attack. I was prepared, after thinking over the curious conditions found at the previous examination, to pay especial attention to the region at a depth of 28 cm. As I have already said, at 29 cm. I found a white scar-like change in the mucous membrane, in the middle of which was a small opening about 3 mm. in diameter. The sound passed readily into the left bronchus and the scar-like tissue did not feel at all swollen to palpation but hard. There could be no shadow of a doubt as to the correctness of the observation. It was demonstrated to all present, and in the discussion which followed, bearing in mind the previous severe attack of diphtheria, we were inclined to regard it as a cicatricial contraction at the beginning of the left bronchus, a conclusion which entirely invalidated the observations at my first two examinations. In looking up the literature on the subject, no similar case was to be found, and nothing would satisfy me except another examination.

I was now convinced that I had found the true cause of the trouble and immediately began preparations to carry out a course of dilatations of the bronchus similar to that used by Killian in the removal of a foreign body situated under a stricture.

A careful examination of the chest, carried out a few days later during an attack of unusual severity, seemed to confirm our findings. The left lung seemed completely out of use, and one could determine exactly by auscultation the point of constriction.

Three days later an examination was again made in an interval between attacks. The findings were almost reversed. Both lungs functionated equally and no trace of a stenosis was to be found by auscultation. By this time my suspicions were aroused as to the true state of affairs, and the last bronchoscopic examination, which was made while the patient was free from an attack, showed a per-

fectly normal mucous membrane, with no signs of contractions either in the left or the right bronchus.

The conclusion was obvious; the patient was suffering from a spasmodic closure, or, better, a tonic cramp of the bronchial musculature, confined principally to the beginning of the left main bronchus, but also plainly to be seen in the deeper branches of the right bronchus.

That this cramp was not present at the first two examinations I am positive. That it was present at the second two examinations I am equally positive; and, besides, it was demonstrated to the many onlookers. And, finally, that the bronchus was again normal at the last examination was proved by the fact that the tube was passed down both sides.

In conclusion, it is interesting to note that the greatest relief occurred after the first two treatments. The relieving of the lungs of the enormous mass of mucus by the introduction of the tube seemed to be the determining factor in the first treatment. The period of forty days' relief following the second treatment might be credited to the combined effect of the dilatation, which I am convinced plays an important rôle, and to the local action of the cocain. How this local action is to be explained I am at a loss to say. I do not think that it is due to the absorption of the drug as such, for I have not yet seen any symptoms which would point in that direction. I am inclined to believe that asthma is a nervous reflex affection, and that the cocain exercises an effect analogous to the favorable action of that drug when applied locally in the nose during an attack of dysmenorrhea.

CONCLUSIONS

Combining and comparing my results with those of Notowny and Galebsky, I think that I am justified in drawing the following conclusions:

1. It is possible in a young adult to have an almost complete closure of a main bronchus, due to a tonic cramp.

2. Notowny's conclusion that the theory of bronchial spasm is false is disproved in this case.

3. The complete cures in some cases and the long period of relief in this case seems to indicate that the treatment of spasmodic asthma by the methods elaborated in this paper is worthy of more extended investigation and should be given a trial when all other methods have proven of no avail.

4. There seems to be no one bronchoscopic picture characteristic for an attack of spasmodic asthma. We may have normal mucous membrane, spasms and contractions of the large and small bronchi, and redness and swelling, alone or combined in the same case.

5. Tuberculosis, heart disease, slightly scoliotic spine, great weakness and age seem to offer no contraindication to the use of this method.

209 Post Street.

ABSTRACT OF DISCUSSION

DR. E. FLETCHER INGALS, Chicago: I have not the enthusiasm of Dr. Horn in reference to bronchoscopic treatment; I do not agree with him that there is no contraindication to the use of this method of treatment. Some men who have great skill in this line can examine patients without much difficulty and without ill effects, but it is equally true that in a large number of cases bronchoscopy is followed by serious results. Von Eicken, in an exhaustive report to the International Medical Congress in Budapest, 1909, records 308 cases of bronchoscopy for foreign bodies, collected from every available source, including the literature and personal

communications. Five of these cases he leaves out for reasons not explained; but in 303 there were 40 deaths or 13.20 per cent., the fatalities being considerably more numerous in young children. It is not possible to get accurate statistics, for most unfortunate cases are not reported, but I am under the impression that very few men should attempt this work, because of danger to the patient. There is not opportunity for many men to become expert in this operation. I note that Dr. Horn's examinations were not long continued; this should be remembered as an important factor of safety.

I agree with Dr. Horn in his conclusion as to the error of one author quoted regarding the conditions of the bronchial tubes in asthma. This case occurred in winter; the patient had come from the outside into the warm atmosphere of the hospital and we cannot be so certain as to the influence of the treatment, because, as we know, many cases of asthma are relieved by simply coming into the hospital. I do not think the treatment did any harm and I think it was justified, but I do not think that more than one man in a hundred would be justified in doing bronchoscopy for the relief of asthma. The cocain can be applied more easily and safely through a spray tube passed below the vocal cords or it may be inhaled from an atomizer, with quite as much relief. A method much employed by an irregular who gives patients much relief consists of the inhalation of a small quantity of cocain, atropin and possibly epinephrin—sometimes people are relieved thereby for months; therefore, applications of strong solutions do not seem to me to be justified except in extreme cases, like the one referred to in this paper. The findings of contraction of the bronchus in the fourth examination is interesting. In the other examinations, the large amount of morphin and scopolamin may have prevented contraction. In bronchoscopy, we see rhythmic contraction and relaxation of the bronchial tubes provided the patient has not been overpowered by the anesthetic. In a case which I was demonstrating to a class of doctors, a bronchus from 4 to 6 mm. in diameter, closed so that the opening was not visible. I have seen a bronchus close completely, when search was being made for a foreign body.

I made some experiments about a year ago in the laboratories of the University of Chicago with the view of ascertaining the effects of certain remedies in the spasmodic conditions of the bronchial tubes in asthma. I did not have time to carry these far enough to give me anything worth while, except on one point; in a dog I produced tonic contraction of the bronchus, with almost typical asthmatic breathing, for some time by the insufflation of powdered ipecacuanha. With reference to the position of the bifurcation of the trachea, there is a large chance for error. I have sometimes found it difficult to locate the bifurcation, though I do not think this likely to happen with Dr. Jackson, who is expert and can see better than I. It would not be strange with the variability of the illumination and the anatomic conditions for one to mistake the bifurcation of the main bronchus for the bifurcation of the trachea. I have not examined patients with asthma by this method; I am glad that Dr. Horn has done so and hope it will be done by others, but I hope that not all laryngologists will undertake to cure asthma in this way. It is better to wait until one has had a great deal of experience in bronchoscopy on living dogs, before trying at all. There is all the difference in the world in doing bronchoscopy on the cadaver and on a living subject.

DR. CHEVALIER JACKSON, Pittsburg, Pa.: I am in direct and absolute opposition to Dr. Ingals in only one statement; he stated that I am more expert and can see better than he can; that I deny most strenuously; it absolutely is not true.

My position is about half way between that of Dr. Ingals and Dr. Horn. I do not think every one should examine the bronchi in disease, but that the dangers are very great I do not believe. I do not think that the difficulties are very great in bronchoscopy if it is for therapeutics. Foreign body work is totally different. There it is a problem of mechanics, and good mechanics are born, not made, and lest I be thought boasting, I would state that it is a generally accepted fact that the best mechanics are men of very little brains. I think in the future many men will devote

themselves to the diagnosis and therapeusis of the air passages, using the bronchoscope simply as a speculum, and as a speculum is used in gynecology and other specialties. The field is enormous. We went down into the lower air passages first for the extraction of foreign bodies; then we began to discover pathologic conditions; and we have discovered that there is an immense amount of pathology of the air passages visible bronchoscopically. The time has arrived when diagnosis of thoracic diseases are being made with the bronchoscope. That is the first step beyond the foreign body stage; the next is therapeusis. I regard Dr. Horn's paper as epoch marking in this respect. Now we must bear in mind that an entire year's publication of THE JOURNAL would not contain all the remedies suggested for asthma, which is one of the most complicated of conditions, and it will take a long time to perfect bronchoscopic methods of treatment. When cocaine first came into use we were enthusiastic about curing acute rhinitis and a host of other troubles with applications of cocaine and all physicians know where that drugs stands to-day. I do not think we will apply the bronchoscopic treatment of asthma to all cases, but I think that there are patients who can be cured by local treatment in this way. Asthma is a neurosis and there must be general treatment as well as local; however, this is a step in the right direction and I certainly believe with Dr. Horn that we have here a field for investigation and that patients will be cured in this manner.

I would particularly like to emphasize, however, that we began this work for the extraction of foreign bodies; that we found disease; that diagnosis was the second step, and that the third will be therapeusis.

DR. W. E. CASSELBERRY, Chicago: Even in foreign body work the bronchoscopic examination is of value from a diagnostic standpoint. It might be thought that we would have in the radiograph sufficient evidence of the presence of a foreign body, but it fails to disclose the exact conditions in which the foreign body may exist in the bronchial tract. The point I would make is that we cannot learn what may be vital conditions until we have made a bronchoscopic examination. A case in point is one in which a 1½ inch glass-headed steel pin was plainly enough lodged in the left bronchial tract as shown by the x-ray, but in which on bronchoscopic examination it was found to be immovably transfixed in the first bronchial branch with its head impacted against the upturn of this branch and its point inserted firmly into the bronchial wall. It could be grasped with the bronchoscopic forceps, all suitable kinds being tried, and the force being exerted in all directions, but without success in removing it because of the transfixion until at a second operation it was cut in two. The bronchoscopic pin-cutter which I devised for this case could be used also for needles, safety-pins, etc. To prevent the fragments from flying asunder and getting lost the instrument was so devised that it will hold fast to one of the ends of the pin after cutting. In my case the pin being cut near the point, this end was retained and withdrawn by the cutter and the other end was then picked up with forceps and withdrawn.

DR. HENRY HORN, San Francisco: I have been accused by Dr. Jackson and Dr. Ingals of over-enthusiasm and I desire to plead not guilty. I am not at all enthusiastic about this method of treatment. The paper is simply presented as a pathologic experiment. I selected this case from a number of others that I had been working on, not because of the value of the treatment, but because of this remarkable condition of tonic closure of the main bronchus. As Dr. Ingals truly said, it goes without saying that if one's technic is not good, such work should not be undertaken. Of course, I did not mean that there were no contraindications, naturally there are many, but I mean that before I tried this I would not have done it, for instance, in a case of dilated heart. I only wanted to report this experimental work in the hope that some members of the Section would carry on the idea and see what results could be obtained. Dr. Casselberry said that this patient was brought from the outside into the warm atmosphere of the hospital. As a matter of fact, she had been in the hospital for an entire year, receiving every

treatment that the German Pharmacopeia knows, and she had had morphin every night for a year. It seems to me, therefore, that the result must be credited to bronchoscopy unless it be credited to the mental effect on the patient.

I do not know much about the cocaine proposition referred to by Dr. Casselberry. In a large series of experiments on dysmenorrhea, I was able to relieve the patients by local applications in the nose. I do not know why, but the fact that the pain ceased is true. I simply offer the suggestion that there is some sort of an analogy.

This is not the only case I have worked on. When possible I examined every patient with severe chronic bronchitis who came into the clinic, and almost without exception they said that they were relieved. Why I do not know, but I am of the opinion that the passage of a large instrument into the bronchus is somewhat analogous to the passage of the cold steel sound in the urethra. Before I left San Francisco I had a case in which I did not use morphin or cocaine and the woman, who had severe asthma, had taken stramonium powders every half hour for years. After one passage of the bronchoscope and that only down to the bifurcation she came back two weeks later, without having had to take a powder. So that there must be something in the mere introduction of the bronchoscope.

As regards the position of the bifurcation, perhaps I did not make myself quite clear. I meant the bifurcation of the trachea, which one can hardly miss. One may pass this little opening of the upper bronchus very easily. If you happen to twist the bronchoscope it may be taken for a cicatricial contraction. Dr. Jackson misunderstood me: I said I mistook the constriction for a scar contraction and supposed it to be a result of diphtheria, but it was not as was shown later. Up to the present time there are no cicatricial contractions reported as due to diphtheria.

Now was I justified in making this trial? I think so. If the technic is good, I do not think that there are many contraindications to the procedure. I have had patients tell me that the passage of the bronchoscope is more comfortable than the passage of the soft rubber tube into the esophagus. If the patient doesn't object to the passage of the instrument it cannot be uncomfortable. This work is certainly going to open up a great field in the study of internal medicine as related to the respiratory tract. We are able to recognize many things that a few years ago we never thought of looking for—abscesses, tumors, strictures, etc..

AGAR-AGAR IN THE TREATMENT OF CONSTIPATION IN CHILDHOOD*

JOHN LOVETT MORSE, A.M., M.D.

Assistant Professor of Pediatrics, Harvard Medical School; Associate Visiting Physician at the Children's Hospital and at the Infants' Hospital

BOSTON

Agar-agar is prepared from hot water extracts of various species of *Gelidium* and differs somewhat in its composition according to its origin. It is sold commercially in the form of strips about eighteen inches long, varying in thickness from that of a straw to that of the finger. It contains about 60 per cent. of carbohydrates, principally in the form of galactosan and pentosan.

Saiki¹ did a series of beaker experiments in order to determine its digestibility and obtained negative results, not only with saliva and pancreatic amylase, but also with an intestinal extract containing very active invertin. The digestibility was but little increased by preliminary treatment with dilute acid. He also found that agar-agar was very resistant to the action of the ordinary intestinal bacteria. Only one of three strains of the

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Saiki: Jour. Biol. Chem., 1906, 11, No. 3.

Bacillus coli communis caused gas production in agar-agar media, and that only to a slight degree. Utilization experiments in both animals and man showed that very little (about 10 per cent.) of the polysaccharides was utilized and that the agar-agar was passed through the intestinal canal unchanged.

Agar-agar has the property not only of absorbing water, but also of retaining it in its passage through the intestinal canal. It thus increases the bulk of the feces and prevents the formation of hard, fecal masses. This peculiarity, together with its resistance to bacterial decomposition, suggests its use in the treatment of that form of constipation which is due to complete digestion of the food and to complete absorption of the water from the intestinal tract, the stools being as the result small and very dry. It has been used with good results in the treatment of this class of cases in adults by Mendel,² Schmidt,³ Gompertz⁴ and others. The doses given have varied from $\frac{1}{2}$ to 1 ounce daily. Owing to the nature of its action, no habit is produced and it is not necessary to increase the dose. In fact, it is usually possible to diminish the dose and in some instances to entirely discontinue it. In spite of the fact that agar-agar alters the character of the feces, it does not always induce a spontaneous evacuation of the bowels. This is because it does not exert an irritant action on the intestinal wall as do the products of putrefaction usually formed in the intestine. Schmidt called attention to this fact and added a small quantity of the extract of cascara to the agar-agar in order to supply this chemical irritant. A preparation of this sort is sold under the name of "regulin." This is made with one of the tasteless forms of cascara and is both tasteless and odorless. Whether the tasteless forms of cascara are as active as the others is a moot question. However this may be, a serious objection to this preparation is that it contains two substances having different actions, one acting mechanically by softening the feces, the other as an irritant to the intestinal wall. It is impossible to increase the dose of one without increasing that of the other also. It is much more rational, therefore, if both agar-agar and cascara are indicated, to give them separately, in order to be able to vary the doses of each independently.

Agar-agar is sometimes eaten dry in the stick form, but is more often cut up into small pieces and eaten like a cereal with cream and sugar. It has almost no taste but a rather characteristic gelatinous feel in the mouth. In other instances it is mixed with cereals or cooked in with soups or broths. Schmidt cautions against using it in a too finely divided form, as the rapid swelling from the absorption of moisture in the stomach may cause colic and diarrhea.

I have seen no report of the use of agar-agar in the treatment of constipation in children. Some authors say, indeed, that it should not be given to young children. They do not state, however, why it should not. As there seemed to be no very evident reason why the action of agar-agar should be different in children from that in adults, and as the type of constipation helped by agar-agar is not at all uncommon in childhood, it seemed reasonable to me to try it in spite of these statements. I have, therefore, during the past winter, given it to a number of children suffering from this type of constipation. Their ages varied between $2\frac{1}{2}$ and 8

years. The results have, on the whole, been very satisfactory. It has, in this type of constipation, given much better results than the administration of fruit, vegetables, coarse foods and preparations of bran, or the ingestion of large amounts of water. In many instances it has been possible to stop the use of laxative drugs and in all to diminish their doses. In one instance, however, it seemed to lose its effect after a few weeks. In others it has been possible, after a time, to omit it entirely.

The greatest difficulty encountered has been in inducing the children to take the agar-agar. None of them will take it dry or simply with milk and sugar like a cereal. Some of them will carefully separate out each piece in their mouth and spit it out when it is mixed with cereal. Most of them can be induced to take it in this way if it is cut up into flakes about the size of bran and cooked in with the cereal. It can usually be given to the others in broth or soup, if it is thoroughly cooked before it is mixed in. Several hours' hard boiling are required, however, before it becomes homogeneous enough to mix well; otherwise it will surely be detected by the child.

The dosage is rather indefinite, as the quantities usually given to children are too small to weigh on ordinary scales and hard to measure in spoonfuls because of the comparatively large size of the flakes. Children of 4 or 5 years need, as a rule, about two teaspoonfuls of dry flakes, the size of dry rolled oats, daily. This weighs about one dram. Fortunately no harm can result from either an underdose or an overdose, and after a week or two the amount necessary for the individual child is easily fixed.

CONCLUSIONS

Agar-agar is useful in children, as in adults, in the treatment of the type of constipation associated with small, dry stools. It is harmless and in many instances gives most satisfactory results.

70 Bay State Road.

ABSTRACT OF DISCUSSION

DR. ALFRED FRIEDLANDER, Cincinnati: I have used this mixture of agar-agar and cascara with satisfaction by mixing it with some of the desiccated breakfast foods, or with stewed fruits. In this way there has been no difficulty in administration. Doses of about a teaspoonful to children four or five years old gave a satisfactory result, and no bad habit was ever formed in my experience, even if the dose had to be increased.

DR. C. G. KERLEY, New York: I am sorry that I cannot corroborate Dr. Morse's observation. I have found agar-agar very difficult to give. It answered all right for a time, and then lost its effect. I have given it in over forty cases, and my results were not at all satisfactory. My results at first were about the results we get from most cathartics, and the effect gradually fails. The difficulty in getting a child to take it and the absence of good results did not warrant its continuation.

DR. GODFREY R. PISEK, New York: I have also experimented with agar-agar, and can corroborate what has been said about the difficulty of administration. With oat-meal it was taken better than in any other cereal, but the difficulty in getting the child to take it was a great disadvantage. There are a number of selected cases in which I believe agar-agar is beneficial, that is, in those in which there is a deficiency in the amount of the feces and those that have had all manner of drug treatment. These patients react because of the bulk which is left in the intestine, although one is sometimes obliged to stimulate the discharge of the feces by a suppository. At the same time, the fecal movement is softer and larger than ever before, and the parents are satisfied that

4. Gompertz: Am. Jour. of Med. Sc., October, 1909.

progress has been made toward relieving the obstinate constipation. This is so in a limited number of cases, however. I have lately also tried beet-root, but am not as yet prepared to give a report on these cases.

Dr. J. L. Morse, Boston: I am sorry that Dr. Kerley has had so much trouble with agar-agar, and I wish he would try it again. I want to repeat that agar-agar is not a drug, at least, I do not consider it a drug. It is merely a method of keeping the feces moist and increasing their amount. It does not have any irritant action on the intestine.

THE PRACTICAL USES OF ELECTRICITY IN MEDICINE *

CHARLES S. POTTS, M.D.,
PHILADELPHIA

While it is true that electricity is an agent of much practical therapeutic value, it is also true that it is looked on with skepticism by a large number of the profession. The reasons for this would seem to be two-fold: First, the great majority of those who employ it do so without a proper understanding of its capabilities, limitations and the proper technic, and hence do not get the results they expect. As an example of this I not long ago saw a patient with paralysis of the arms due to a neuritis induced by lead, to which the faradic current had been ordered applied for twenty minutes twice daily by a prominent physician. The uselessness and possible harmfulness of such a procedure will be apparent to all acquainted with the proper use of electricity. In hospitals also the electricity is frequently applied by a nurse, who, as a rule, has received no intelligent instruction in its use. Second, some of those who have made a special study of it, have in their enthusiasm made such extravagant claims on slight evidence that many have come to look on all claims made for it either with distrust, or attribute any beneficial results to its psychic influence alone.

THE DIFFERENT CURRENTS AND THEIR PHYSIOLOGIC ACTION

The passage of the electric current through the body does produce actual changes in functions and tissues and for it to be used at all intelligently some knowledge of these varied physiologic actions is essential. These differ somewhat in degree according to the form of current used. There are now employed therapeutically the galvanic or constant, the faradic or induced, the sinusoidal, static and high frequency currents. X-rays while due to electricity, and the various forms of light which may be produced by it, are not considered here.

THE CONSTANT CURRENT

The constant current possesses all of these actions to a greater degree than any of the rest. In the other forms of current some are either absent or so slight as to be practically disregarded in considering the indications for their use. The therapeutic activity of the constant current depends principally on its so-called polar effects, which occur at each pole, the interpolar effects occurring in the region between the poles, and its power of producing muscular contractions. The first consist of electrolysis, phoresis and electrotonus. By its electrolytic action the tissues of the body, composed principally of salines in watery solution, in the region of the poles are

decomposed into their ultimate elements or ions, with the result that the anions, oxygen, chlorine and acids appear at the positive pole or anode and the cations, hydrogen, alkalis and bases are found at the negative pole or cathode. If the current be sufficiently concentrated, caustic and destructive effects are characteristic at each pole, the positive pole particularly searing the tissues by the acid generated, and thus stopping hemorrhage.

By phoresis the fluids and solids either in solution or small particles produced by the electrolytic action just mentioned are transferred from one pole to another, the bulk of the fluids, hydrogen, alkalis and bases (cations) going from the positive to the negative pole and a lesser amount of fluid with oxygen and acids (anions) passing from the negative to the positive. There is thus a double current passing between the two poles. The former is known as cataphoresis and may be employed in therapeutics for the introduction of various drugs into the body; the second is known as anaphoresis and under some conditions, as when it is desired to introduce an acid, may be employed as cataphoresis is. In addition, osmosis is increased, fluids being driven from the anode to the cathode. By this property also we have an accumulation of fluid at the negative pole and consequent vascular congestion, while at the positive pole there is depletion. If the current is weak, these changes are not noticeable, but they are occurring. The electrotonic effects consist of the production of catelectrotonus, or an increased excitability of muscle and nerve produced by the negative pole or cathode, and anelectrotonus, or diminished excitability of muscle and nerve, produced by the positive pole or anode. Muscular contractions are only produced when there is a sudden increase or decrease of the current density, in other words when the circuit is either suddenly opened or closed. While the various phenomena just mentioned are observed most markedly at the respective poles, electrolytic and phoretic effects also take place in the region between the poles. As has been previously stated, whenever the current passes through an electrolyte electrolysis occurs and when it does occur the ions of the decomposed molecules are transferred from one pole to the other according as they are anions or cations. The constant interchange produces metabolic and vascular changes, which facilitate the absorption of morbid exudates and adhesions. To a certain extent also the galvanic current possesses bactericidal properties, but as it is only with very strong currents, it cannot be employed practically for this purpose. It may be said, therefore, that the positive pole is sedative to nerve and muscle, hence may relieve pain and spasm; is capable of diffusing drugs through the skin (cataphoresis, anodal diffusion), is depleting and hemostatic. The negative pole is stimulating to nerve and muscle, hence improves their nutrition, increases moisture and congestion, and if strong concentrated currents are used is most destructive to tissue.

THE FARADIC CURRENT

The faradic or induced current has no power to produce the polar and interpolar effects possessed by the galvanic current, but is an efficient agent in causing muscular contractions, except when the lesion is in the peripheral neuron; i. e., peripheral nerves, nuclei of the cranial nerves and cells in the anterior horns of the gray matter of the cord. It also, when rapidly interrupted, acts as a sedative to sensory nerves and thus may relieve pain. In this respect it is believed to be more effective if a fine wire coil is used. If used with a dry

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

fine-point electrode as the metallic brush, so that the current is at high tension, it stimulates the sensory nerve-endings and may be of value in some forms of anesthesia and paresthesia. As it produces contraction of the muscles it may, if a number of them are excited, cause changes in general nutrition. Weir Mitchell found that an elevation of the body temperature resulted from such use.

THE SINUSOIDAL CURRENT

The sinusoidal current is an alternating current obtained from a rotary converter or dynamo. It differs from the faradic current in that the alternations are gradual, those of the faradic being abrupt. Hence it is much less painful. It differs also from the faradic current in that it will cause muscular contractions in muscles cut off from their trophic centers (peripheral neuron lesions), and is said to be especially effective in exciting contractions of involuntary muscle. Otherwise it acts similarly to the faradic current.

THE STATIC CURRENT

The static current is unidirectional, and hence has a positive and negative pole which have different actions, the positive being sedative and the negative irritating, similarly to the galvanic current. It acts either locally or generally according to the technic employed. Sparks cause contraction of the muscles and other tissues and hence may relieve local congestion or stasis by squeezing out the fluid contents of the tissues and forcing them in the direction of the lymphatic and blood streams respectively. They thus may relieve pain and remove exudation. After the initial contraction there is dilatation of the small vessels and hyperemia. The positive spark is less painful than the negative. Similar results may be obtained by the so-called static wave current.

The spray or breeze especially if positive with negative insulation, is soothing and may relieve pain. The brush discharge, by which is meant the discharge taking place between a patient insulated and connected with a static machine and an electrode of some resisting material as wood, causes considerable local hyperemia, hence an increased leucocytosis, and has been found useful in conditions similar to those in which Bier's hyperemic treatment is indicated. The static bath is asserted to cause metabolic effects shown by increased frequency of the pulse, which may persist for some time after the treatment; a slight rise in temperature, an increase in respiratory combustion; when used with positive insulation an increase, and with negative insulation, a lowering, of the blood pressure; a tendency toward drowsiness; an increased excretion of urea and some increase in the gastro-intestinal functions.

HIGH-FREQUENCY CURRENTS

High-frequency currents also produce a local and general action. The former is produced by either the spark or effluve, and the effect is somewhat similar to that caused by the static spark, except that the contractile action is not so great. Hyperemia with increased leucocytosis and consequent phagocytic action is caused, and some believe that owing to the absorption of the ozone produced there is an increased germicidal action in the blood. There is also, owing to the capillary dilatation, more or less fall of blood pressure. A temporary lessening of the sensibility of the sensory nerve-endings also occurs. Ultraviolet rays are produced. Concentrated sparks are destructive to skin and

small morbid growths. Static sparks also act in a similar way. Local influences are best obtained from either a Tesla coil or resonator, both of which produce currents of high voltage and small amperage.

Freund has asserted that the irritation of the skin and peripheral nerve-endings by these and other forms of high-tension discharge (static spark or the spark from a Rhumkorff coil) reflexly influences distant internal organs. This observation has some significance when the studies of Head¹ are considered. He showed that disease of the viscera caused certain definite areas of pain and tenderness in the skin, there being a constant relationship between the organ affected and the locality of pain and tenderness, this being due to the connection between the sympathetic supply of the viscera by means of the white rami communicantes with the spinal cords and nerves. Brief applications of either static or high-frequency sparks may cause some elevation of blood pressure. Muscular contractions similar to those caused by the faradic or sinusoidal currents are produced by currents from either the D'Arsonval or primary Tesla coils. General influences are better obtained from the D'Arsonval current, which is of lower voltage and greater amperage than either the Tesla or resonator currents. Marked changes in metabolism are produced by it. These are increased tissue changes, more rapid oxidation and increased elimination of waste products in the urine, and, according to most observers, marked diminution of blood-pressure.

EFFECTS ON BRAIN AND CORD

In addition to these various actual changes which electricity is capable of causing in the tissues of the body, must be added its action on the higher mental functions in producing mental impression or suggestion; in other words, its psychic influence. A question of some importance is whether electricity can influence directly the brain and cord through the tissues that cover them. The galvanic or constant current is the only one which seems to have any effect whatever on these structures. Erb showed that galvanization of the head, the electrodes being placed either on each temple or mastoid process, causes vertigo and flashes of light from stimulation of the optic nerves; it seems doubtful, however, that if a current of a safe strength is used enough will reach it after passing through the various coverings of the brain to be of any therapeutic value. Many believe that it will, but I know of no instance where muscular contractions have been produced by such means, and any one who has ever stimulated the exposed cortex, knows how weak a current is used to produce them. Brenner (quoted by Erb) interrupted the galvanic current that was being passed transversely through the head without producing any.² The spinal cord is still more protected by exceedingly thick muscles, ligaments, and membranes and a still greater diffusion of current would occur than in the case of the brain. Erb believed that it could be stimulated, and gives as proof the fact that he placed two electrodes over the vertebra, one being over those of the upper lumbar region, and caused contraction in the muscles supplied by the sciatic nerves. This, however, if the current was strong, could be produced by the diffusion of the current through the mus-

1. Head: Brain, xvi, 1, xvii, 23.

2. Le Duc has undoubtedly influenced the brain by an interrupted galvanic current. The so-called electric sleep or anesthesia being produced. Dangerous symptoms have also been caused and so far it seems to have no practical value.

cles of the buttocks acting on the nerves. If it was caused by the current entering the spinal canal why were the sciatics alone affected?

THERAPEUTIC USES

As indicated by the title, the scope of this paper includes only the uses of electricity in medicine, but it may be said in passing that it is of use in a number of surgical affections; for instance, the employment of either the electrolytic properties of the constant current or the destructive action of static and high-frequency sparks for the destruction of small growths, nevi, moles, etc.; the production of hyperemia by either high frequency or static currents in the treatment of sprains and other local inflammation, and this property combined with the action of the actinic rays generated and the ozone liberated as a remedy for various ulcerations and infections of the skin.

NERVOUS DISEASES

The agent was originally employed medically in the treatment of diseases of the nervous system and there can be no doubt as to its value, when properly used, in the treatment of motor paralysis due to any cause. By this I mean when employed as a means of producing muscular contractions. Whether, as has been before mentioned, enough of the current can be made to reach either the brain or spinal cord to either improve their nutrition or remove sclerotic tissue is an open question. I have never seen any beneficial results from its use in this way. At the same time it must be remembered that the muscular contractions caused by it react on the nerve centers and improve their nutrition, this being especially so in conditions where there is commencing degeneration of spinal or cranial nuclear cells, as in anterior poliomyelitis, etc.

Electricity has been used in various ways in the treatment of tabes dorsalis. That it may at times relieve many of its symptoms, such as the various forms of paresthesia and pain, there is no doubt, but it is difficult to see how it can remedy the disease itself for the reason that even if the attempts to reach the cord were successful the remedy would be useless, because the disease process probably starts in the meninges and posterior nerve roots; therefore involvement of the cord is due to a secondary degeneration produced by cutting off nerve fibers from their trophic centers. As the nerve fibers of the cord, once destroyed, cannot be regenerated, when the disease has reached there irreparable damage has been done. The sedative action of the galvanic anode may at times relieve local muscular spasm; this at times may be of service in the treatment of the contractures resulting from cerebral apoplexy, especially if the weaker extensors are strengthened with the faradic current. This anodal action is also often of use for the relief of the pain of acute neuritis and symptomatic neuralgias. It may be of service in chronic neuritis, especially sciatica, but in such cases better results are usually obtained from either the static or high-frequency currents employed to produce their local hyperemic and contractile action. Most satisfactory results can be obtained in such cases by the proper use of these currents.

The good results that may be obtained in hysteria are well known, such results being due both to the power of causing mental impression and also, possibly, in some instances, the general tonic action of the current.

Electricity may also be of service in neurasthenia. The headaches and other aches and pains are certainly

helped by the static spray. More vigorous treatment may also aid in arousing dormant energy and increasing blood pressure. In some cases good results may be obtained from employing either high frequency or static currents to obtain their general metabolic influence. There can be no gainsaying the favorable influence of general faradization as a part of the rest treatment.

Sexual weakness and psychoses are certainly benefited by electrical treatment.

In the occupation neuroses I have tried various forms of electricity without much satisfaction. Some, however, have claimed good results. As many of these cases are neurasthenic it may be of service with other measures, as a general tonic.

The use of electricity in epilepsy has been advised by some. From the very nature of the disease, however, it is difficult to see how it can be of service. Those who have had large experience in the treatment of the disease have nothing good to say for it. Many cases of so-called epilepsy, also, will be found, if carefully studied, to be due to various organic causes that electricity cannot influence. As autointoxication has some influence in exciting the paroxysms, the asserted eliminative action of high-frequency currents may prove of benefit in some few cases.

The same may be said for its use in chorea, which, if of the ordinary Sydenham's variety, is probably due to an infection, and if of the hereditary type is due to organic changes of the brain-cells and fibers that could not be influenced by electricity. The importance of not using this agent in a haphazard way is shown by its possible employment in myasthenia gravis, a disease in which there is marked exhaustion of the muscles following exertion. One ignorant of the symptomology and history of this disease might be tempted to employ electricity as a muscle tonic when the very exciting of muscular contractions by this means would aggravate the condition.

In mental diseases electricity is of use only in stuporous conditions. In these benefit may sometimes be derived from the application of static sparks as a means of arousing the patient.

ARTHRITIS AND MYALGIA

Since the development of high-frequency currents the range of usefulness of electric treatment has much increased. One of the most valuable has been in the treatment of diseased joints. This is probably due to their power of producing hyperemia. The joints in rheumatoid arthritis especially may be much benefited by their use. In conditions of partial ankylosis following arthritis the absorption and removal of the morbid tissue may be often hastened by utilizing the electrolytic and cataphoric properties of the galvanic current.

Lumbago and manifestations elsewhere of so-called muscular rheumatism may be often quickly relieved by the proper use of electricity.

VISCERAL DISEASES

Williams³ and others have advocated high-frequency currents in the treatment of tuberculosis of the lungs and have claimed excellent results. It can do no harm, but if used other recognized and more commonly used methods of treatment should be employed in conjunction. In diseases of the stomach the use of the current has been advised by Ewald, Einhorn, D. D. Stewart and others. It is most applicable in conditions where there

VISCERAL DISEASES

Williams³ and others have advocated high-frequency currents in the treatment of tuberculosis of the lungs and have claimed excellent results. It can do no harm, but if used other recognized and more commonly used methods of treatment should be employed in conjunction. In diseases of the stomach the use of the current has been advised by Ewald, Einhorn, D. D. Stewart and others. It is most applicable in conditions where there

3. Williams: High Frequency Currents, p. 166.

is either atony, dilatation or functional pain. In chronic constipation from intestinal atony excellent results are obtained.

The lowering of arterial tension by high-frequency currents, especially the D'Arsonval, has been previously mentioned. It has been used for this purpose by many, but that it possesses any advantages over other methods of treatment I am unable to say. The eliminative properties have also been used in chronic nephritis with asserted success and in conjunction with other measures it may be of some help.

The value of the coagulating power of the galvanic anode in the treatment of sacculated aneurism is well known. Hunner⁴ of Johns Hopkins University collected reports of 23 cases, in which there were 4 cures and 9 patients were markedly improved. Other successful cases have been reported since.

The frequency of the heart in exophthalmic goiter may also at times be lessened by the employment of the galvanic current.

Electricity has been found useful in many diseases of the eye. As this, however, is a subject of special interest and not within the domain of general medicine, I will do no more than mention it. The same may be said of diseases of the skin. In addition it may be said that the development of high-frequency currents has greatly increased the value of electrical treatment of many of these diseases.

GENITOURINARY AND PELVIC DISEASES

Electrolysis has been employed in the treatment of urethral stricture by a number of different methods. While successful in some cases, the method has not found favor with genitourinary surgeons. Electricity has also been employed in various ways in the treatment of prostatic hypertrophy, but has not met with much favor. More can be said of its use, especially currents of high frequency, in chronic prostatitis. Disorders of the genitalia of women of a medical nature, as distinguished from those purely surgical, may be benefited by the proper use of electricity. B. C. Hirst advises the use of the galvanic current in amenorrhea, in menorrhagia, especially when due to fibroid tumors, and in hypoplasia of the uterus, and the faradic current for weakness of the vesical and rectal sphincters. It has also been employed in other conditions of these organs of a more distinctly surgical nature with asserted success. As a rule, however, in such cases surgical methods will be found preferable.

Of no small therapeutic value is the property of cataphoresis by which drugs can be introduced into joints and certain cavities of the body.

CONCLUSION

In the space allotted it has been possible to give but a very general mention of the capabilities of this agent. It has been of value in many surgical conditions not properly considered in this paper. It has also been employed in diseases within the domain of internal medicine which have not been mentioned here, as there seems to be no good reason for their treatment by electricity. In conclusion I repeat that to get results from the use of this agent it should be used conservatively, with proper understanding of its physiologic action and of the proper technic.

1728 Chestnut Street.

ABSTRACT OF DISCUSSION

DR. G. BELTON MASSEY, Philadelphia: This interesting paper is an up-to-date statement of the value of electricity in many medical affections; but it indicates one of the errors of my colleagues in presenting electrotherapeutic subjects in too general a way. While we have here an enormous range very well stated of electrotherapeutics in this late day, I think we learn more from a discussion of more circumscribed subjects, with the technic equally well stated but with some portion of the statement in the shape of detailed cases; for after all, our work as physicians is the relief of individual patients. Only last night I was asked to see in consultation in this city a patient in whose case the value of electricity in a hemiplegia case was involved. I knew of nothing to lead me to say that it would be of any value. The academic statements proving the transmission of the current are familiar to us, it having been proved that a minute current will go through the brain after having traversed the living skull structures; but it has also been proved that the bulk of the current will go round the scalp structure. So that in practical medicine we do not need to waste much time on some of these questions of that nature. We want to get down to the actual clinical facts.

It is a mistake to regard electrotherapy as a new subject. I was only recently on the other side at the Physiotherapeutic Congress in Paris, and the scientific exhibit in the hall of the Sorbonne showed ancient apparatus designed by medical leaders for most of our uses of electricity. It is nothing new. The new thing is to bring down to the concrete what we can do for the individual patient by this form of force.

Speaking of hysteria, I fancy the usual feeling about the treatment of this affection is that we must put the patient to bed and carry him through an expensive rest-cure treatment. That is of very great value in the hands of experts, but the ordinary practitioner can often do better than to employ the rest-cure, static electricity being of extreme value in this state. Moreover, it enables us to differentiate between hysteria and neurasthenia, which is a very important matter, particularly if the rest-cure is contemplated, for I think the rest-cure is generally harmful in neurasthenic patients. This test is based upon the fact that static sparks are most painful to neurasthenic patients, and possibly harmful too, while but little pain is produced by them in hysteria. The differential value is in that a large number of hysterical patients show more or less anesthesia. In other words, the static spark is wonderfully well borne by the hysterical patient. Moreover, the patient feels better immediately after the application of the static spark. So that with this method of treatment such patients may be kept on their feet and have the benefit of exercise and other judicious agents. Speaking of the prostate, Dr. Potts made an excellent distinction there. We have a true fibroid tumor of the prostate of the slowly developing form and greatly interfering with the functions of the bladder, and in these cases electricity is not quickly valuable. But the static spark even in these cases will give great relief, removing congestion, relieving the prostatitis and often practically curing the patient; and that is to be expected in cases of pure prostatitis or chronic enlargement of the prostate. I am a little amused that Dr. Hirst, a very recent advocate of electricity in fibroids, is quoted by Dr. Potts as an authority on the subject. It is very pleasing, however, that Dr. Hirst accedes to that sixteen-year old propaganda as to the value of electricity in many gynecologic conditions, particularly in fibroid tumors of the uterus. There seems to me a peculiar value attaching to electric modalities in gynecology, partly due to the fact that we use here very large, commanding currents, currents capable of doing work because of their lack of pain. The field in gynecology is enormous.

DR. DAVID PAULSON, Hinsdale, Ill.: I want to speak of the value of the slow sinusoidal current in relaxed conditions of the abdominal wall. With the sinusoidal current it is possible to produce the most vigorous contraction of the abdominal muscles as well as contractions of the internal ligaments, by simply placing two large electrodes on each side of the abdomen. If persisted in day after day these temporary ef-

⁴ Bull. Johns Hopkins Hosp., November, 1900.

fects ultimately become more or less permanent. It is possible to make a very strong application of the sinusoidal current without producing any pain; hence its great value in these cases.

DR. ALFRED T. LIVINGSTON, Jamestown, N. Y.: It has been implied that the electric modality called galvanism is not particularly efficacious or at least has not many appropriate applications. As to the effect on the brain secured by passing the current through the skull, I think Dr. Massey has made a correct statement; but that is not the way to influence the brain. The brain condition is influenced by stimulating the vasomotor centers which control the circulation in the brain; and that can be done without any question by the application with sponge tip electrodes or some other form, over those three chief centers, the upper, middle, and lower cervical sympathetic ganglia. I have always observed that the stimulation of the lower pair has the most marked effect on the circulation in the head. I recall one of the most extreme cases of acute mania in a woman in Philadelphia, who was brought to my house at about 8 p. m. It seemed from her state that there was not much likelihood of securing sleep, but I took my galvanic battery to her bedside and solely by the use of the galvanic current I put that woman to sleep within three-quarters of an hour by stimulating the cervical sympathetics. I have also used it in cases of hysteria, hysteric convulsions. Dr. Massey referred to the use of the static spark in hysteria. If I were to be limited to but one form of electricity, I would certainly select the oldest of all—galvanism—as having a wider range of application and more certainty of effect than any other. I have also used a hypodermic injection of ergot and within fifteen minutes I have quieted as excited a hysteric patient as I have ever seen. I am perfectly satisfied that the effect of the galvanic current is exactly the same, producing vascular contraction where there had been dilatation. I have used the galvanic current in cases of blindness of various sorts, particularly in cases of atrophy of the optic nerve, and restored a very good vision which continued through many years. Patients whom I treated twelve or fifteen years ago are going about the streets to-day like other people, attending to their business although their cases had been pronounced absolutely hopeless by ophthalmologists, and I was ridiculed for thinking of bettering their condition. I apply the positive pole at the back of the neck with an electrode of 4 by 6 inches. The negative is applied by means of clay electrodes, pulverized clay moistened by water to a paste condition and laid only on the closed lids, the face except the lids being protected by a piece of rubber dam having holes corresponding to the orbits. A pliable metallic electrode such as tin foil is laid over the clay and connected with the negative pole. In this way I have given 15 milliamperes for two and a half hours.

DR. H. M. WHEPLEY, St. Louis: I regret that the author of this paper is not present to explain the purpose for which he wrote it. Previous speakers have criticized the paper as being one which has not given specific cases or detailed technique. I believe that the purpose of the author is to show that caution must be exercised in the proper use of electricity. He points out the variety of forms in which it can be used but avoids going into the citation of detailed cases, which causes so many of the medical profession to rush headlong into the use of electricity without understanding when, where, or how to use it. This paper is filled from beginning to end with the suggestions of caution in the use of electricity. I recall the frequent use of such phrases as "some believe," "Dr. — has claimed," "it is stated," "it may have benefited," "it seems doubtful," etc. This paper is a warning to the medical profession to study electricity carefully in a general way before giving too much attention to reports of specific cases. The use of electricity in medicine is nothing new, but this paper indicates that it is often used carelessly. Its use by the laity is along very empirical lines; I believe that a paper of this kind full of cautions and written for publication in the newspapers would have a wonderfully good effect on the public. We know only too well how ready the public is to use electricity as a medical agent; laymen buy

so-called batteries and other forms of apparatus claimed to produce electricity when there is no possibility of its being generated by the apparatus that is sold for that purpose. I feel that the paper from the standpoint of the author is not subject to criticism that has been made of it by the previous speaker. It does not go into the details of cases and technique, but it does sound a timely note of warning to those who use electricity in a haphazard manner.

DR. HAVEN EMERSON, New York: If a quarter of what is so conservatively claimed by Dr. Potts' paper is correct, certainly the medical schools of the country ought to take on themselves the burden of teaching some of the elementary principles of electrical application in the treatment of disease. If anybody has seen the relief from lumbago and sciatica, if anyone has seen the improvement in chronic joint affections which electricity will give, I think he will admit that electricity deserves as much consideration in the courses of medical instruction as a good many of the drugs which are now admitted as valueless in the treatment of disease. The teaching of intelligent pharmacology has eliminated a good many drugs from our class rooms. The inclusion of some such methods as Bier's hyperemia and electricity in the teaching of applied therapeutics will certainly help us in diffusing a knowledge of appropriate treatment. I am of the opinion that electricity assists in restoring the tissues to normal, after chronic inflammation, by improving local circulation, by developing hyperemia, and that in exact experimental analysis of the results we should find that this is the cause of its benefits. Massage, constriction, hyperemia, and electrotherapeutics deal with the local blood-supply. Such measures are as useful as many a drug taught and prepared in pharmacologic studies, and their consideration should be included in our medical schools.

DR. G. BERTON MASSEY, Philadelphia: I appreciate Dr. Whelpley's skill in extracting from this paper what suited him, but I must object to his failure to remember that I spoke very highly also of Dr. Potts' paper. I must protest that we are not here for newspaper articles. We are here to advance each other's art of treatment, and mere negations will not help us.

CLIMATIC TREATMENT OF PELLAGRA

A PRELIMINARY NOTE

C. C. BASS, M.D.
NEW ORLEANS

All writers on pellagra seem to agree that it is a disease of warm countries and of the warm season; that patients with the disease usually improve at once when cold weather sets in, and that many of them never show further evidence of the disease. The literature at my disposal does not show that cold climates have been tried for the treatment of the disease, owing largely, no doubt, to the fact that many pellagra patients cannot afford the expense of going to and of living in such climates. In a paper published in 1909 I called attention to the probable influence of temperature on the course of pellagra.¹

On several occasions in discussions on the subject last year, notably at the pellagra conference in Columbia, South Carolina, in the symposium on pellagra of the Southern Medical Association, and at the conference on pellagra at Gulfport, Mississippi, I also called attention to this fact and proposed the advisability of arranging artificially refrigerated wards, especially for the poorer class of pellagra patients who could not take advantage of climate.

In June, 1909, I had arranged, with very limited means at command for the purpose, an artificially refrigerated room for a pellagra patient then under treatment.

¹ 1. New Orleans Med. and Surg. Jour., August, 1909.

This was a mechanical failure, as it reduced the temperature only about 12 degrees, which was very little below the summer temperature.

I had the fortune to see in the spring of 1910 a patient with pellagra who had gone to Colorado for similar symptoms in 1909. She was then greatly relieved by the climate, according to her statement, and remained well; but the same influences of diet and hot weather induced another attack. She returned to the mountains of Colorado and was promptly relieved of all recognizable symptoms.

Since that time I have sent to Colorado four other patients, all of whom are symptomatically relieved. They have all gone to Denver and after spending a few days there to become accustomed to the altitude, three of them have gone higher up in the mountains. One of them was bed-ridden when she left here but was up in ten days and without recognizable symptoms of pellagra in two weeks.

I have sent two patients to Monteagle, Tennessee, and they write that within one week they had improved wonderfully and almost all symptoms had disappeared.

These cases and others will be reported more in detail when the results obtained can be more definitely stated. This preliminary note is published now in order to suggest the treatment for the benefit of the August and September crop of cases.

741 Carondelet Street.

PARSIMONY IN NUTRITION

GEORGE M. NILES, M.D.

Professor of Physiology, Southern College of Pharmacy; Associate Professor of Physiology and Dietetics, Atlanta School of Medicine; Gastroenterologist to the Tabernacle Infirmary

ATLANTA, GA.

This title, adapted from a recent address of Sir James Crichton-Browne, represents a wide-spread dietetic movement which I view with some concern. Previous to this century, throughout the history of the advancing civilizations of the earth, there has never been any concerted effort toward parsimony in nutrition; and, with the exception of certain ascetic orders, whose habits of self-denial were either religious or esthetic, the desires for food have been universally gratified, subject only to limitations of purse or environment. The doctrine that a strong body should be generously fed, and that a virile people should be hearty eaters, was of world-wide acceptance. Furthermore, it was noted that the liberal consumers of the flesh proteins figured most largely in the arts of both peace and war, while the vegetarian nations either lagged behind, or were the servitors of their meat-eating masters.

In accordance with these historic and economic facts certain dietetic standards have been fixed, these standards being the aggregate result of statistical and experimental studies carried out by many physiologists on numerous large groups of individuals under varying circumstances. These results were collected by Atwater, of this country, and Voit, of Munich, who found that an average individual under average conditions thrrove on a daily allowance of 118 gm. of protein food, 56 gm. of fat, and 500 gm. of carbohydrates, such as sugar and starch, this containing 3,055 large calories, or heat units. Under increased physical exercise this was raised to 3,370 calories. These findings were approxi-

mated by a large number of independent observers, most of them, however, allowing a slightly higher daily protein ration.

These standards having been settled with supposed immutability, all was serene until in the dietetic firmament there appeared a new galaxy. We were informed that the theories drawn from the dietetic experience of untold millions of progressive and militant human beings, were altogether erroneous; and, like the man with the eight-day clock, who wound it up every night for twenty-five years before he discovered his error, we have been partaking of double or treble the amount of protein necessary for our well-being. We might say that after these cons the light has just broken in, opening up to us a new heaven and a new earth.

The advance guard of this new thought was Mr. Horace Fletcher, a gentleman of intelligence and culture, who, finding himself obese, dyspeptic, and in declining health, accidentally discovered that by slow, deliberate eating he was much benefited. Being both observant and analytical, he reasoned out a theory that the whole process of bodily nutrition is materially affected by the preliminary treatment of food in the mouth; furthermore he became satisfied that by most thorough mastication and insalivation less food is required for adequate nutrition, while bodily conditions are improved. He sums up his philosophy as follows: "If you eat only when you have an earned appetite, masticate your food thoroughly, and take great care to eat only what your appetite approves, the rest will take care of itself."

Like many other fads containing elements of truth this "chewing fad" attracted to it a circle of adherents, and, fortunately for Mr. Fletcher, it caught the ear of some level-headed physiologists, among others the late Sir Michael Foster, of Cambridge, England, and Dr. Van Someren, of Venice, the latter of whom read a paper on "Fletcherism" before the Congress of Physiologists at Turin in 1901. This led to a series of experiments at Cambridge, which were later continued in America by Professor Chittenden, of Yale, the latter, however, losing sight of the chewing feature, except as it lessened the craving for food, and hinging his experiments on the momentous question: What is the proper daily protein ration best to meet the requirements of the average human body?

The investigations of Professor Chittenden,¹ are in some respects epoch-making contributions to physiology. The experiments were on groups of professional men, army volunteers, athletes and animals, and proved to his entire satisfaction that 60 gm. of protein daily is sufficient for a man weighing 154 pounds, or practically one-half of the previously accepted standard. To quote his words:

These are perfectly trustworthy figures, with a reasonable margin of safety, and carrying perfect assurance of really being more than sufficient to meet the true wants of the body, adequate to supply all physiological demands for reserve protein, and able to cope with the erratic requirements of personal idiosyncrasies.

The limits of this paper will not permit an analysis of Professor Chittenden's experiments, showing where fallacies may exist, or where conclusions are drawn on too meager evidence. He is a doughty antagonist, and one may well hesitate before breaking lances with either him or the formerly obese Mr. Fletcher. They have

1. Chittenden: *Physiological Economy in Nutrition*; and *The Nutrition of Man*.

made out a strong case, but not an impregnable one, and I humbly suggest that we pause and consider before revising our whole dietetic system, not simply, as expressed by the recent tariff tinkers in Congress, "revising it downward," but absolutely cutting it down to half.

That a large percentage of the American people eat too much is admitted; that a large percentage, especially the well-to-do, ingest a surplus almost from the cradle to the grave cannot be gainsaid. The great number of middle-aged and old people, who constantly throng the doctors' offices and health resorts, seeking help for overtaxed eliminative organs, mournfully attest to past gastronomic excesses; but that the American people, as a nation, consume too much protein food, or that our national virility is handicapped by gluttony, cannot be conceded by any student of present-day history.

Leaving for a time the discussion of this subject in its larger aspects, a common illustration of parsimony in nutrition is the custom of some medical men of putting patients on dietaries without duly considering the caloric values contained therein. It would be thought careless indeed should the physician, not know, in prescribing atropin or strychnin, how much in the aggregate was being taken daily; yet it is just as irrational to expect an invalid to gain strength on a diet furnishing insufficient calories, as to expect physiologic effects from inadequate doses of drugs.

I have several times seen persons unwittingly starved to a dangerous degree, and in one instance a case came under observation in which the patient, while being treated for an acute disease, was really starved beyond the power of recuperation before his true condition was recognized.

The appetite of healthy individuals or large groups of men will generally prove a reliable index to bodily needs, but in digestive disorders accompanied by malnutrition it is not enough for the physician to cut out offending articles of food; he should also see to it that sufficient calories are being furnished. Right here it is proper to sound a note of warning concerning the alcoholic proprietary foods on the market. As an auxillary to other nourishment they have their place, and are not without value, but to give them in amounts large enough to meet ordinary caloric needs would result in continued alcoholic intoxication.

A few years ago in New York City I saw a genuine attack of delirium tremens complicate a case of typhoid fever, in which for two weeks the patient had been generously "supported" by a well-known and popular proprietary food. In this connection I wish to commend the thorough and impartial work of the Council on Pharmacy and Chemistry of the American Medical Association, whose very lucid reports have done much to dispel the glamour thrown about some of these alcoholic "supportives" and individually I desire to speed it in its meritorious labors.

The dry proprietary foods are equally unsatisfactory, because in adequate quantities they often disturb digestion more than the ordinary wholesome foods, while the caloric value claimed for them is unreasonable. Dr. David Edsall, of Philadelphia, recently weighed a specimen of one of these dry foods, and reported that if all its weight were nutritive material (a liberal estimate), it was so light that it would take \$1.25 to \$1.50 to buy an amount equal in food value to a five-cent loaf of bread.

Some of the most graphic examples of parsimony in nutrition are exhibited by infants (not the chubby ones with roly-poly little bodies extolling the virtues of various brands) whose eager digestive organs are vainly attempting to glean sustenance from some of the infant foods on the market.

Dr. John Howland, of New York, in a late paper on proprietary and predigested foods, showed by calculation that two of the most representative and widely used of these foods have little more than twice the nutritive value of whole milk, and that without the alcohol they contain the same nourishment as milk. The dose of these foods advised for a child of six months is a teaspoonful every four hours, which would give the infant the munificent equivalent of two ounces of milk daily! Dr. Howland further says:

Assuming that such a food could be ingested without grave gastric, intestinal or other disturbance in sufficient quantity to nourish the six-months-old infant, it would cost about a dollar a day, and would, moreover, require the child to take in twenty-four hours alcohol equivalent to six ounces of brandy, enough to terminate his short life or keep him in a continuous state of alcoholic coma.

Another greatly overrated class of foods leading to parsimony in nutrition are the meat-juices (not meat extracts), for which fabulous powers have been claimed. Well-expressed juice obtained from freshly chopped beef may contain a fair amount of actual nourishment in the form of coagulable proteins and meat bases, and is useful to tide over emergencies, or to satisfy the patient that he is being fed. It would take the stomach of a rhinoceros, however, to hold up under a continuous diet of meat juice for any length of time.

As to meat extracts, they are beyond parsimony—they are a delusion and a snare. To quote Dr. A. L. Benedict, of Buffalo.

A meat broth prepared at a temperature above 160° F., the coagulation point of albumin, contains salts, extractives, which are mainly excrementitious, and a little gelatin, as well as some melted fat, although the last is often skimmed off to make the broth more pleasing and palatable. In so far as protein is concerned, a meat tea made by boiling cannot be more nourishing than egg tea, that is to say the water in which eggs are poached, or in plain words, it contains no protein nourishment at all, and is, barring certain qualitative and quantitative differences, of the same dietetic value as urine.

On such a regimen the patient may be fairly waterlogged with soup, and still get less than a hundred calories daily. If strength holds up under such feeding, it is from the reserve protein and fat stored in the body, not from any decided nutritive virtue in the soup.

It is of course wise to provide for economical use of the body fuel, just as engineers endeavor to get the most heat value from coal or wood burned in the furnaces of their engines. It is also well to minimize the surplus ashes of combustion in the body, as the engineer keeps his grates cleared of clinkers. There is, though, a point beyond which economy ceases and parsimony begins, and there can certainly be no permanent healthy growth, nor can there be maintained a normal "moving equilibrium" in the bodies of individuals or nations unless there is a liberal intake of protein food, for, as Rubner declares, "A large protein allowance is the right of civilized man."

Sir James Crichton-Browne tersely puts it thus:

The health and welfare of individuals and of peoples must depend on right methods of living, and of all methods of liv-

ing the most momentous are those relating to the up-keep of the body by alimentation. It is food that supplies the material for that perpetual series of transformations in which life consists, and it must be adequate in quantity and suitable in quality, if these transformations are to proceed with that nicely balanced adjustment that is known as health. . . . Nutrition is therefore an important branch of preventive medicine.

It may be confidently asserted that no physiologic alchemy or mathematical legerdemain can ever hope to reduce materially the fixed demand for approximately 120 gm. of protein daily for every active individual of average weight. The late Sir William Roberts once said:

The generalized food customs of mankind are not to be viewed as random practices adapted to please the palate or gratify an idle or vicious appetite. These customs must be regarded as the outcome of profound instincts which correspond to certain wants of the human economy. They are the fruit of colossal experience accumulated by countless millions of men through successive generations. They have the same weight and significance as other kindred facts of natural history, and are fitted to yield to observation and study lessons of the highest scientific and practical value.

The foregoing thoughts are respectfully submitted to the sober students of both individual and collective problems of nutrition.

A CASE OF FRACTURE OF THE THYROID CARTILAGE WITH PROMPT RECOVERY

A. C. MATTHEWS, M.D.

Assistant Physician, Hudson River State Hospital

POUGHKEEPSIE, N. Y.

Fractures of the larynx are generally considered grave injuries. When one considers the danger of suffocation from displacements of the fragments, or from edematous swelling, or from occlusion of the air-passages with blood-clots, one can understand why a case of this kind should not be looked on lightly. Fisher pronounced every case serious. Gurlt in 1864 collected reports of 69 cases in which 47 patients died and only 21 recovered. Eastman¹ quotes Durham, who collected reports of 30 cases of fracture of the thyroid cartilage, in ten of which the patients recovered, most of them after tracheotomy. During the past few years a few cases have been reported in which the symptoms were of a mild type. The "American Practice of Surgery" states that tracheotomy is not usually necessary in the simple cases and those of vertical fracture of the thyroid, but is indicated in any fracture of the cricoid cartilage. The case I observed was one without complications. Because it shows how exceedingly light the symptoms resulting from such a fracture may be I thought it worthy of publication.

An insane man (aged 49) was forcibly struck over the larynx by a fellow inmate. At the time no indications of injury were observed, and the patient went to the dining-room and ate his breakfast. Soon some hoarseness developed. This soon became more pronounced, and his throat appeared somewhat filled up with mucus. There was a constant desire to swallow. An examination disclosed a complete vertical fracture of the thyroid in the median line. Crepitus was distinct, but there was no apparent displacement. As there

were no dyspnea, and no sign of suffocation, it was thought best to immobilize the fragments and await further developments. Immobilization was secured by padding on each side held in place by adhesive strips. As swallowing caused slight movements of the fragments, the patient was allowed no food for twenty-four hours. His voice continued hoarse for four days; then there was a rapid improvement. On the seventh day the fixation strips were removed, and a perfect union was found. On the ninth day the patient was up and about as usual.

Some surgeons believe that tracheotomy should be performed immediately after such an injury in order to forestall suffocation. Eastman¹ refers to Cohen, who says: "It is better that an unnecessary tracheotomy should occasionally be performed without detriment to the patient than that a number of cases should be allowed to terminate fatally for the want of it." This is very true, but if the symptoms are of a mild type and the surgeon is in a position to render immediate service if the case demands it, one is justified, I believe, in delaying active procedure.

If the patient be allowed to swallow too early the fragments will be moved and union interfered with. Weaver's patient² attempted swallowing at long intervals during the first twenty-four hours, but this moved the fragments. Weaver then resorted to nutritive enematas for three weeks. Tube-feeding through the mouth can be used to advantage in cases in which the throat is not too sensitive, so as to cause reflex movement of the larynx.

I take this opportunity of expressing my thanks to Dr. Chas. W. Pilgrim, Supt. of the Hudson River State Hospital where this case was observed, for the privilege of reporting it.

A VOLSSELLUM FORCEPS WITH DETACHABLE HANDLES

A. HERZFELD, M.D.

NEW YORK

Occasions frequently arise when curettage, or in fact any vaginal operative interference on the uterus, has to be done without sufficient assistance. In many cases for better orientation the grasping of the uterus has to be done through a bivalve speculum. It is very difficult,

Volsellum forceps with detachable handles.

if not impossible to remove the bivalve speculum after the uterus is grasped with the ordinary volsellum forceps on account of the width of the handles of the instrument. To facilitate the removal of the speculum, I devised a volsellum forceps with detachable handles. The handles are easily applied and removed by means of a bayonet lock.

GUNSHOT WOUND OF THE CHEST AND
INJURY TO THE SPINE

WITH SPECIAL REFERENCE TO PROGNOSIS

R. T. FERGUSON, M.D.
GAFFNEY, S. C.

I report this case to furnish some idea of the prognosis to be made in cases involving injury to the spine. The literature on prognosis in such injuries is very incomplete.

History.—The patient, a colored man, aged 21, single, laborer in a railway camp, was shot July 18, 1909 at close range with a 38-caliber revolver, the ball entering the eighth interspace on the right side one inch to the right of the mammillary line, passing downward and backward and emerging through the eleventh interspace behind in the mid-scapular line $2\frac{3}{4}$ inches to the left of the spinous process of the eleventh dorsal vertebra. The man was hauled 4 miles in a wagon and 12 on train with no dressing on either wound.

Examinations.—The pulse was 130, the temperature 102, respirations 30, paralysis of the left thigh and leg was complete. There was retention of urine and paralysis of rectum with involuntary evacuations; loss of all sensation in the left thigh and leg supplied by the musculocutaneous, external saphenous, anterior tibial, external and internal plantar, and internal calcaneal and the lower part of the leg that is supplied by the lateral cutaneous and internal saphenous nerves.

Course of Case.—The patient had to be catheterized for two weeks, after which there was involuntary urination as well as defecation for six months; since that time he has improved steadily until now (twelve and a half months after injury) he can control bowels perfectly and retain his urine four to five hours. A bed-sore six inches in diameter developed over the sacral region and smaller ones over both hips, which caused a considerable amount of trouble.

Temperature ranged between 101 and $104\frac{3}{5}$ for a month, after which time it became normal. After two months the patient could move the toes slightly, then the foot, knee and thigh; and six months after the injury he could move the entire leg a small distance in every direction. August 9, 1910 he is walking around quite well without the use of his crutch and gives every indication of an early and complete recovery. The injury to the spinal cord appeared to be limited to the direct pyramidal tract and antero-lateral column in the left side of the cord.

800 Limestone Street.

Bilateral Herpes Zoster.—Dr. Lester C. Diddy, Oswego, Ill., writes: Reading the article in THE JOURNAL (July 30, p. 372), by Drs. Varney and Jamieson brought to mind a similar case, which occurred in my practice recently, of which the following is a brief report: Mrs. S., housewife, aged 54, American, whose family history is negative, as far as anything bearing on the present condition is concerned, had the ordinary diseases of childhood, since which time she has been healthy. There is no history of injury at the site of eruption. Pain of neuralgic character appeared several days before the lesions, which were typical of herpes zoster. They first appeared on the left side, in the dorsal region near the mid-axillary line, and gradually extended over nearly the entire left half of the chest and abdomen anteriorly and posteriorly. Lesions appeared on the right half of chest and abdomen and extended until they met those on the left side, completely girdling the patient. The lesions became very extensive and caused no little annoyance. They extended upward to the second rib in front and to the scapula behind, downward to the groin on the right side, and about half way down the left thigh, and down the back as far as the buttocks. The inner surface of the left arm was also affected, nearly to the wrist.

CASE OF A SPOOL EMBEDDED IN THE
CERVIX UTERI

A. P. STONER, M.D.

Instructor in Surgery Medical Department, Drake University. At-
tending Surgeon Mercy Hospital.

DES MOINES, IOWA

History.—S. L., aged 16, colored, entered my service at the surgical dispensary of Drake University, July 14, with a history of pelvic trouble of some years standing. She menstruated at 13 for 5 successive periods, after which time the period ceased altogether.

Examination.—Her general condition and appearance was good and she was of average intelligence. On investigation the underclothing was found to be saturated with urine and the vulvar region was excoriated. A vegetative growth of small size and of a reddish hue, surrounded the meatus, and urine was trickling from the vagina. The examining finger came in contact with a foreign body in the vagina, which proved to be a wooden spool. Further examination showed that one end of the spool which measured about 5 centimeters in length, was securely embedded in the cervix. The free end was grasped with a pair of forceps and an attempt made to extract it, but this effort created great pain, and chloroform was administered. A more complete examination was

Drawing to show position of spool before removal, with infantile uterus and fistulous tracts from bladder and uterus into vagina.

then made. The uterus was retroverted and its body atrophied. The cervix held the spool tightly, about its middle third. One edge of the upper end of the spool through pressure necrosis, had worked its way through the uterine tissue back into the vagina.

Treatment.—As it was impossible to extract it forcibly or to dilate the canal the cervical tissue was divided at this point and the spool released.

Remarks.—The free end of the spool was covered with calculeous salts and its upper edge had protruded into the base of the bladder, creating a vesico-vaginal fistula, through which the index finger could be freely passed. The girl denied all knowledge of the presence of a foreign body in the vagina, but stated that when she was about 8 years old her mother, who was very unkind to her, had placed something in the vaginal canal which gave her great pain and caused hemorrhage for a few days. She has had more or less discharge ever since, she claims, but it was not until 8 or 9 months ago that the urine began to pass through the vagina.

The length of time the spool had been in the uterus, and the manner in which it had become embedded

therein are of interest. Conception and abortion were denied, and excluding the latter, the only plausible solution seems to be, that the spool was inserted by the patient into the vagina, and as she was probably unable to remove it, the upper edge of the spool by constant pressure against the external os produced sufficient dilatation to allow the spool to pass into the cervical canal. This new position assumed by the spool then caused retroversion of the uterus, while its presence interfered with the nutrition and growth of the organ. The opposite end of the spool also assumed a more intimate contact with the bladder wall, causing pressure necrosis and a fistula. The walls of the vagina were found to be thickened, very nodular and much reduced in depth.

CONCUSSION OF THE BRAIN

ALFRED REGINALD ALLEN, M.D.

Lecturer on Neurologic Electrotherapeutics, Instructor in Neurology and in Neuro-Pathology at the University of Pennsylvania

PHILADELPHIA

In this day and generation a justification is desirable when a single case is reported. This is particularly in order when the case is one of cerebral concussion. Nevertheless, on account of the extraordinary symptom-complex and course of the case in question, I offer no apology for its presentation.

History.—August 6, 1910, E. D., male, aged 6½, weight 49 pounds, in robust health, fell while running on the porch, striking the left side of his head. The time of the accident was about 4 p. m. Judging from the position of the ecchymosis, which was very slight, the point of impact must have been about 4 cm. above and 2 cm. behind the external canthus of the left eye.

I saw the child within ten minutes of the accident. The nurse said that after he fell he got upon his feet immediately, crying lustily. He was very pale, and the nurse thinking that he was more scared than hurt, sought to pacify him by walking. He had not gone far before he said: "I can't see anything but sky."

Examination.—My examination revealed the following condition: Total blindness in both eyes for both form and light. A lighted candle held 25 cm. from his eyes in a darkened room gave no visual impression of light. The irides reacted to light. All extraocular movements were perfectly normal. The hearing in each ear was normal. The tongue was protruded in the median line. There was no involvement of the facial muscles, and the elevation of the soft palate was normal and symmetrical. The movements of the upper and lower extremities were normal in all directions. The reflexes of the upper extremities were normal and no spasticity was present. Both knee jerks were greatly exaggerated, and although there was no ankle clonus present, yet the sudden flexion of the foot at the ankle provoked one quick reflex extension movement. Passive movement of the lower extremities demonstrated a very decided degree of spasticity. Normal plantar reflex was present on right, but a well marked Babinski reflex was elicited on the left. The pulse was full but irregular, and at the rate of 63 to 72 per minute. The breathing was deep and sighing in character, and at the rate of 16 per minute. He answered questions readily, and showed great mental distress because he was afraid he would never see again. After the examination he quickly went to sleep. He could be aroused from this sleep, and showed no predisposition to lie on either side. During this sleep the breathing still maintained the deep sighing character.

I made my second examination about one hour after the first, at which time all the symptoms as above recorded were present, with the exception that on testing the eyes with the candle he said that it seemed a little lighter when the candle was placed 25 cm. in front of his eyes. The Babinski reflex

on the left at this examination was pronounced. In a half hour from this time he called a lighted candle a lighted match. In another half hour, two hours from my first examination, he was able to recognize a lighted candle as such, but could not distinguish objects, such as a pair of scissors, knife, picture, etc. From this time on his eyesight returned with great rapidity, and three hours after my first examination he was able to distinguish objects and people with great precision. On account of his general condition I did not make any examination of his visual fields at this time. His temperature never went above 99.4 F. At 10 p. m. I found his vision normal, pulse 72, temperature 98.4 F., respiration 18. At this time I found the Babinski reflex on the left hard to elicit but questionably present. The chief symptom at this time was vertigo on motion.

Subsequent Course.—The next day he felt perfectly well except for the vertigo which was present when he was propped up too erectly in his bed. He had an attack of nausea and vomiting at 5 a. m. A careful examination for hemianopsia, astereognosis and lack of sense of position in the limbs proved negative. His reflexes were all normal and the Babinski reflex on the left was replaced by normal plantar flexion. The recovery was uninterrupted, and four days after the accident he was leading his normal life. There was never any disturbance of bladder or rectal functions. The only therapeutic treatment was magnesium sulphate to open the bowels.

The case is interesting on account of the rapid clearing up of the complete blindness, the sudden causation of the monolateral Babinski reflex, which cleared up within eighteen hours, and the very evident interference with the spinal reflex inhibitory mechanism with no symptoms of compression.

After writing the above report, the *Deutsche medizinische Wochenschrift* (August 4, 1910) has come to hand, in which is a short paper by Hirsch of Prag ("Ueber passagere Rindenblindheit durch Commotio cerebri"). There is no mention of any examination for involvement of the central nervous system, other than a careful examination of the eye. He cites Wildbrand and Sänger ("Die Neurologie des Auges") as having collected seven cases of similar nature.

111 South Twenty-first Street.

Therapeutics

GENERAL PRINCIPLES IN THE MANAGEMENT OF DISEASES OF THE HEART

As has been a number of times stated in these columns, with all our knowledge of physics, of cardiac ability and cardiac disability, of blood pressure, of arteriosclerosis, of myocarditis and cardiac muscle degenerations, with all our better knowledge of physical therapy and of the pharmacologic action of drugs, still there are no defects of mankind that are so many times mismanaged and mistreated as are cardiac defects. They are mistreated from the very fact that the drugs and methods used are powerful for good or bad, and not only may the wrong method be instituted, but too much or too little of the method or treatment may be used.

Sir James Barr, of Liverpool (*British Medical Journal*, April 24, 1909) discusses the above subject and especially urges the attempt to prevent the development of serious disease of the heart in various conditions, and especially to prevent that which is due to rheumatism. He states a fact, viz., that though the majority of sudden deaths are due to a cardiac cause, still there are very few chronic diseases so amenable to treatment and so compatible with long life and comfort, if judiciously handled, as are diseases of the heart.

As a prevention of heart disease he properly urges the prevention of rheumatism in the children of families who have shown a tendency to it. Although rheumatism is doubtless always an infection, still, like the development of tuberculosis, there is a tendency to or an inherited lack of ability in certain families to combat this particular germ. Hence Barr believes that such children should always be warmly clothed, that they should have daily baths, either warm or cold, to keep the skin in good condition, that proper fresh air and physical exercise should be taken, that they should not over-eat or over-drink, and that the bowels should move freely, daily. This simply means first class, sensible hygiene aiming to prevent poisoning with food products, and to cause increased circulation in the muscles and therefore less pressure internally, and to promote perfect functioning of the skin. The parents of children who are likely to have rheumatism should be especially cautioned to take note of everything in the line of so-called "growing pains." As there is "an increase in the formation of sarcolactic acid and all the excretions are very acid in rheumatic fever," Barr would prevent this increased acidity of secretions of possibly rheumatic children by omitting starch and milk from their diet. He believes that milk forms lactic acid during digestion. As a matter of fact, probably, in healthy digestion milk does not form lactic acid. Still such is his belief that he would not give such children milk. Also in rheumatism there is a great tendency to form fibrin; hence he would give nothing to such children that contained lime, and he would cut out of the diet cheese, gelatin and animal jellies, as well as milk. As lime also raises the blood pressure, he thinks that milk is a bad diet during rheumatism, and has condemned it since 1886. He gives as a diet in rheumatic fever plenty of hot water, chopped meat, poached eggs, thoroughly cooked oatmeal gruel, oranges and lemons. After the acute attack is over he varies the diet by allowing a certain amount of farinaceous food, plenty of fruit and vegetables, but he still prohibits the milk. Such a diet in rheumatic fever is certainly different from that generally followed, but he believes that he may thus prevent cardiac complications.

A patient who is rheumatic and is putting on flesh and getting fat and flabby should immediately have his food amount reduced and his diet so arranged that he will not only not increase in weight but that he will lose what is superfluous. Barr urges what is also very essential, especially if the patient has a defective heart, that the liquid be reduced to two pints a day, or even less, if this does not so deplete the tissues that some of the fat is resorbed. Patients with valvular lesions should not use tobacco at all, should take but little tea and coffee and, if there is any edema, even if the kidneys are not affected, should cut down the amount of salt in their diet.

If endocarditis has developed, the blood pressure should be kept as low as possible with a prolonged rest in bed, but as soon as the heart muscle improves the patient should be allowed to get up and gradually begin ordinary exercise, as anything that brings the blood to the muscles and dilates the surface capillaries is a relief to inflamed parts that are trying to heal permanently. While the patient is in bed after the rheumatism has ceased, massage should be daily given, to do what can be done to stimulate the muscular circulation. After the patient has permanently recovered graded exercise, mild hill climbing, etc., should be advised, but Barr does not believe in any such strenuous work for an in-

competent heart as advised by Oertel. Marriage, he thinks, especially of females, should be prohibited when there is valvular disease of the heart.

As the left side of the heart has the most work to do, it is its valves that are most likely to be permanently damaged by an endocarditis, and anything that aids the plasticity of the blood, as calcium in any form, and anything that increases the blood tension, which puts the most work on the left side of the heart should be interdicted. Respiratory exercises are valuable as aiding the right side of the heart.

Cardiac disturbance caused by diphtheria and typhoid fever is more myocardial inflammation than endocardial, and in both these conditions the blood pressure is generally low enough from the disease. The heart readily dilates and becomes weak but the valves are not injured. Here lime salts as present in milk are advisable and will do good, although an injudicious amount of milk, as any other liquid in injudicious amount, is a mistake in any weakened condition of the heart. Barr thinks it quite possible that the tendency to arteriosclerosis after typhoid fever may be due to an injudicious amount of calcium administered with milk during the fever process. Although we are firm believers that about a pint of milk is sufficient per diem for a typhoid patient and do not believe in the enormous quantities of milk that have been given in this fever, it hardly seems probable that the little calcium in milk, or even the lime water that may be added to the milk, could be a cause of arteriosclerosis so often seen to follow typhoid fever.

The failure of the heart in diphtheria is partially due to disturbance of the pneumogastric nerve, and such a heart needs a tonic, not only lime but iron and possibly digitalis. The same cardiac depression as seen in diphtheria, although not as acutely serious, may show itself in influenza, where cardiac debility is prolonged and tedious. This is probably a nervous debility. Here lime is valuable; also strychnin, atropin, and perhaps digitalis.

Whooping cough injures the heart physically and is likely to injure the right side, and in whooping cough Barr advises the administration of atropin or perhaps other cardiac tonics. In all cases of whooping cough it is advisable, as long as the cough is severe, to administer digitalis regularly in such doses as meet the requirements of the child's age and condition.

In any infective endocarditis an autogenous antitoxin cannot be too soon developed, as such a complication shows that the disease is beyond almost any other control.

Barr states what is so well understood by physicians but so little understood by the laity, viz., that chronic heart lesions of all kinds are extremely amenable to treatment. This means that generally for years a patient may lead his ordinary life provided he will follow out the rules and regulations advised. Of course, sooner or later every diseased heart is beyond repair, but even in the worst instances amelioration of symptoms is generally for a long time possible. Moderate exercise, Barr urges, brings the blood to the muscles and relieves the inner tension and prevents the development of chronic disease of the organs from continued internal congestion. Excessive exercise is, of course, serious and should be interdicted because of the sudden extra work put on the heart. Large eating of any kind is inadvisable, and especially is it inadvisable to eat too much protein, as the blood loaded with insufficiently oxidized protein products can do nothing but debilitate the heart muscle and irritate the arterioles to greater

contraction and thus put more work on the heart. While at many so-called "cures" enormous amounts of water are administered to flush out the system "as though a sewer was to be cleaned," the inadvisability of loading up the circulation, especially the venous circulation, with extra amount of fluid is readily understood from a physical standpoint; it can sooner or later do nothing but harm. This of course is especially true if there is edema or a tendency to edema, to say nothing of general anasarca. It is so much more sensible, in conditions of internal congestion, to diminish the food, give a small amount of liquid, to gradually eliminate toxins from the system, and then to prevent more toxins from being formed.

Barr well says that he does not believe in any routine system in the treatment of chronic heart disease, but the patient should be individualized: the amount of exercise, hot baths, sweatings, food, and drink that one patient should take is not at all a criterion of what will be of benefit to the next patient.

We can but agree with him when he urges the necessity, in lack of compensation in valvular disease or in an acutely weak heart from any cause, for absolute bed rest, in fact, complete repose, not even rising to dress. It certainly is no time to consider exercise when a patient has great loss of compensation, as is shown by edemas, dyspnea, albuminuria, nosebleed, petechiae, profuse menstruation or even uterine hemorrhage, or bleeding from the lungs. It may generally not be advisable to have the patient absolutely flat in bed during the whole day; even if he can lie on one pillow, it is advisable several times a day to have him recline on two or three or even four pillows. This is all the exercise the heart requires until it becomes stronger. A diminution of the liquid taken, and especially the withholding of salt (sodium chlorid) and the administration of just sufficient nutriment to provide for nutrition, and a daily evacuation of the bowels will, even without cardiac tonics, often cause diuresis and an absorption of the fluid extravasations. If in spite of an improvement of the arterial circulation the circulation of the veins is sluggish and the edema, especially of the extremities, is not readily removed, Barr suggests bandaging the extremities.

When the heart muscle is not much diseased, advanced arteriosclerosis is not present, and the heart is dilated, there can be no question of the value of digitalis in most instances. The arterial blood pressure should, however, be carefully noted, and if this is high digitalis is not the drug to administer. If it is low, digitalis is generally the drug to be used. The amount must depend on the tolerance of the patient and the results obtained. The dose should not be too frequent; two or three times in twenty-four hours is sufficient, as it is slowly excreted. If the blood pressure is high or there is much arteriosclerosis, or if the lesion is an aortic lesion, many times the vasodilators are the drugs most efficient. Sometimes digitalis causes digestive disturbances sufficient to prohibit its use, and if digestive disturbances are not in evidence it may cause headache; and yet the blood pressure may be so low as to contraindicate the use of vasodilators. In such apparently hopeless cases which are often accompanied by pulmonary congestion from failure of the right ventricle, often accompanied by the expectoration of bloody sputum, sometimes an actual venous hemoptysis, no treatment is as valuable as the so-called hot air treatment or "body bake."

While repeated baths are almost always advisable in heart disease, and while the Turkish bath will often cause sufficient elimination to improve the circulation, it can do harm, but the body bake, with the head exposed to the fresh, clean air, and the peripheral circulation of the body dilated and profuse perspiration caused, all under careful supervision of the pulse by an expert, will relieve internal congestion, reestablish and equalize the circulation, and cause a return of compensation when all other means have failed. Also, in conditions of failing heart due to arteriosclerosis no amount of dilators or other treatments will reestablish the circulation and give a prolonged amelioration of symptoms and apparently perfect health as will the body bake. The blood pressure will be reduced by this means and remain reduced for months under proper simple regime, after it is once brought down by the body bake. Such baking should not be too frequent, possibly every other day for once or twice, then once in five days or once a week, combined with at first rest in bed, then gradual convalescence, and then graded exercise.

If a patient, for any reason, must remain long in bed, massage must be done daily to keep the muscles in proper condition, to keep the circulation in the muscles normal and to relieve the internal congestion.

The expectation of forced diuresis alone doing much good in cardiac failure with anasarca is generally without justification. Under the management suggested albuminuria, which is caused by the chronic congestion of the kidneys from a bad heart, is relieved, and as soon as this congestion is lessened an increased output or urine takes place without a diuretic.

Barr urges the danger in anasarca from failing heart, even with almost anuria, of causing profuse watery evacuation of the bowels with any cathartic. Many a death is thus caused by the depletion and weakening and the terribly low blood pressure caused by salines.

Any bath treatment that equalizes the circulation and brings the blood to the surface and relieves internal congestion, or stimulates sweating and causes increased capillary circulation, whether the carbonic acid bath, the Nauheim bath, or any massage, will almost always aid in improving the circulation in heart disease.

It would prolong this article too much to discuss the relative values and relative indications for the cardiac tonics and stimulants other than digitalis, or to discuss the various methods of producing dilatation, or the best method of treating angina pectoris and cardiac pain and irregular and intermittent heart action, but it should be urged that alcohol is not a real cardiac stimulant; that tobacco always weakens the heart muscle; that any excess of lime is contraindicated in arteriosclerosis and when there is an increased coagulability of the blood or a tendency to plastic exudates.

Ethics.—Standards of ethical conduct—that is, conduct which not only extends to the development of individual character but also to that of the well-being of the race—have undergone considerable evolution, the most potent single influence which has been brought to bear on them being Christianity. "An eye for an eye and a tooth for a tooth" of the Jewish law, is supplanted by the offering of the other cheek to the smiter, of the Christian dispensation. Taking the world as a whole, even to-day, external standards vary enormously with the degree and kind of civilization—and its lack—with the religion and organization of society, the physical peculiarities of a country, the density of population, means of communication and a thousand other things.—F. B. Shattuck, in *Cleveland Medical Journal*.

SATURDAY, SEPTEMBER 10, 1910

CHOLERA AND CIVILIZATION

The reappearance of cholera in Europe raises again the question whether the twentieth century, like the nineteenth, is to witness pandemics of this disease sweeping over Western Europe and even extending at times into the United States and Canada. Fortunately we now possess very definite information concerning the modes of spread and usual vehicles of infection of this once greatly dreaded malady. It is, for example, an incontrovertibly established fact that a sewage-contaminated water supply is responsible in practically all cases for the epidemic prevalence of cholera. Scattered cases of the disease may occur in a city with a pure water supply, but no general and widespread infection need be feared so long as the water supply remains uncontaminated.

The sudden outbreak of cholera which occurred in Hamburg in 1892, and which attacked about 17,000 persons and carried off 8,600, might well have been predicted by sanitarians on the basis of the known facts regarding the entrance of sewage into the river water from which Hamburg obtained its supply and the significant prevalence of typhoid fever in that city. So too at the present day, if cholera should become at all widely distributed in this country, we could predict with a high degree of certainty those sections of the country and even the communities that would suffer most severely. Cholera in even greater proportion than typhoid fever is a water-borne disease.

Almost any article of food or drink may occasionally serve as a medium for conveying typhoid infection. Of course such substances as milk, vegetables and fruits consumed without cooking are to be regarded as particularly dangerous, but any food handled or kept under uncleanly conditions may be the means of introducing cholera vibrios into the intestine. Flies fed with cholera-infected material have been found to contain the vibrios in their intestines for as long as fourteen days.

"Cholera carriers" have been shown to exist in the persons of healthy individuals resident in districts where

the disease prevails. There seems no doubt that cholera spreads from locality to locality not by bales of merchandise, but by the carriage of the specific germ in the body of man himself. Dunbar has stated that in the Hamburg epidemic of 1892-93, he was able to detect the cholera vibrio in no fewer than twenty-eight persons who were entirely healthy and had never manifested any symptom of cholera or had suffered the slightest attack of diarrhea.

The immediate practical deduction from these facts seems plain. It is more rational to expend our efforts in improving general sanitary conditions in this country than to establish a shotgun quarantine and attempt—probably in vain—to prevent any person harboring cholera vibrios from landing on our shores. Attention to the ordinary demands of civilization, the elimination of sewage from our water supplies, the insistence on clean milk and bread, the banishment of the common drinking-cup and the roller-towel, the extermination of the house-fly and other vermin, the observance of a decent degree of cleanliness in the streets and in the house—such measures will go far to avoid the danger of cholera epidemics now and henceforward. More than once has it been shown that in default of an efficient system of national and municipal sanitation, quarantine is but a broken reed. The British sanitary system makes a clear recognition of this principle. Nearly twenty years ago a distinguished British official wrote:

"For England the abandonment of quarantine has been an almost unmixed good. The knowledge that no pretense would be made to keep out all chance of cholera in this country, has done more perhaps than anything else to induce our sanitary authorities to spend their money on great works of sanitation and on such improved sanitary administration as is likely to prevent the spread of any imported disease of the type of cholera. Millions have been spent to this end; but, on the other hand, hundreds of thousands of lives have been saved. Even if cholera should once more succeed in passing the barrier of our ports and, diffusing itself inland, cause a heavy mortality, we should still be enormously the gainers in point of human life by the system which we have so deliberately adopted, but there is no doubt that our system is rather calculated to prevent than to lead to such a contingency."

Local isolation and general sanitation are the most effective defenses against cholera, as against typhoid fever and many other infections. To use a simile of Pettenkofer's, insanitary conditions may be looked on as a kind of powder for which cholera is a spark; it is a much wiser procedure to see to it that we allow no such inflammable powder to accumulate than to spend our efforts in frantic attempts at beating off the spark.

SEWAGE DISPOSAL BY DILUTION

It is often considered a procedure far from ideal to discharge sewage without treatment into the nearest large body of water, whether ocean, lake, or river. Yet many municipalities are so situated that this is the least expensive course open to them, and it is not surprising that hard-pressed city administrators find the least costly way the most tempting. On the public health side this method of sewage disposal always raises two questions: first, whether the degree of dilution proposed is sufficient to avoid offensive decomposition, and second, and more important, whether the procedure involves contamination of the city's own water-supply, or of that of any other municipality. Where either of these conditions can be shown to exist exception must be taken to this mode of sewage disposal.

In this country, many cities situated on the Great Lakes have long made a practice of discharging their sewage directly into the lake water at the most convenient point. Unfortunately these cities have also drawn their drinking supply from the same body of water within a few miles, or even a few hundred yards, from the sewage outfall. The result has been that, as is well-known, in times past several of these cities suffered severely from water-borne disease. Buffalo, Cleveland, Chicago, Toronto, Milwaukee, and other cities, have all at various times had occasion to deplore the close connection between water-supply and sewage disposal. It may therefore come as something of a surprise to find leading sanitary experts, including the chief engineers of the state boards of health of Massachusetts, New York and Pennsylvania, giving their sanction to a proposal to discharge the raw sewage of Rochester, N. Y. (population about 200,000) into Lake Ontario. The local features that have led to such recommendations are worth noting as an illustration of the fact that under proper conditions sewage disposal by dilution may be legitimately practiced.¹

At present the Rochester sewage passes into the small Genesee River, which flows into Lake Ontario and at certain seasons is greatly overburdened, so that a serious nuisance is caused. The new plan proposes to discharge the sewage, after a slight period of sedimentation followed by screening, directly into Lake Ontario in water 55 feet deep, 7,000 feet from shore. The proposed outlet is about three miles from the Rochester and Ontario Water Works, but according to the opinion of the sanitary engineers, the process of filtration to which the water is subjected renders danger of infection very unlikely and in no case greater than at present. It is also the belief of the experts that the likelihood of contamination of the Oswego water-supply, 50 miles distant, is too remote for practical consideration. The degree of dilution outlined under this project, is sufficient to avoid any possibility of a nuisance.

Altogether the reports of the experts in the Rochester case constitute a strong endorsement of the principle of sewage disposal by dilution. No water-supply is threatened, a present nuisance is abated, and no fresh nuisance created. Given suitable conditions, such as seem to exist at Rochester, it must be admitted that sewage purification by dilution may be a safe and legitimate solution of the sewage problem.

ORGANIC ARSENIC PREPARATIONS—EHRlich's 606

The prominence into which organic arsenic compounds have again been brought by their application to the treatment of protozoan diseases, such as sleeping sickness, and, more recently, syphilis, makes it seem desirable to call attention to a few fundamental facts which are apt to be overlooked. Merely to warn¹ against the ready acceptance of optimistic preliminary reports in a general way is not sufficient; it is better to consider the principles underlying the action of these substances and to base our warning on well-known difficulties.

The action of organic arsenic compounds is fundamentally an arsenic action and depends on the destruction of the organic radicle, with the liberation of the inorganic portion. Against this view may be cited the clinical observation that the use of inorganic arsenic preparations is not attended with the same success as can be obtained with the more special preparations, such as atoxyl, or more recently "606." This difficulty can be easily understood, however, when we consider that the efficiency of such compounds depends on their specific affinity for the protozoon, in other words their ability to enter the protozoon in preference to the tissues of the host. After they enter the protozoon their action is essentially an arsenic action, but their specificity of distribution between the invading organism and the host depends on the structure of their organic radicle. In the course of a search for such specific differences a vast number of preparations have to be examined, as the above number, "606," would indeed suggest.

The dangers and the difficulties in the practical application of these compounds, which recent work has disclosed, are due to two facts, careful attention to which is necessary on the part of everyone wishing to form a fair judgment. In the first place Ehrlich has found in treating trypanosome infections, that a certain proportion of the protozoan are tolerant to the arsenic preparation. The well-known difficulty—the incomplete destruction of the invading organisms—encountered in treating a case of mixed infection in malaria is here rendered more difficult by the fact that even under the most favorable conditions it is impossible to destroy completely all the invading organisms. This fundamental difficulty has not yet been overcome and is very likely to apply to the similar case of the spirochete of syphilis.

1. Engineering News, Aug. 11, 1910.

1. THE JOURNAL, Aug. 13, 1910, p. 601.

From this difficulty arises the second complication, the danger of giving these substances in overdose. This danger is particularly prominent with organic arsenic preparations, on account of the large amounts which can be given before the arsenic action is apparent, and on account of the great difficulty in making an early diagnosis of arsenic poisoning. When we consider the difficulties that have been encountered in the recognition of such well-known cases of arsenic poisoning as the Manchester epidemic, poisoning by ferrosilicon,² and a number of criminal cases, obscure until chemical analysis revealed the cause, the very great danger likely to arise from this source will be apparent. Some who are familiar through long use with Fowler's solution may be inclined to minimize this danger. We must remember, however, that Fowler's solution is very soluble and easily eliminated while the very nature of organic arsenic compounds depends on their ability to show more or less of a cumulative action. This cumulative action may lead to the well-known symptoms of chronic arsenic poisoning, among which peripheral neuritis accompanied by blindness is perhaps the most apparent, although a great many more obscure complications due to injury to the capillary walls are also apt to occur. In the use of atoxyl in sleeping sickness, several cases of blindness have been reported.

This criticism is not intended to be destructive but rather constructive. If arsenic compounds are destined to give us the long-sought specific for syphilis, the final decision as to its usefulness must depend on the results of clinical experience. During the experimental period, however, attention should be directed to the two principal points here outlined: the completeness of the destruction of the invading organism, and the careful control (preferably by quantitative estimations) of the arsenic eliminated during treatment to avoid the danger of cumulative action. Professor Ehrlich's caution in guarding against the general use of his preparation cannot be too highly commended.

Current Comment

OSTEOPATHS CANNOT SIGN DEATH CERTIFICATES

A New York court has decided that local boards of health cannot recognize death certificates issued by osteopaths until a coroner has made an investigation. The decision sustains the position taken by the corporation counsel of the City of New York. In rendering the decision, Judge Putnam said, "While the state has wisely allowed the practice of osteopathy, it does not follow that it thereby holds one without any practice in surgery or experience in prescribing drugs as fully qualified to certify the cause of death... The sanitary code is discriminatory but the discrimination is not personal or arbitrary. It is based on a limitation which the

osteopath may be said to make for himself and deprives him of no right he ought to exercise consistent with the public safety." The essential point in the decision is Judge Putnam's statement that the limitations of osteopathy have been made by the osteopath. Whenever an osteopathic bill has been before a state legislature, the osteopaths themselves have been most vehement in their declaration that they were not physicians and that osteopathy was not the practice of medicine, consequently they could not be made amenable to medical practice acts. Yet as soon as the osteopathic bill is passed, they demand the privileges of legally qualified physicians. The personal practice of osteopathy is comparatively unimportant. The recognition of osteopathy, scientifically and economically, is a most important matter. Osteopaths, as a class, must accept one of the horns of the dilemma. If they are physicians practicing medicine and surgery, then they are amenable to medical practice acts and there is no justification for allowing them to practice medicine and surgery on a basis of qualification lower than that exacted of other practitioners. If they are not physicians and if they are not practicing medicine, then they cannot expect to exercise the functions of legally qualified physicians. While the decision referred to above is not final, the ruling is so clearly in line with common sense and logic that it will undoubtedly stand.

AMERICANIZING OF FOREIGN NAMES

The Prussian Minister for Commerce and Trade urges that a German becoming a citizen of the United States should retain his original name rather than Americanize it. While this recommendation doubtless was inspired by a commendable spirit of patriotism, it is also to be endorsed on practical grounds. The changing of names indulged in by many of our foreign-born citizens, as well as by their children, has a confusing effect in tracing lines of descent, family connections, relationships, etc., especially on public records and documents. The matter is of medical interest because it frequently happens that a medical student of foreign birth or parentage graduates from a medical college under one name, receives his state license under another, and in a few years is practicing under a third designation. The names may either be variations of the original or in some cases entirely different, with much confusion in personal identity as a result.

PRESIDENT TAFT ON PUBLIC HEALTH LEGISLATION

The efforts of certain interested individuals to make it appear that the President has withdrawn from his position on advanced health legislation have been nullified by the latest utterance of Mr. Taft. In a letter carefully prepared for publication in the Republican Campaign Handbook the president enumerates the measures to which the Republican party stands committed. The letter may be regarded as representing not only the personal views of the President but the position of the party also. "As to future legislation," the President says, "a number of promises remain to

be kept." After alluding to important commercial and economic measures, he continues, "There is also the promise of the Republican platform to make better provision for securing the health of the nation. The most tangible and useful form that this can take would be the establishment of a National Bureau of Health, to include all the health agencies of the government now distributed in different departments." The public health plank of the Democratic platform of 1908 was even stronger than the declaration of the Republican platform. The proposed federal health legislation is being supported without regard to political affiliation. The question is in no sense a partisan one. It is simply a problem of method—a problem of the best way to unite and strengthen existing health agencies of the government. Mr. Taft's recognition of the obligations of his party and of his administration with regard to health legislation will go far toward making possible the passage of a satisfactory law in the near future.

BUDDING ELOQUENCE

In a periodical published by a medical students' fraternity we find this gem: "If men and women will awaken from their sleep of apathy, throw aside the mantle of inertia, wash from their eyes self-centered indifference to needed reforms, and try to get nearer to that utopian time when man will really love his fellow-man and will strive to do unto others as he would have others do unto him, then will the child be really given a fair chance. With such a resolve for the future, with enlightenment, justice and liberality for guides it can be accomplished, and a race of people of such moral, mental and physical excellence be developed as to render Earth nigh akin to Heaven." Note the prodigal extravagance of the first sentence, in which the author feels able to afford four figures of speech. And yet again, note the beautiful progress of the figures: to awaken from sleep; to throw aside the *robe de nuit*; to perform one's morning ablutions—what a realistic touch! Surely we have here a coming medical poet.

YELLOW FEVER

In the United States and Cuba, at least, yellow fever has become almost a historical disease. Not so much can be said, however, for the Central and South American countries. The gulf states, realizing this, and anticipating a large increase in commerce with the southern countries with the completion of the Panama canal, with commendable caution are keeping in view the possibility of a return of this scourge to their cities and towns. The *Gulf States Journal of Medicine and Surgery* in commenting on a paper by Dr. Charles A. Mohr, on the symptomatology of yellow fever, which it publishes, urges physicians practicing in the gulf cities to familiarize themselves with the symptoms of this disease and to make a searching examination of every case of fever occurring from August to November so that the disease may not gain a foothold. It suggests that while

the U. S. Public Health and Marine-Hospital Service is performing an invaluable service in preventing the introduction of the fever into the South, the gulf cities are not doing their full duty in destroying the stegomyia and their breeding-places so that yellow fever could not spread if it once gained entrance. It is the "swat" of the mosquito in time that saves nine lives.

EHRLICH'S SYPHILIS REMEDY NOT YET ON THE MARKET

In view of the far-reaching consequences of that dread disease, syphilis, and especially in view of the remarkable success which is reported to have attended its treatment by Ehrlich's arsenic preparation, it was only natural that the announcement of this remedy should have created intense interest and a demand for the substance. We have heard of a number of men starting for Europe, to endeavor to see Ehrlich and to secure some of the remedy. Hundreds of others doubtless have written him. One letter was sent in care of THE JOURNAL to be forwarded, because the writer had only the word "Frankfort" for Ehrlich's address and questioned whether this meant "Frankfort, Ky.," or some other place. Without doubt, Professor Ehrlich has received more letters than he is at all able to answer. It is fitting therefore, for us to warn the profession in the words of a cablegram just received from one of THE JOURNAL's foreign representatives:

"Ehrlich says doctors stay home, don't write; 606 market November."

In other words, the remedy will be ready for distribution in November, and at present, physicians will find it useless as well as annoying, both to themselves and to Professor Ehrlich, to write to him or to go to Europe to see him. One who saw a similar concourse waiting on Koch after his great announcement, described it as such an embarrassing throng that even eminent men had difficulty in securing an audience. Practically everyone there had wasted his time in going. The warning is a timely one. In the interim, THE JOURNAL will continue to keep its readers fully informed on the subject.

HOW THE RELIGIOUS PRESS ASSISTS IN HUMBUGGING THE PUBLIC

"Vitæ-Ore,"¹ according to its exploiters, is the "dried residue of the greatest curative spring in the world"; according to Bulletin 69 of the North Dakota Agricultural College Experiment Station, it is a mixture of Monsel's and Epsom salts. The marvelous (commercial) possibilities of this preparation—it sells at a dollar a package—were "discovered" by one Theophilus Noel, who is said to have at first peddled the nostrum in order to get a start. Soon, an advertising campaign was instituted in religious papers and was kept up with great persistence. As business increased, a British depôt was opened in London and the clergy of that

1. See also THE JOURNAL A. M. A., Feb. 2, and 16, 1907; also Propaganda for Reform, page 208.

country received letters from the concern in which the personality of Christ was used to boom the sale of the nostrum. Evidently this combination of piety and quackery has proved profitable. The newspapers of a few days ago contained an item regarding the divorce suit brought against Theophilus Noel—referred to as "the millionaire 'patent-medicine' manufacturer"—in which the wife testified that it would be impossible for her to live on less than \$500 a month at Noel Heights, the California residence of the nostrum vender. She said that it would cost that much to keep up the premises and pay the servants. With the domestic affairs of this enterprising promoter of modified Epsom salts our readers are not interested, but the testimony quoted is striking evidence of the value of well-advertised piety as a "patent-medicine" asset. To the religious press of America, more than to any other one factor, Mr. Noel owes his financial success; to such satisfaction as this particular field of journalism may derive from this fact, it is more than welcome. Fortunately religious papers are awakening to the iniquity of the whole wretched "patent medicine" business and the advertising field for such preparations as Vitæ-Ore is becoming daily more restricted.

ELECTIVE MEDIA FOR CHOLERA VIBRIOS

The appearance of cholera in Western Europe adds interest to the attempt to discover a culture medium which shall facilitate the isolation of the cholera vibrio. An attempt of this sort was made a short time ago by Dieudonné,¹ who took advantage of the well-known tolerance of the vibrio for alkali. The blood-alkali-agar prepared by him has been tested with favorable results by Huntermüller² and others. Still more recently Neufeld and Woithe³ have published results of work with the medium and have somewhat extended Dieudonné's observations. These latter authors find that ordinary agar rendered strongly alkaline has the same effect in suppressing *B. coli* and in producing a characteristic cholera vibrio colony that Dieudonné's medium is credited with. Indeed they declare that simple alkalization of peptone water with potassium or sodium hydrate (0.7 to 0.8 per cent. normal solution) affords a medium that possesses some advantages over the alkaline agar.

Medical News

GEORGIA

Resolutions Regarding Dr. Calhoun.—A committee of the board of trustees and the faculty of the Atlanta College of Physicians and Surgeons, at a joint meeting held August 29, adopted resolutions recounting the distinguished services of the late Dr. Abner Wellborn Calhoun, deploring the loss of his wise counsel, and deprivation by his death of his contributions for the public welfare, and setting apart a page in the records of the institution to be inscribed to his memory.

ILLINOIS

Personal.—Dr. Edward S. Winbigler, Alexis, is reported to be seriously ill at his home with septicemia.—Dr. Hiram T. Hardy, Kaneville, was operated on in Wesley Hospital, Chicago, August 27, for the removal of gall-stones.

1. Centralbl. f. Bakt., I, p. 107.
2. Centralbl. f. Bakt., I, 1909, I, p. 109.
3. Arb. a. d. k. Gsnqtsamte, 1910, xxiii, p. 605.

Tuberculosis Hospital in Evanston.—The Chicago Fresh Air Hospital, recently organized with Dr. Albert S. Ochsner as vice-president and Dr. Ethan A. Gray as medical superintendent, has secured a farm of 20 acres on the boundary between Chicago and Evanston with accommodations at present for 23 patients.

Notes About Hospitals.—The plans and specifications for the new hospital building for the Peoria Deaconess' Hospital are ready. The building will cost it is estimated about \$45,000. It will be of stone, 5 stories in height and fire-proof and will adjoin the present hospital building.—The hospital for the new Naval Training Station, North Chicago, which will be finished next month, is to be so arranged as to minimize noise. The nurse and emergency calls are to be made by light signals instead of buzzers or bells.

Chicago

Personal.—Dr. B. K. Shimonek has been elected director for the Central Division of the North American Esperanto Association.—Dr. and Mrs. Thos. D. Palmer have returned from Europe.

College Merger.—The American Medical Missionary College of Battle Creek and Chicago has been merged with the College of Physicians and Surgeons, Chicago, the Medical Department of the University of Illinois.

Hospital Notes.—The work of erection of the Iroquois Memorial Emergency Hospital at 87 Market Street, has been commenced, and it is expected that the relief station will be ready to receive patients about Jan. 1, 1911. The cost of the building is estimated at \$30,000. On its completion it will be turned over to the city and will be operated by the Department of Health.—The Francis E. Willard Memorial Hospital has purchased a lot 48 by 125 feet on Lincoln Street, adjoining the present hospital. The lot is improved with a two-flat building which will be remodeled and used for the nurses, and will accommodate 30. It is to be known as the Hobbs Home in honor of Mrs. J. B. Hobbs, the recording secretary. Plans for the Nelson Morris Memorial Institute of Medical Research, opposite the Michael Reese Hospital, have been completed and the work will begin in a few days. The building will be 100 by 96 feet, and four stories in height.

LOUISIANA

Hospital Buys Sanitarium.—The Presbyterian Hospital of New Orleans has acquired possession of the New Orleans Sanitarium for about \$180,000. It is proposed gradually to develop a charity department of the sanitarium under the charge of the hospital authorities.

Health Board Laboratory.—The State Board of Health will move from the Perrine Building to the new Court House Building, New Orleans, early next month. A new laboratory is being equipped in the new quarters, which will be ready for operation as soon as the change is made.

Personal.—Dr. A. Penn Crain, Shreveport, has been appointed bacteriologist and chemist of the State Board of Health, vice Dr. Jacob M. Bodenheimer.—Drs. Charles J. Landfried, Homer Dupuy, Lieven D. DePoorter, Allan A. Kennedy, John P. Leake, and A. Benjamin Gaudet have resigned from the staff of the New Orleans Eye, Ear, Nose and Throat Hospital.

MARYLAND

State Medical Society to Meet.—The Medical and Chirurgical Faculty of Maryland will hold its semi-annual meeting, September 12 to 14, at Annapolis, where extensive preparations have been made for entertainment. On the second day a symposium will be held on the administration of the State Board of Health with addresses by the various heads of the departments of that body. On the third day a joint meeting will be held with the Maryland Psychiatric Society.

Baltimore

New Building for Hospital.—The new ward building of the Bay View Hospital, which has cost \$55,000, is reported to be complete but will not be occupied until the water, heat and power plant, contracts for which have just been made, is finished.

Hospital Ship.—Dr. R. Martin Bruns has advocated a hospital ship for babies on the plan of the Boston and New York floating hospitals. He claims that with \$60,000 he can equip a ship and care for patients for two years, provid-

ing for 100 day patients and their mothers and 50 permanent patients.

Personal.—Dr. E. H. Brannon, who has had charge of a railway field hospital on the upper Amazon for two years, has returned to Baltimore. —Dr. Thomas W. Keown sailed August 31 for Ireland. —Dr. John T. King has returned from Europe. —Dr. Charles A. Fetterhoff has been appointed resident physician at St. Luke's Hospital, vice Dr. Samuel E. Edmunds, resigned. —Dr. Herbert H. Haynes, demonstrator in anatomy at the College of Physicians and Surgeons, has resigned and will practice in Clarksburg, W. Va.

MISSOURI

Tuberculosis Tour Ends.—The tuberculosis car, sent through the southwestern portion of the state by the State Society for the Relief and Control of Tuberculosis, has returned after a trip of 1,265 miles. A second trip is contemplated in September.

Aid for Sanatorium.—W. C. Root, Kansas City, consulting architect for the Missouri State Sanatorium for Incipient Tuberculosis, Mount Vernon, after careful investigation, says that the work in general has been well done at a reasonable cost, and advises the expenditure of \$35,000 for a new infirmary building.

To Save Sight of Babies.—Social settlement workers and physicians have organized the State Sight-Saving Society—the Missouri Association for the Prevention of Blindness. Dr. John Green, Jr., St. Louis, is chairman, and Drs. Clarence Loeb, Frederick J. Taussig, and Albert H. Hamell, all of St. Louis, represent the State Board of Health on the directorate. The object of the association is the awakening of the public mind to the enormous amount of preventable blindness throughout the state.

Personal.—Governor Hadley has been elected president of the Missouri Association for the Prevention and Control of Tuberculosis. —Dr. William W. Graves, St. Louis, has sailed for Europe. —Dr. Francis L. Reder, St. Louis, will sail for France this month to attend the twenty-third French Congress of Surgeons. —Dr. and Mrs. Francis R. Anthony, Maryville, sailed for Europe August 15. —Dr. Hasbrouck DeLamater has been appointed assistant to the health commissioner of Kansas City. —Dr. Elmore O. Smith, Kansas City, is said to have been fined \$100 on the charge of maintaining a private hospital for treatment of cancer without permission of the Hospital and Health Board.

NEBRASKA

Personal.—Dr. Warren W. Thompson, West Point, has been appointed assistant physician to the State Hospital for the Incurable Insane, Hastings. —Dr. William F. Callas, Omaha, has been appointed chief of the department of anatomy at Barnes University, St. Louis. —Dr. Samuel C. Beach, McCook, has been appointed a member of the board of health of Red Willow county.

State Board of Control Favored.—The state political conventions have inserted planks in their platforms endorsing the creation of a state board of control for charitable, penal and reformatory institutions. At the coming session of the legislature, an act incorporating the best features of the Iowa and Illinois laws will be introduced as a constitutional amendment. This movement has been endorsed by the county societies, the state medical society, and the Nebraska Association for Charities and Corrections.

NEW JERSEY

Cocain Dealers Sentenced.—Harry Simmons, Camden, and his wife are said to have been found guilty of the illegal sale of cocain and opium, and to have been sentenced to two years' imprisonment.

Personal.—Dr. Samuel D. Bennett has been appointed medical inspector of Millville public schools, and Dr. Duncan W. Blake, Jr. of the Gloucester City public schools. —Dr. Gustave A. Schoening and family, Trenton, have sailed for Europe.

Tuberculosis Camp for Union County.—A committee of the board of freeholders of Plainfield have recommended an administration building and four lean-tos to be built on the site of fifty acres at a cost of not to exceed \$50,000, to be raised by the issue of bonds.

NEW YORK

Personal.—The will of the late Mrs. Sarah Flower contains a bequest of \$50,000 for Dr. Murray M. Adams, Watertown. —Dr. George A. Leitner of Piermont, Dr. William Medaugh Dunning, and Dr. and Mrs. A. L. Wolbarst, New York City, have sailed for Europe.

New York City

To Enlarge Hospital.—Plans have been filed for converting the four-story private dwelling adjoining the Hospital for Deformities and Joint Diseases, New York City, into an office and dispensary, and a nurses' dormitory for the institution.

Vacancy in Dispensary.—Washington Heights Hospital Dispensary, 551 W. 165th Street, announces a vacancy in the medical and surgical department, Tuesdays, Thursdays, and Saturdays, 2 to 4 p. m. Applications should be made to Dr. Louis Neuwelt, 2424 Seventh Avenue.

Proposed Colony for Lepers.—It is understood that the Board of Health intends establishing isolation quarters for lepers on North Brother Island. There are at present four men living in a small house on Blackwell's Island who are suffering from the disease in its last stages.

Want Straus Milk Stations.—The New York Milk Committee has sent out a statement expressing regret at the announced intention of Nathan Straus to close his milk depots. The commissioner of health has also spoken very strongly on the subject. He says: "To see these milk stations shut down would be to witness a great public calamity."

Avoidance of Accidents.—The large number of street car accidents in New York City has led to the printing on the back of transfers the following warning: "Never leave a street car until it has come to a full stop. In this way you will do your share for the betterment of the service and the lessening of accidents. Most street-car accidents are due to the non-observance of this simple rule. May we look for your cooperation in this regard?"

Law Breakers.—Forty bottles of cocain are said to have been found on a man arrested in front of the police headquarters, August 22. This is said to represent the supply of cocain for Chinatown for one day. The original source of the illegal supply has not yet been traced. —William Bechtold, a former nurse in the U. S. P. H. and M.-H. Service, Stapleton, is said to have been convicted of the practice of medicine without a license, August 24, and to have been sentenced to imprisonment in Richmond County jail for thirty days.

Academy to Discuss Animal Experimentation.—The New York Academy of Medicine has purchased property at 10 W. 44th Street, and 15 W. 43rd Street, either for the purpose of remodeling the present building, or for the erection of a new building. The anniversary meeting of the academy will be held November 17, and will be devoted to animal experimentation in medicine. Addresses will be delivered by Dr. William W. Keen, Philadelphia, on "The Influence of Antivivisection on the Character of its Advocates;" by Dr. William H. Welch, Baltimore, on "The Objections to Proposals of Further Legislation to Regulate Animal Experimentation;" by Dr. W. B. Cannon, Harvard Medical School, on "The Character of Antivivisection Literature."

Buffalo

Personal.—Dr. Emil S. Tobie has been appointed a member of the board of trustees of the J. N. Adams Memorial Hospital for Incipient Tuberculosis. —Dr. David E. Wheeler arrived in Athabasca Landing, Alberta, August 30, after a sojourn of several months in the Keewatin country of the north.

Hospital for Incipient Tuberculosis.—Bids for the J. N. Adams Memorial Hospital for Incipient Tuberculosis, the new municipal hospital to be built at Perrysburg, were recently submitted at \$158,415. The trustees have decided to readvertise and double the capacity of the institution. The sum of \$200,000 is now available for construction and equipment. The site of the hospital was presented to the city by former mayor J. N. Adams. The hospital will accommodate about 300 patients.

Scarlet Fever.—Four new cases of scarlet fever have developed at Cradle Beach, the resort of the tenement children

of Buffalo, about 250 children are at this camp and conditions are believed to be so serious that the State Health Department has sent Dr. Edward Clark to investigate them. For more than two years the Buffalo Academy of Medicine and the county medical society have called the attention of the council repeatedly to the serious condition of the infectious disease situation in Buffalo, due to the fact that the facilities for the segregation of this class of patients are limited and insufficient.

NORTH CAROLINA

Visit State Tuberculosis Institutions.—The superintendent of the State Hospital for Tuberculosis, with Dr. M. Eugene Street, Glendon, R. Gordon, Greensboro, James E. Brooks, Montrose, and Richard H. Brooks, Raleigh, a committee of the directors of the institutions, are making a tour of the state tuberculosis institutions of the east.

Personal.—Dr. Thomas C. Quickel, Stanley, has located in Gastonia, where he will devote his attention to diseases of the eye, ear and throat.—Dr. Wingate Johnson, Thomasville, has located in Winston.—Dr. Alfred A. Kent, Lenoir, has received the unanimous nomination of the Democratic party of Caldwell County for representative to the legislature, and this nomination is said to be equivalent to election.

PENNSYLVANIA

Infantile Paralysis Situation.—Twenty cases of infantile paralysis were reported to the State Health Department, September 3. The disease now prevails in 41 counties, the total number of cases being at present 469.

Boards of Health Required.—It is stated that the State Commissioner of Health will send notice to all boroughs in Pennsylvania which have not organized boards of health and provided appropriation for combating disease, that they must do so without delay. This action of the commissioner will affect boroughs in every county. In case of failure to comply with this decree, the commissioner will invoke the aid of the attorney-general either by mandamus proceedings to compel the organization of board or action for revocation of charter.

Philadelphia

Personal.—Dr. Caroline M. Purnell sailed for Europe August 31.—Dr. John J. Moylan returned from Europe August 28.—Dr. Edward H. Jerecki, chief of staff at the Jewish Hospital, was badly shaken up and bruised, in a collision between his carriage and a trolley car, August 29.

Resignations from the University Faculty.—Dr. Harold B. Wood, assistant demonstrator of normal histology at the University of Pennsylvania, has resigned to become state bacteriologist and chief of the laboratories of the Mississippi State Board of Health. He will be stationed at Jackson.—Dr. Horatio C. Wood, Jr., assistant professor of pharmacology in the university, has resigned.

Special Train for State Meeting.—For those desiring to attend the annual meeting of the State Medical Society at Pittsburg, October 3 to 6, a special train will leave Broad Street Station at 10:30, Monday morning, October 3, stopping at Harrisburg, Tyrone, Altoona, Johnstown, and East Liberty. A uniform rate of two cents a mile will be charged on this train, Pullman service being extra. The train will run as the second section of the Chicago Express. Accommodation can be had by writing Dr. Albert M. Eaton, 2017 N. 13th Street, Philadelphia, Chairman of the Committee on Transportation, enclosing a stamped, directed return envelope.

Railroad Blamed for Poor Milk.—A bill of complaint against the Philadelphia and Reading Railway, in which the transportation company is held responsible for the alleged inferior grade of milk that has been supplied in certain sections of the city, was filed in Harrisburg, September 3. It is expected that the state railroad commissioners will institute a searching investigation into the manner in which railroads transport milk. The specific charge is that it required the defendant company three hours to convey the milk a distance of 35 miles in common baggage cars. Twenty thousand quarts of milk are supplied in this city daily by the Reading system.

Dedication of Consumptive Institute.—The dedication exercises of the Jewish Consumptive Institute, 406 Wharton Street, will continue for a week beginning September 11. All the Jewish organizations will be represented and addresses

will be made by the following: Dr. S. Solis-Cohen, Rabbi A. H. Erschler, Rabbi B. L. Levinthal, and Dr. M. Barbour. Dr. M. Staller is chairman of the dedication committee. In the new institution, no patients will be housed in the building, the advanced cases being turned over to sanatoriums at the expense of the institution. A dispensary will be established for incipient cases and for the distribution of milk and eggs. A large sun parlor has been constructed in the yard.

GENERAL NEWS

Electrotherapeutists to Meet.—The American Electrotherapeutic Association will hold its twentieth annual meeting at Saratoga Springs, N. Y., September 13 to 15.

Measles Epidemic in South Africa.—An epidemic of measles is reported in Pretoria. Up to the present, the inhabitants of 300 houses have been infected, and in all about 1,000 cases have been reported. The schools are being closely watched but the health officials believe that the epidemic is sufficiently under control to obviate the necessity of closing them.

Cancer Vaccine Tested.—Dr. Philip K. Gilman, formerly of Oakland, Cal., professor of surgery in the Philippine Medical School and surgeon in chief of the Philippine General Hospital, Manila, announces his belief that he has discovered a vaccine which will stop the ravages of cancer. He reports apparent cure with the vaccine in twenty cases of cancer in Manila.

Pacific Coast Surgeons Meet.—The annual meeting of the Pacific Coast Association of Railway Surgeons was held in San Francisco, August 27 and 28 and the following officers were elected: President, Dr. Oliver D. Hamlin, Oakland; vice presidents, Drs. Wallace I. Terry, San Francisco, and Robert T. Legge, McCloud, Cal.; secretary, Dr. George R. Carson, San Francisco (re-elected); treasurer, Dr. Ernest M. Keys, Alameda. The association will hold its 1911 meeting in Los Angeles, the day before the meeting of the American Medical Association.

Colored Practitioners Hold Meeting.—Colored physicians, dentists and pharmacists, making up the National Medical Association, held their meeting in Washington, D. C., August 23 to 25. Hampton Institute, Hampton, Va., was named for the next meeting-place and the following officers were elected: President, Dr. Austin M. Curtis, Washington, D. C.; vice presidents, Drs. William M. Slowe, Philadelphia, and D. L. H. Singleton, Washington, D. C.; general secretary, Dr. J. A. Kenny of the Tuskegee Institute, Ala., and member of the executive board, Dr. John W. Jones, Winston Salem, N. C.

The Valmora Sanatorium.—The Valmora Industrial Sanatorium at Watrous, New Mexico, an institution incorporated not for profit, announces that it is ready to receive patients. The expense per week for patients sent by subscribers will be \$10 and for others \$12.50. Individuals desiring to enter the sanatorium should write to the office, 34 Washington Street, Chicago, for application blanks, which should be filled out by their physicians and then presented to one of the examiners of the sanatorium who will determine whether or not the case is suitable for treatment at the institution. As the chief object is to accomplish the greatest possible good at the sanatorium, patients who have not a fair chance for recovery are not accepted. The examiners in Chicago for the institution are Dr. Arthur M. Corwin, 34 Washington Street, and Dr. Edwin B. Tuteur, 103 State Street.

Coming State and National Meetings.—A large number of state and national medical societies are to meet this fall. Among them are the following which will meet in September or October:

Amer. Acad. of Ophthalm. and Oto-Laryn., Cincinnati, Sept. 19-21.
Amer. Assn. of Obstetricians and Gynecol., Syracuse, Sept. 20-22.
Amer. Roentgen Ray Association, Detroit, September 28—October 1.
American Association of Railway Surgeons, Chicago, October 10-21.
American Electro-Therapeutic Assn., Saratoga, N. Y., Sept. 13-15.
Medical Association of the Southwest, Wichita, Kan., October 11-12.
Michigan State Medical Society, Bay City, September 28-29.
Minnesota State Medical Association, Minneapolis, October 6-7.
Mississippi Valley Medical Association, Detroit, September 13-15.
Nevada State Medical Association, Lake Tahoe, Cal., Sept. 19-21.
Pennsylvania Medical Society of State of, Pittsburg, October 3-6.
Utah State Medical Association, Salt Lake City, October 3-4.
Vermont State Medical Society, St. Albans, October 13-14.
Virginia, Medical Society of, Norfolk, October 25-28.
Wyoming State Medical Society, Casper, September 27.

MANILA LETTER

(From Our Regular Correspondent)

MANILA, P. I., July 31, 1910.

Obstetric Superstitions in the Philippines

Since so widespread an interest, both professional and lay, in the very high infant mortality in Manila and in the Philippines generally has been aroused, it is not surprising that there should follow an inquiry into the status of the practice of obstetrics and midwifery in the Islands. Such a study has been made by a number of Manila physicians interested in obstetrics. As might be expected, some interesting facts, situations and customs were encountered.

Seven articles dealing with different phases of obstetrics and gynecology are published in the *Bulletin of the Manila Medical Society* for June, 1910. It is rather surprising to learn that in both surgery and obstetrics it is particularly easy to avoid infection. The explanation of this is the rarity of the virulent streptococci. This organism is seldom encountered in laboratory work, in the morgues or in clinical work. "Streptococcic septicemia, cellulitis, erysipelas, scarlet fever and even streptococcic sore throat are extremely rare conditions in the Philippine Islands and streptococcic metritis and peritonitis following childbirth have not been encountered in autopsy work in Manila." Yet in spite of these conditions the death-rate among infants and of mothers during or following labor is very high.

In this connection it must be remembered that rational medicine is only a recent institution in the Philippines. Until the early seventies the practice of medicine was almost entirely in the hands of the quack and until very recent years the same has held true with regard to obstetrics, even among the majority of the more wealthy families. It is said that "to the Filipina woman, like the Chinese woman, personal exposure is so repulsive that often she will not accede to it even when in labor. Such scruples and shyness, caused perhaps by a misunderstanding, very often lead Filipina mothers to refuse the services of physicians and to repose their confidence in quack midwives." This is one of the principal reasons given for the almost primitive condition of obstetrical practice in the Islands. Whatever the causes of the vicious practices of the midwives, certainly the results are most lamentable and are to be seen on the streets of Manila or any of the provincial towns every day. Moreover, in Manila "the never-ending procession of women suffering from misplacements, prolapses of all degrees, lacerations of every conceivable class and severity, endometritis, fistulas, chronic congestions and inflammations, vesical troubles and general debilities is a common sight to the clinician."

It is easy to understand these conditions, as well as the fact that Filipina women become prematurely old, when one becomes aware of the obstetrical customs obtaining in the Philippines. Dr. Rebecca Parish has made a study of these customs and they are even more appalling than had been expected. Among many of the customs the following may be mentioned: If any one stands in the door in the presence of a pregnant woman, it is a sure sign that at the time of her labor the child will also stop at the door of the uterus. The prospective mother must not step over the tether of a pony while out walking as a difficult labor will result. Very tight belts and strings, worn about the waist during pregnancy, will insure an easy delivery and also prevent the child's growing too large. Many times the woman is forced to engage in the most arduous exercise, a favorite one being grinding rice; this causes an easy delivery, and is certainly effectual as the babe is sometimes born at the mill. During the course of even a normal pregnancy it is necessary for the midwife to make frequent examinations and, if she sees proper, to "change the position;" this she calls "placing the baby" and she receives 10 centavos (equal to 5 cents U. S. coin) for each such service. As a rule the Filipina woman is very indefinite as to the time when her pregnancy will terminate and consequently rarely is she prepared for this event. However, very little preparation is required except the midwife who is considered quite sufficient for her needs, and in many instances the patient cannot afford this luxury. In some provinces it is said that men act as assistants and are better for this purpose, as they are stronger and can apply more force in kneading, pressing, squeezing, pulling and pushing, as all these operations are considered essential. Short stout clubs, made of wood or burned clay and sold in the public markets, are used a great deal for pressing, pushing and kneading and are considered much more effectual for the purpose than is the hand. The waist is tied about tightly during labor to make sure that the child passes downward

instead of upward. The placenta with a paper and pen buried under the house will insure a bright and intelligent child. It is said that soup made from small pieces of the placenta and given to the mother as her first postpartum nourishment prevents fever, weakness and other forms of illness. The mother is given large quantities of rice and urged to eat so that the abdomen will be filled, as it was so large before. The waist is tied after labor to prevent the abdomen filling full of wind when the patient breathes deeply and also to prevent the blood from coming up and out of the mouth. The bones of the sacro-iliac joint are separated during labor, therefore a strong band is placed about the hips and tied tightly by two men, one bracing himself on either side with his feet against the patient's body.

The patient's abdomen is rubbed with oil for 25 days so the uterine will become soft and send out the blood, thereby becoming small. Hemorrhage is encouraged by propping the patient up with pillows—this also prevents the uterus going high in the abdomen, and causes the bad blood, which must be gotten rid of, to drain better. Frequently the patient is almost exsanguinated, and death from hemorrhage may occur without any effort being made to stop the bleeding. Sleep is not allowed because it produces a tendency to insanity; frequently the patients are allowed to sit up and even to stand within a day or two after delivery. After-pains are greatly helped by the patient getting the odor of burning deer-skin. After three days the procedure of "replacing the uterus" takes place. For 9 days it is thought bad to eat salt or drink cold water. About the tenth day the woman is bathed with a little warm water and smoked underneath a mat enclosing her and a jar of burning leaves. Following this, since there is a suspicion that the uterus is still raw, a fire is made of charcoal in a large earthen pot and the patient stands astride this, surrounded by blankets and supported by her friends. It requires an hour of this treatment to cause the uterus to "dry up." For three months the woman should not put her hand in cold water, drink cold water or take a cold bath. This rule evidently does not apply to laundresses whose occupation calls them to the river or the spring. No anti-septic precautions are known; old rags, old clothing and the family bedding are used about the parturient.

Perhaps the most prevalent and terrifying of all the superstitions is concerning the "Aswang," an imaginary being, half man and half beast. This creature prowls around at night and is the terror of the patient and all her relatives, because he watches to get the blood of the patient and to steal the child. As he lives both in the air and on the land and is guided in his night depredations by a bat, it is next to impossible to feel free from him at any time. During the latter months of pregnancy it is necessary for the woman to sleep under a black cover so that the "Aswang" cannot see her; and frequently there is a fire kept burning under the house so that the smoke may keep him away. It is considered exceedingly dangerous to be out after dark, and if the woman does go out at this time it is necessary to wear the hair loose down the back, which is her protection against the "Aswang" influencing her child and causing him also to be an "Aswang."

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Aug. 26, 1910.

Measures Adopted in France Against Cholera in Italy

The now official news of the appearance of cholera in several localities in the Italian provinces of Bari and of Foggia in the region of Apulia, where the scourge seems to have been introduced by a band of Russian pilgrims from Odessa, has naturally aroused much excitement, not only throughout Italy but also in the neighboring countries. In France, M. Briand, the prime minister, immediately telegraphed to the prefects to apply to intercourse with the infected portions of Italy the provisions of the recent decree in regard to the cholera epidemic in Russia. These provisions include surveillance over travelers at the frontier stations; isolation of persons suffering from suspected ailments; reports from hotelkeepers and others of travelers who arrived from the infected regions; reports to the mayors of every case of suspicious disease, and the designation for each department of a delegate charged with directing the application of prophylactic measures, and the prohibition of the importation of objects or products such as clothing, rags, fruits or vegetables from affected regions. All the French ports have been warned to cause all vessels coming from infected regions to undergo the measures required by the maritime sanitary police. At the moment that I write, I learn that the Swiss

orary year"—a mark of special esteem—and he died just on the eve of his final resignation. He was director of the Rothschild (Jewish) Hospital, and also head of the internal department of the General Poliklinik. In both these positions, he had gained the esteem and love of patients and students and his classes were very much frequented by foreign doctors, too. He was a recognized leader as a specialist on the diseases of the alimentary canal. His most famous books were "The Mechanical Treatment of Diseases of the Stomach and Intestines," "The Neuroses of the Stomach," "Atonia Gastrica," and a treatise on the pancreas, which is a standard work on this subject. He was a gifted and keen observer of symptoms, an exceedingly exact and scientific investigator, who did not publish much because of his long and painstaking investigations, but each of whose words stood every test. He had reached about the utmost honors a physician can attain in this country: He was imperial councillor and president of the board of health. It need not be said that his private practice was one of the best in this country.

Marriages

GEORGE BLAINE CROW, M.D., U. S. Navy, to Miss Ruth Bokenkamp, at Agana, Guam, May 26.

ALEXANDER C. FOSTER, M.D., to Miss Helen Vowells, both of Owensboro, Ky., at Louisville, August 11.

JOSEPH LINTON SILER, M.D., Philadelphia, to Miss Alice Lampe Gann of Jersey Shore, Pa., recently.

FANEUIL DUNKIN WEISSE, M.D., to Mrs. Mary Churchill Ripley, both of New York City, August 27.

COURTLAND LINDEN BOOTH, M.D., Portland, Ore., to Miss Juanita Clemm Snyder of Wheaton, Ill., August 24.

Deaths

Charles Benoni Hanson, M.D. University of Tennessee, Nashville, 1897; for six years superintendent and physician and surgeon-in-charge of the Monterey (Mexico) Hospital, an institution under the direction of the Board of Missions of the Methodist Episcopal Church, South; a member of the International Medical Association of Mexico; died in a sanitarium in San Antonio, Texas, August 10, from pellagra, aged 47.

Guy Carson Kinnaman, M.D. Rush Medical College, 1903; a member of the American Medical Association; fellow in surgery in Rush Medical College from 1903 to 1908; instructor in skin and venereal diseases in the Chicago Polyclinic, and clinical assistant and lecturer on diseases of the skin in Rush Medical College; died at the home of his parents in Ashland, Ohio, August 29, from ptomain poisoning, aged 32.

Robert Bruce Hixson, M.D. College of Physicians and Surgeons, Chicago, 1900; a member of the American Medical Association; local surgeon at Cambridge, Minn., for the Great Northern Railway; city physician of Cambridge; chairman of the local board of health, and physician of Isanti county; died at his home in Cambridge, August 23, from anterior poliomyelitis, aged 36.

Robert Amory, M.D. Harvard Medical School, 1866; of Boston; a member of the Massachusetts Medical Society; lecturer on physiology and the action of drugs in his alma mater, and later professor of physiology in Bowdoin Medical College, Brunswick, Maine; author of several works on physiology and therapeutics; died at his summer home in Nahant, Mass., August 27, aged 68.

James Meredith Mathews, M.D. Jefferson Medical College, 1840; a member of the Medical Society of the State of Pennsylvania and once president of the Berks County Medical Society; who retired from practice in 1873; for many years justice of the peace; died at his home in Reading, August 17, nine months after sustaining a fracture of the hip, aged 93.

Thomas Evans Westman Brown, M.D. College of Physicians and Surgeons, New York City, 1900; a member of the American Medical Association; of Asheville, N. C.; died suddenly from heart disease, in Memphis, Tenn., August 23, aged 37. At a special meeting of the Buncombe County Medical Society suitable resolutions and memorials were adopted.

David Gilmore Foster, M.D. Western Pennsylvania Medical College, Pittsburg, 1898; formerly of Crafton, Pa.; for three years resident physician in the West Penn. Hospital, Pittsburg; died in Campo, Cal., August 18, from the effects of a gunshot wound of the head, self-inflicted, it is believed, while despondent, on account of ill health, aged 35.

Bezaleel Bell Andrews, Jr., M.D. Marion-Sims College of Medicine, St. Louis, 1896; Kansas City-Hahnemann Medical College, 1904; formerly of Cordell, Okla., but more recently of Kansas City, Mo.; died in the Kansas City General Hospital, August 23, from the effects of phenol, self-administered, it is alleged with suicidal intent, aged 35.

William E. Miller, M.D. Ensworth Medical College, St. Joseph, Mo., 1891; formerly a member of the American Medical Association; local surgeon at Wellington, Colo., for the Colorado and Southern Railroad; died in the Fort Collins, Colo., Hospital, August 19, from septicemia, two weeks after an operation for appendicitis, aged 50.

Albert Charles Lewis, M.D. Minnesota Hospital Medical College, Minneapolis, 1882; of Mount Vernon, Wash., for several years a member of the local board of education and a member of the city council; died August 22, from heart disease, while crossing the sound from his camp on Whidby Island to the main land, aged 56.

Frank Denton Gavin, M.D. University of Maryland, Baltimore, 1874; a member of the American Medical Association; general superintendent of the Church Home and Infirmary, Baltimore, for thirty-five years; died at his home in that city, August 24, from an infection of the throat, after an illness of three months, aged 56.

William Wands, M.D. Medical College of Indiana, Indianapolis, 1880; a member of the Indiana State Medical Association; a surgeon during the Civil War; for more than 50 years a practitioner of Indianapolis, and for 8 years physician of Marion county; died at his home in Indianapolis, August 25, from heart disease, aged 73.

Albert Gallatin Sims, M.D. University of Nashville, Tenn., 1869; a member of the American Medical Association; formerly president of the Talladega County (Ala.) Medical Society, and senior councilor of the Medical Association of the State of Alabama; died at his home in Renfroe, August 8, from paralysis agitans, aged 66.

Edward Lee Pearce, M.D. University of Louisville, 1886; a member of the Kentucky State Medical Association; assistant surgeon of the Louisville Legion from 1888 to 1898; and for many years local surgeon in Louisville for the Illinois Central Railroad; died at his home, August 23, from pericarditis, aged 46.

Edwin J. Richardson, M.D. Central College of Physicians and Surgeons, Indianapolis, 1881; a veteran of the Civil War; for 23 years a special pension examiner in Washington, D. C.; and for four years deputy coroner of Marion county, Ind.; died at his home in Washington, June 23, from nephritis, aged 65.

Caleb Allen Manley, M.D. University of Nashville, 1857; surgeon in the Confederate service during the Civil War; formerly president of the Madison County (Tenn.) Board of Health, and one of the oldest practitioners of Jackson; died at his home in Jackson, August 19, from paralysis, aged 76.

Joseph Janney Hall, M.D. New York University, New York City, 1858; a member of the New York Pathological Society; and for many years consulting surgeon to the Nursery and Children's Hospital; died at his home in New York City, August 26, from arteriosclerosis and myocarditis, aged 76.

Daniel Watt Copeland, M.D. Starling Medical College, Columbus, Ohio, 1893; who served three years in the medical department of the Navy and for one year in the Army during the Spanish-American War; died at his home in Somerton, Ohio, August 23, from autointoxication, aged 40.

Stephen Milton Hand, M.D. Berkshire Medical College, Pittsfield, Mass., 1853; for twenty years health officer of Norwich, N. Y.; and at one time president of the Chenango County Medical Society; died suddenly August 9, from heart disease while making a professional call, aged 79.

Foster Frutchey, M.D. Medico-Chirurgical College of Philadelphia, 1891; a member of the Illinois State Medical Society; professor of operative surgery and applied anatomy in Illinois Medical College; died at his home in Chicago, August 28, from meningitis, aged 44.

Joseph Merritt Moore, M.D. Eclectic Medical College of the city of New York, 1881; a veteran of the Civil War; once

president of the state eclectic medical society; died at his home in West Rupert, Vt., August 17, from valvular heart disease, aged 74.

James E. Taylor, M.D. Cincinnati College of Medicine and Surgery, 1871; of Richmond, Ind.; a veteran of the Civil War; a practitioner for more than 50 years; died in a sanitarium in Spiceland, Ind., August 25, from heart disease, aged 75.

Henry Francis Murray, M.D. Tulane University of Louisiana, 1851; a veteran of the Mexican War; for 60 years a resident of the Choctaw and Chickasaw nations; died at the home of his son near Colbert, Okla., Dec. 29, 1909, aged 91.

Samuel Scott Salisbury, M.D. Western Reserve University, Cleveland, 1854; a member of the Illinois State Medical Society; for nearly half a century a practitioner of Tolono, Ill.; died at his home, August 22, from senile debility, aged 81.

Henry M. Pollard, M.D. Missouri Medical College, St. Louis, 1888; a member of the American Medical Association; for more than 20 years a practitioner of Shelbyville, Mo.; died in Kansas City, Mo., August 21, from myocarditis, aged 49.

Martha A. Richardson, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1896; of Canton, Ill.; a member of the American Medical Association; died in the Proctor Hospital, Peoria, Ill., August 25, from chronic nephritis, aged 39.

Paul Cheesebrough Skiff, M.D. Yale University, New Haven, 1853; of New Haven; a practitioner of New Haven for more than 40 years; died at his summer home in Kent, Conn., August 26, from cerebral hemorrhage, aged 81.

Robert W. Park, M.D. University of Pennsylvania, 1856; surgeon of the Fifth Alabama Infantry, C. S. A. during the Civil War; and for nearly 40 years a practitioner of Waco, Texas; died at his home, August 21, aged 74.

Oscar W. Oberlander, M.D. Syracuse (N. Y.) University, 1881; a member of the Medical Society of the State of New York and the Syracuse Academy of Medicine; died in Ogdensburg, N. Y., June 25, from general paresis.

Harland L. Stanbro, M.D. University of Buffalo, 1896; died at his home in Prattsburg, N. Y., August 9, from burns caused by the explosion of the gasoline tank of an automobile a week before in Wayland, aged 39.

William B. Presnell, M.D. Barnes Medical College, St. Louis, 1901; of Center, Okla.; died in that place, August 29, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent, aged 39.

Darwin G. Palmer, M.D. Western Reserve University, Cleveland, 1879; a veteran of the Civil War; a member of the American Medical Association; died at his home in Geneva, Ohio, August 27, aged 68.

Joseph J. Tremblay, M.D. College of Physicians and Surgeons, Chicago, 1895; a member of the American Medical Association; died suddenly at his home in Moline, Ill., August 23, from heart disease, aged 48.

David Howard Cronyn, M.D. Long Island College Hospital, Brooklyn, 1873; a veteran of the Civil War; coroner of Brown county, S. D.; died at his home near Houghton, August 21, from arteriosclerosis, aged 66.

Joseph Dennis Willson, M.D. Cooper Medical College, San Francisco, 1873; for more than 50 years a practitioner of California; died at his home in Cloyne Court, Berkeley, August 25, from nephritis, aged 80.

William Becker Stewart, M.D. University of Vermont, Burlington, 1904; formerly a member of the Vermont State Medical Society; died at his home in Unadilla, N. Y., August 21, from nephritis, aged 32.

Kimmel K. Harrison, M.D. Eclectic Medical Institute, Cincinnati, 1872; of Clayton, Mich.; died near his home in that place, August 24, from the effects of the kick of a horse, aged 75.

William H. C. Sterrett, M.D. Missouri Medical College, St. Louis, 1891; formerly of Corning, Mo.; died in Excelsior Springs, Mo., July 28, from the effects of a fall down stairs, aged 40.

Julius Stein, M.D. College of Physicians and Surgeons, New York City, 1885; died at his home in New York City, July 22, from fatty degeneration of the heart, aged 47.

Jacob Alexander Baker, M.D. Meharry Medical College, Nashville, 1903; formerly of Jacksonville, Fla.; died in Asheville, N. C., August 16, from tuberculosis, aged 33.

Nicholas Blackwell, M.D. Jefferson Medical College, 1860; surgeon in the Confederate service during the Civil War; died at his home in Bartlett, Tenn., August 16, aged 71.

Louis Phillippe Coyner (Years of practice, Va.) For twenty years a practitioner of Spring Creek; died at his home in Waynesboro, August 11, from diarrhea, aged 62.

Francis M. Carez, M.D. Paris, France; a veteran of the Mexican and Civil wars; died at his home in Fort Scott, Kan., July 9, from senile debility, aged 91.

Wilson Lumpkin Heflin, M.D. Medical College of Georgia, Augusta, 1851; died at his home in Roanoke, Ala., August 13, from cerebral hemorrhage, aged 82.

Isaac N. English, (license, Minn., 1896); for many years a practitioner of Motley; died in Brainerd, August 26, from carcinoma of the stomach, aged 59.

John Jacob Strecker, M.D. Columbus (Ohio) Medical College, 1880; died at the home of his son in Chattanooga, Tenn., August 6, from diabetes, aged 79.

William C. Stout, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1871; died at his home in Killbuck, Ohio, August 19, from paralysis.

Frederick Densmore Tyrrell, M.D. Bellevue Hospital Medical College, 1895; died at his home in Sacramento, Cal., August 5, from uremia, aged 39.

Robert Emery, M.D. Victoria College, Toronto, 1857; one of the oldest practitioners of Peoria, Ill.; died suddenly in Dunlap, Ill., August 24, aged 82.

Douglas C. Cannon, M.D. Bellevue Hospital Medical College, 1866; a Confederate veteran; died at his home in Norfolk, Va., August 21, aged 74.

Alfonso Wetmore, M.D. New York University, New York City, 1848; died at his home in Clinton, Iowa, August 24, from senile debility, aged 89.

Charles B. West, M.D. Jefferson Medical College, 1883; died suddenly at his home in Upper Strasburg, Pa., August 18, from heart disease, aged 52.

Hannah Tyler Wilcox, M.D. Homeopathic Medical College of Missouri, St. Louis, 1884; died at her home in St. Louis, Nov. 22, 1909, aged 71.

Otis A. Jakway, M.D. University of Buffalo, 1875; a veteran of the Civil War; died at his home in Breesport, N. Y., August 14, aged 76.

William Fleet Nelson, for 33 years a practitioner of Clay county, Mo.; died at his home in Liberty, Dec. 26, 1909, from rheumatism, aged 60.

William W. Easton, M.D. Bennett Medical College, Chicago, 1877; died at his home in Dowagiac, Mich., July 14, from paralysis, aged 56.

Chalon Guard Campbell, M.D. Washington University, St. Louis, 1875; died at his home in San Bernardino, Cal., August 22, aged 61.

Pharmacology

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION]

CAPTOL

W. A. Puckner and L. E. Warren

"Captol" is a hair tonic put on the American market by Mülhens & Kropff, New York City under the following claims:

"Captol is a newly invented chemical product of the Chemical Works, late Fr. Bayer & Co., Elberfeld."

"... the outcome of the joint condensation of tannin and chloral and possessing neither the unpleasant secondary effects of tannin nor the particular irritating action so frequently observed in the employment of chloral."

"The unrivalled hair tonic."

"A preventive of baldness."

"Contains: Not to exceed 70 per cent. alcohol, 4 grains chloral hydrate to the ounce, 3 grains Captol pure to the ounce."

Since, according to the circular, "Captol" is a condensation product of chloral and tannin the term "Captol" is evidently used by the manufacturer in two senses, viz., one intended to refer to the alleged chloral-tannin "synthetic" and the other meaning a solution of the "synthetic," together with other ingredients, in alcohol.

Several formulas for "Captol" hair tonics are found in pharmaceutical literature. As they are all similar, the fol-

orary year"—a mark of special esteem—and he died just on the eve of his final resignation. He was director of the Rothschild (Jewish) Hospital, and also head of the internal department of the General Poliklinik. In both these positions, he had gained the esteem and love of patients and students and his classes were very much frequented by foreign doctors, too. He was a recognized leader as a specialist on the diseases of the alimentary canal. His most famous books were "The Mechanical Treatment of Diseases of the Stomach and Intestines," "The Neuroses of the Stomach," "Atonia Gastrica" and a treatise on the pancreas, which is a standard work on this subject. He was a gifted and keen observer of symptoms, an exceedingly exact and scientific investigator, who did not publish much because of his long and painstaking investigations, but each of whose words stood every test. He had reached about the utmost honors a physician can attain in this country: He was imperial councillor and president of the board of health. It need not be said that his private practice was one of the best in this country.

Marriages

GEORGE BLAINE CROW, M.D., U. S. Navy, to Miss Ruth Bokenkamp, at Agana, Guam, May 26.

ALEXANDER C. FOSTER, M.D., to Miss Helen Vowells, both of Owensboro, Ky., at Louisville, August 11.

JOSEPH LINTON SINEE, M.D., Philadelphia, to Miss Alice Lampe Gann of Jersey Shore, Pa., recently.

FANEUIL DUNKIN WEISSE, M.D., to Mrs. Mary Churchill Ripley, both of New York City, August 27.

COURTLAND LINDEN BOOTH, M.D., Portland, Ore., to Miss Juanita Clemm Snyder of Wheaton, Ill., August 24.

Deaths

Charles Benoni Hanson, M.D. University of Tennessee, Nashville, 1897; for six years superintendent and physician and surgeon-in-charge of the Monterey (Mexico) Hospital, an institution under the direction of the Board of Missions of the Methodist Episcopal Church, South; a member of the International Medical Association of Mexico; died in a sanitarium in San Antonio, Texas, August 10, from pellagra, aged 47.

Guy Carson Kinnaman, M.D. Rush Medical College, 1903; a member of the American Medical Association; fellow in surgery in Rush Medical College from 1903 to 1908; instructor in skin and venereal diseases in the Chicago Polyclinic, and clinical assistant and lecturer on diseases of the skin in Rush Medical College; died at the home of his parents in Ashland, Ohio, August 29, from ptomain poisoning, aged 32.

Robert Bruce Hixson, M.D. College of Physicians and Surgeons, Chicago, 1900; a member of the American Medical Association; local surgeon at Cambridge, Minn., for the Great Northern Railway; city physician of Cambridge; chairman of the local board of health, and physician of Isanti county; died at his home in Cambridge, August 23, from anterior poliomyelitis, aged 36.

Robert Amory, M.D. Harvard Medical School, 1866; of Boston; a member of the Massachusetts Medical Society; lecturer on physiology and the action of drugs in his alma mater, and later professor of physiology in Bowdoin Medical College, Brunswick, Maine; author of several works on physiology and therapeutics; died at his summer home in Nahant, Mass., August 27, aged 68.

James Meredith Mathews, M.D. Jefferson Medical College, 1840; a member of the Medical Society of the State of Pennsylvania and once president of the Berks County Medical Society; who retired from practice in 1873; for many years justice of the peace; died at his home in Reading, August 17, nine months after sustaining a fracture of the hip, aged 93.

Thomas Evans Westman Brown, M.D. College of Physicians and Surgeons, New York City, 1900; a member of the American Medical Association; of Asheville, N. C.; died suddenly from heart disease, in Memphis, Tenn.; August 23, aged 37. At a special meeting of the Buncombe County Medical Society suitable resolutions and memorials were adopted.

David Gilmore Foster, M.D. Western Pennsylvania Medical College, Pittsburg, 1898; formerly of Crafton, Pa.; for three years resident physician in the West Penn. Hospital, Pittsburg; died in Campo, Cal., August 18, from the effects of a gunshot wound of the head, self-inflicted, it is believed, while despondent, on account of ill health, aged 35.

Bezaleel Bell Andrews, Jr., M.D. Marion-Sims College of Medicine, St. Louis, 1896; Kansas City-Hahnemann Medical College, 1904; formerly of Cordell, Okla., but more recently of Kansas City, Mo.; died in the Kansas City General Hospital, August 23, from the effects of phenol, self-administered, it is alleged with suicidal intent, aged 35.

William E. Miller, M.D. Ensworth Medical College, St. Joseph, Mo., 1891; formerly a member of the American Medical Association; local surgeon at Wellington, Colo., for the Colorado and Southern Railroad; died in the Fort Collins, Colo., Hospital, August 19, from septicemia, two weeks after an operation for appendicitis, aged 50.

Albert Charles Lewis, M.D. Minnesota Hospital Medical College, Minneapolis, 1882; of Mount Vernon, Wash., for several years a member of the local board of education and a member of the city council; died August 22, from heart disease, while crossing the sound from his camp on Whidby Island to the main land, aged 56.

Frank Denton Gavin, M.D. University of Maryland, Baltimore, 1874; a member of the American Medical Association; general superintendent of the Church Home and Infirmary, Baltimore, for thirty-five years; died at his home in that city, August 24, from an infection of the throat, after an illness of three months, aged 56.

William Wands, M.D. Medical College of Indiana, Indianapolis, 1880; a member of the Indiana State Medical Association; a surgeon during the Civil War; for more than 50 years a practitioner of Indianapolis, and for 8 years physician of Marion county; died at his home in Indianapolis, August 25, from heart disease, aged 73.

Albert Gallatin Sims, M.D. University of Nashville, Tenn., 1869; a member of the American Medical Association; formerly president of the Talladega County (Ala.) Medical Society, and senior counselor of the Medical Association of the State of Alabama; died at his home in Renfroe, August 8, from paralysis agitans, aged 66.

Edward Lee Pearce, M.D. University of Louisville, 1886; a member of the Kentucky State Medical Association; assistant surgeon of the Louisville Legion from 1888 to 1893; and for many years local surgeon in Louisville for the Illinois Central Railroad; died at his home, August 23, from pericarditis, aged 46.

Edwin J. Richardson, M.D. Central College of Physicians and Surgeons, Indianapolis, 1881; a veteran of the Civil War; for 23 years a special pension examiner in Washington, D. C.; and for four years deputy coroner of Marion county, Ind.; died at his home in Washington, June 23, from nephritis, aged 65.

Caleb Allen Manley, M.D. University of Nashville, 1857; surgeon in the Confederate service during the Civil War; formerly president of the Madison County (Tenn.) Board of Health, and one of the oldest practitioners of Jackson; died at his home in Jackson, August 19, from paralysis, aged 76.

Joseph Janney Hall, M.D. New York University, New York City, 1858; a member of the New York Pathological Society; and for many years consulting surgeon to the Nursery and Children's Hospital; died at his home in New York City, August 26, from arteriosclerosis and myocarditis, aged 76.

Daniel Watt Copeland, M.D. Starling Medical College, Columbus, Ohio, 1893; who served three years in the medical department of the Navy and for one year in the Army during the Spanish-American War; died at his home in Somerton, Ohio, August 23, from autointoxication, aged 40.

Stephen Milton Hand, M.D. Berkshire Medical College, Pittsfield, Mass., 1853; for twenty years health officer of Norwich, N. Y.; and at one time president of the Chenango County Medical Society; died suddenly August 9, from heart disease while making a professional call, aged 79.

Foster Frutchey, M.D. Medico-Chirurgical College of Philadelphia, 1891; a member of the Illinois State Medical Society; professor of operative surgery and applied anatomy in Illinois Medical College; died at his home in Chicago, August 28, from meningitis, aged 44.

Joseph Merritt Moore, M.D. Eclectic Medical College of the city of New York, 1881; a veteran of the Civil War; once

PRONUNCIATION OF "DIPHTHERIA"

To the Editor:—What is the correct pronunciation of diphtheria. Is it *diff-theria* or *dip-theria*? F. E. S.

ANSWER.—Most authorities prefer the pronunciation *diff-theria*. *Dip-theria* is given as a second choice by several dictionaries: Century, Stormonth and Webster. The word is derived from the Greek *diphthera* (δίφθερα), a membrane; so that the pronunciation corresponds to the terminology.

PREPARATION OF SECTIONS FOR THE MICROSCOPE

To the Editor:—Please refer me to a late work on the preparation of specimens for the microtome and the technique for staining sections in pathologic work? V. L. MASS, Melrose, Mass.

ANSWER.—Mallory and Wright: *Pathologic Technique*, W. B. Saunders Co., Philadelphia. Lee: *The Microtome and its Vade-Mecum*, P. Blakiston's Son & Co., Philadelphia.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Aug. 27, 1910:

Norris, H. C. R., M. R. C., relieved from duty at Vancouver Barracks, Wash., and will proceed to his home, and on arrival there report by telegraph to the Adjutant General of the Army for further orders.

Sanford, Joseph L., M. R. C., granted 30 days' leave of absence. Hill, Felix R., Lieut., left Fort George Wright, Wash., en route to Wallace, Idaho, on detached duty.

Graham, George D., D. S., left Fort Leavenworth, Kan., on 10 days' leave of absence.

Maul, Louis M., col., will proceed from Chicago, to Fort Benjamin Harrison, Ind., for duty at Camp of Instruction.

Hall, James F., capt., in addition to his other duties, will take charge of the office of the chief surgeon, Dept. of the Lakes, Chicago.

Persons, Elbert E., major, will, at the proper time, join the 11th and 18th Cos. Coast Artillery in New York City, and proceed with those organizations to San Francisco, and on completion of this duty return to station. Major Persons is authorized to delay one month en route on returning.

Hess, Louis T., major, will proceed, at the proper time, to Fort Mott, N. J., for duty with the 42nd and 138th Cos. Coast Artillery, en route to San Francisco. Major Hess is authorized to delay 10 days en route in returning.

Reasoner, M. W., capt., left camp, American Lake, Wash., en route to Butte Falls, Ore., with troops to fight fire.

Griswold, W. Church, M. R. C., relieved from duty at Fort Oglethorpe, Ga., Oct. 1, 1910, and will proceed to Brooklyn, reporting on arrival to the Adjutant General of the Army. Lieutenant Griswold is relieved from active duty in the M. R. C., to take effect on the expiration of leave of absence granted him this date for 1 month and 15 days, to take effect on arrival at Brooklyn.

Manly, C. L., major, granted leave of absence for 2 months.

McIntyre, H. B., capt., relieved from duty at Army General Hospital, San Francisco, and ordered to Fort Caswell, N. C., for duty.

Sanford, Joseph L., M. R. C., relieved from duty at Fort Caswell, N. C., and ordered to Fort Ruger, H. T., for duty.

Hopwood, L. L., capt., relieved from duty at Army General Hospital, San Francisco, and ordered to Fort Monroe, Va., for duty.

Bartlett, Wm. K., capt., relieved from duty at Fort Totten, N. Y., and ordered to the Philippines Division for duty on transport sailing from San Francisco, Nov. 3, 1910.

Hefsehower, Roy C., Lieut., relieved from duty at Army Medical School, and ordered to Fort Hamilton, N. Y., for duty.

Gentry, Ernest R.; Thearle, Wm. H., Lieuts., relieved from duty at the Army Medical School and ordered to Fort Leavenworth, Kan., for duty.

Cooper, Alexander F., Lieut., relieved from duty at Army Medical School, and ordered to proceed to San Francisco, for assignment to duty at Army General Hospital, San Francisco.

Risdon, Herbert T., D. S., recently appointed, will proceed from San Francisco, to Fort Riley, Cal., for temporary duty.

Woodson, Thomas D., Lieut., reports arrival at Republic Wash., with Cos. B and C, 1st Inf., on detached service, left Camp, American Lake, Wash., Aug. 13, 1910.

Marshall, John S., E. D. S., admitted to Army General Hospital, San Francisco, for observation and treatment.

Patterson, R. F., D. S., left Fort Sheridan, Ill., en route to Fort Benjamin Harrison, Ind., on temporary duty.

Keller, William L., capt., left West Point, N. Y., with cadets on practice march.

Banister, William B., Lieut. col., left Camp Bruce E. McCoy, Sparta, Wis., on leave of absence.

Jenkins, F. E., M. R. C., left Camp of Instruction, Fort Riley, Kan., on leave of absence.

Bally, Howard H., capt., ordered to proceed to Fort Ancient, Ohio, for duty as inspector-instructor of the First Ohio Brigade Encampment, from Aug. 27 to Sept. 4, 1910.

Thearle, Wm. H., Lieut., granted 10 days' leave of absence about Sept. 1, 1910.

Crum, Wayne H., Lieut., ordered to accompany Co. A, Signal Corps, to Fort Benjamin Harrison, Ind., for duty at Camp of Instruction.

Bursey, Charles N., major, will report in person without delay to Brigadier General Wm. P. Hall, adjutant general, president Army Retraining Board, at Washington, D. C., for examination by the board.

Baker, David, major, leave of absence extended 20 days.

Bowman, M. H., M. R. C., ordered to Presidio of San Francisco, for temporary duty.

Flerson, Robert H., capt., left Vancouver Barracks, Wash., on detached duty, en route to Butte Falls, Ore.

Lynch, Edward C., M. R. C., reports for duty at Fort D. A. Russell, Wyo., Target and Maneuver Reservation, Wyo.

DeWitt, Wallace, major, left Fort Yellowstone, Wyo., on practice march with Troop E, 5th Cavalry.

Bisdon, H. T., D. S., reported for duty at Fort Riley, Cal.

Heterlek, R. H., M. R. C., left Fort Oglethorpe, Ga., en route to Key West, Barracks, Fla., on detached duty.

Changes for the week ended Sept. 3, 1910:

Hallett, Harley J., M. R. C., ordered to proceed to Fort Hamilton, N. Y., Aug. 29, for temporary duty.

Hill, Eben C., Lieut., ordered to proceed to Pine Camp, N. Y., for duty.

Matletta, S. U., M. R. C., left Fort Des Moines, Iowa, en route to Camp at Fort Benjamin Harrison, Ind.

Baker, Frank C., major, left Fort Moultrie, S. C., en route to Camp at Fort Benjamin Harrison, Ind.

O'Connor, R. P., major, left Fort Screven, Ga., en route to Camp at Fort Benjamin Harrison, Ind.

Shaw, Henry A., major, granted 20 days' leave of absence.

Nichols, Henry J., Lieut., on expiration of present leave of absence, will repair from duty in New York City to this city and report in person to Colonel Louis A. LaGarde, Medical Corps, president of the Army Medical School, for duty as assistant instructor in clinical microscopy and bacteriology at that school.

Wolfe, Edwin P., major, ordered to proceed from New York City to Philadelphia, on business connected with the Medical Department of the Army. Major Wolfe will also proceed from New York City to Middletown, Conn., on business connected with the Medical Department of the Army.

Howell, Park, capt., granted leave of absence for 2 months.

Norman, Seaton, M. R. C., ordered to proceed to Fort Huachuca, Ariz., for temporary duty.

Darnall, M. H., M. R. C., left Fort Washington, Md., on 10 days' leave of absence.

Long, Charles J., D. S., granted 2 months' leave of absence.

Kieruff, H. Newton, M. R. C., relieved from duty at Fort Missoula, Mont., and ordered to proceed to his home for further orders. Same date granted leave of absence for 1 month and 4 days.

Birmingham, Henry P., Lieut.-col., leave of absence extended 20 days.

Mabee, James I., capt., left Jefferson Barracks, Mo., on 8 days' leave of absence.

Long, Charles J., D. S., reports for temporary duty at Madison Barracks, N. Y., from Pine Camp, N. Y.

McGaw, W. D., Lieut.-col., left Washington, D. C., on 30 days' leave of absence.

Irland, M. W., major, left Washington, D. C., on 18 days' leave of absence.

Lynch, Charles, major; Bally, Howard H., capt., and DeLaney, M. A., capt., detailed to act as judges of the Inter-Coal Co. competition in the application of first aid to the injured, to be held Sept. 17, 1910, at Scranton, Pa.

Bundesen, H. N., M. R. C., granted 15 days' leave of absence.

LaGarde, Louis A., col.; McGaw, Walter D., Lieut.-col., and Winter, Francis A., major, appointed members of a board to meet in this city, Sept. 20, 1910, for the examination of such applicants for appointment in the Medical Corps as may be invited to appear before the board.

Talbot, E. M., capt., on return to Fort D. A. Russell, Wyo., will proceed to Fort Riley, Kan., for duty at camp of instruction in command of one-half of Co. A, Hospital Corps.

Tenney, Elmer S., M. R. C., relieved from duty at Fort Strong, Mass., and ordered to proceed to the Philippine Islands for duty on the transport sailing from San Francisco about Nov. 5, 1910.

Slater, Ernest F., M. R. C., granted 30 days' leave of absence.

Medical Corps, U. S. Navy

Changes for the week ended Aug. 27, 1910:

Fitts, H. B., medical inspector, ordered to the Naval Medical School Hospital, Washington, D. C., for treatment.

Downey, J. O., P. A. surgeon, commissioned passed assistant surgeon from Aug. 1, 1909.

Stratton, R. J., P. A. surgeon, commissioned passed assistant surgeon from Dec. 20, 1909.

Stendman, W. G., Jr.; Donelson, M., and Baker, M. C., P. A. surgeons, commissioned passed assistant surgeons from July 12, 1910.

Lays, J. F., surgeon, ordered to temporary duty in the bureau of medicine and surgery, Navy Department.

Higgins, M. E., asst.-surgeon, ordered to temporary duty at the Naval Medical School Hospital, Washington, D. C.

Dodge, A. H., asst.-surgeon, granted sick leave for 3 months when discharged from treatment at the Naval Hospital, Mare Island, Cal.

Cohn, I. F., P. A. surgeon, commissioned passed assistant surgeon from Feb. 28, 1910.

Fitts, H. B., medical inspector, ordered home to wait orders, when discharged from treatment at the naval medical hospital school, Washington, D. C.

Richardson, R. R., surgeon, ordered to duty at the Navy Yard, Portsmouth, N. H., and to additional duty in connection with the Southern, the Topeka, and the Naval Hospital at that place.

Valz, E. V., P. A. surgeon, detached from duty at the Navy Yard, Portsmouth, N. H., and ordered to duty at the Naval Prison at that place.

Iden, J. H., surgeon, commissioned surgeon from Oct. 31, 1909.

Seaman, W., surgeon, commissioned surgeon from Nov. 20, 1909.

Richardson, R. R., surgeon, commissioned surgeon, from Dec. 13, 1909.

Asserson, F. A., surgeon, commissioned surgeon, from Jan. 30, 1910.

Dunn, H. A., surgeon, commissioned surgeon from Feb. 5, 1910.

Stuart, A., surgeon, commissioned surgeon from Feb. 19, 1910.

Step, J., surgeon, commissioned surgeon from March 5, 1910.

Lee, A. E., P. A. surgeon, commissioned passed assistant surgeon from May 9, 1909.

The following named acting assistant surgeons are detached from duty at the places indicated and ordered to Washington, D. C., for examination for appointment as assistant surgeons: O. J. Miller,

changes take place in the blood during respiration? Where and how is it accomplished? 7. In a general way, of what does digestion consist? 8. What are enzymes and how do they act? 9. What is the function of the pancreatic juice? 10. What are the solid constituents of the urine and what conditions may change their quantity in health?

MATERIA MEDICA AND THERAPEUTICS (REGULAR)

1. Explain the action of heat and cold as therapeutic agents and mention indications for each. 2. Under what conditions would you advise arterial transfusion of blood? What advantage has the process over hypodermoclysis? What disadvantage? 3. Given a case of diphtheria in a child five years old. Describe in detail your treatment and the effect expected of the remedy. 4. When should silver nitrate and when should the organic salts of silver be used in the treatment of ophthalmia neonatorum? 5. Give some indications for the use of thyroid gland. What untoward effects are produced by over use? 6. Give some indications for the use of arsenic. In what forms may it be used? Give dose of each and symptoms resulting from its excessive use. 7. Outline a diet for a patient suffering with diabetes mellitus. Also for one suffering with chronic interstitial nephritis. 8. What would you use to overcome pleurisy with effusion? Explain action. 9. Explain the physiologic action of the salines. 10. For what conditions would you advise x-ray treatment? How long should the patient be exposed at a single sitting? When would you advise him to return for treatment if a series of treatments were advised?

MATERIA MEDICA AND THERAPEUTICS (HOMEOPATHIC)

1. Explain the action of heat and cold as therapeutic agents and mention indications for each. 2. Name the salient symptoms that would lead you to prescribe opium. In what doses would you prescribe it? Is a careful history of the case essential? How many alkaloids has opium? Name five. 3. In prescribing—what is the only true scientific basis for the selection of a drug? 4. Given—swelling and suppuration of glands; exostosis, curvature, caries, pale blotted face, ulceration of skin, swelling of nose and upper lip, scabs on hairy scalp, otorrhea—cancerous affection. Prescribe. 5. Give some indications for the use of thyroid gland. What untoward effects are produced by over use? 6. Diagnose dysentery and give the three most likely indicated remedies. 7. Given—a woman extremely pale, not emaciated, pulse rapid, 160, almost imperceptible at wrist, slow of comprehension, difficult respiration, coldness of extremities, finger nails blue, excessive hemorrhage from uterus, history of pregnancy negative, single—give the homeopathically indicated remedy. What would you do? 8. How would you treat a case of membranous croup? What germ is present? Name three remedial agencies that will probably be indicated during progress? 9. Differentiate calcarea carb and silicea. Rhus tox and lachesis. 10. For what conditions would you advise x-ray treatment? How long should the patient be exposed at a single sitting? When would you advise him to return for treatment if a series of treatments were advised?

MATERIA MEDICA AND THERAPEUTICS (ECLECTIC)

1. Explain the action of heat and cold as therapeutic agents and mention indications for each. 2. In what class of agents would you place passiflora? How would you prescribe it? What indications would guide you? 3. What are the properties of gelsemium? What are its indications and in what diseases is it useful? 4. Give dose and indications for use of apocynum. Name some conditions in which you would prescribe it. 5. Give some indications for the use of thyroid gland. What untoward effects are produced by over use? 6. Give indications for bryonia and diseases in which it is useful. 7. What uses would you make of phenol (carbolic acid) in practice? How use it? 8. Chionanthus—In what conditions is this agent useful? What are indications for it? 9. What is the formula of Dover's powder? What are its properties and uses? 10. For what conditions would you advise x-ray treatment? How long should the patient be exposed at a single sitting? When would you advise him to return for treatment if a series of treatments were advised?

Pennsylvania June Reports

The Medical Council of Pennsylvania reports the written examinations held at Philadelphia, Pittsburg and Harrisburg, June 21-24, 1910. The number of subjects examined in was 7; percentage required to pass, 75.

At the examination held by the State Medical Society of Pennsylvania, the total number of candidates examined was 347, of whom 308 passed and 39 failed. The following colleges were represented:

College.	PASSED.	Year.	Total No. Examined.
Illinois Medical College		(1909)	1
Rollance Medical College		(1909)	1
Chicago College of Medicine and Surgery		(1910)	4

Medicolegal

Privilege and Waiver of Same Extend to Statements Made by Physicians.

The Supreme Court of Nebraska says, in Bryant vs. Modern Woodmen of America (125 N. W. R., 621), that the insured in his application waived for himself and his beneficiaries "the privilege or benefits of any and all laws which are now or may be hereafter in force making incompetent the testimony of or disqualifying any physician from testifying concerning any information obtained by him in a professional capacity." When, however, the testimony of a physician who had previously amputated the man's arm above the wrist was offered to show that he told the man at that time that he was suffering from tuberculosis of the wrist, the evidence was excluded on the ground that the communication from the physician to the patient was a privileged one, and had not been waived. But holding that it had not been waived was error.

A statement of fact or opinion expressed by a physician to a patient in the course of a professional visit, based on a

relation of facts by the patient, or on a physical examination by the physician, is as much a privileged communication as the facts or statements on which it is based. It is a part of the same transaction, and, if the statute excludes the facts disclosed by the patient, it must equally exclude the statements and the opinions, expressed or unexpressed, of the physician, if its protection is to be of any avail. If the physician is permitted to disclose what he said to the patient, the patient's privilege to prevent the disclosure of a communication by him to the physician or the result of an examination would be of little use; for by indirection a disclosure of the nature of the disease would in many instances be made.

A waiver of the privilege or benefit of the protecting statute is a waiver of the disqualification as to the whole transaction, and not as to a part of it only. And, in view of the statements in the application, if the evidence should prove that the insured had consulted reputable physicians as to his condition, and that he had been told by them that he was suffering from such an insidious and dangerous disease as tuberculosis at a time so near the time of making the application as to rebut and repel the idea of forgetfulness or good faith on his part, the concealment of such a fact, so material to the risk, and one that if known his application would have been rejected, would render void the contract. The offered evidence would tend to show notice and knowledge by the applicant of the actual facts as to his condition before he made the representations in his application. It was material to the issues, and since the privilege was waived, was admissible.

Limit to Responsibility of Employer Selecting Surgeon—Skill and Learning Required—Sufficiency of Fluoroscopic X-Ray Examination Without Making Photograph

The Supreme Court of Washington holds, in *Wells vs. Ferry-Baker Lumber Co.* (107 Pac. R. 869), that where an employer withholds \$1 per month from the wages of its employees, and pays same to a physician or surgeon selected by it, the implied duty of the employer is to select a competent physician and surgeon, and when it does so it discharges its full legal obligation. There being no express contract between the employer and its employees, and no profit resulting to the employer, it is a noncompensated or gratuitous trustee, and is liable only for a failure to use reasonable care in the selection of a competent surgeon.

A physician and surgeon by taking charge of a case impliedly represents that he possesses, and the law imposes on him the duty of possessing, reasonable skill and learning. He is not liable for mistakes if he uses the method recognized and approved by those reasonably skilled in the profession.

The plaintiff in this case, an employee of the defendant company, had a fall in which the bones of each wrist were broken, but alleged that the surgeon selected by the company negligently treated the left one for a sprain. The evidence disclosed that the surgeon at first expressed the opinion that both arms were broken, but said that he would examine them with the x-ray; that he did so, and then said that there was a fracture of the right wrist, but that the left was sprained; that he so treated them; that the right wrist was restored to its normal condition; that, on complaint from time to time that the left wrist was painful and not improving, he re-examined it with the x-ray at least three times; that each examination confirmed his later opinion that it was sprained and not broken; that he said to the plaintiff whenever he complained of the pain that a sprain was "worse" than a break. The x-ray examinations were what were termed "fluoroscopic," to make which, as it was explained, "You use an x-ray, but instead of taking a picture you have an apparatus that you hold in the hand and look through the arm." The only negligence claimed was that the attending surgeon failed to take an x-ray photograph so as to make certain his diagnosis.

The conclusion, the Supreme Court says, is irresistible, that the surgeon used reasonable diligence and skill, and that to permit a recovery of damages would establish the rule that

a surgeon is liable for a failure to use extraordinary care and diligence in both diagnosis and treatment. The surgeon who testified that an x-ray photograph should have been taken stated that he had practiced his profession for a period of 20 years, and that he had never had an x-ray machine. He examined the plaintiff for the first time about 17 months after the injury, and took x-ray photographs of the left wrist which he said showed a fracture which in his opinion a like investigation in the beginning would have revealed. Another surgeon said that the x-ray was used only as a matter of extreme care. Viewing the testimony in the light most favorable to the plaintiff, it clearly showed that the attending surgeon used reasonable care, skill and diligence in diagnosis and treatment. A verdict for the plaintiff could not be permitted to stand, and a judgment resting on it would be set aside.

9. Adaptation of Human Saliva to Diet.—Mendel and his assistants detail experiments made by feeding persons with starchy substances to see whether there is any ground for the belief that diet will change the saliva, inducing adaptation to the diet furnished. There are a large number of variable factors aside from diet that affect the activity of the saliva. The author made use of Wohlgemuth's method of testing the concentration of amylose in the saliva. Individuals were treated for a period of from 7 to 10 days with a mixed diet; then without any starches for a second period, and later with carbohydrates alone. The results obtained would go to show that there is no adaptation of the saliva to the diet selected. In two vegetarians it was found that the saliva was no more active than in other normal individuals.

10. Chemistry of Urine in Pulmonary Tuberculosis.—It is claimed by King, who has done some original work in this line, that the urine would show wasting and an imperfect interchange of gases due to diseased lung tissue. Wasting should be shown by the urea excretion, and imperfect interchange by the elimination of the purin bodies. He tabulates the results in 52 cases, 43 of which represented various stages in patients who were able to be out of bed, the others being

bed cases. If the patient is near a fatal termination the urine will measure between 600 and 800 cc.; it will have a decided red color from pigments of blood cells that are being destroyed; it will show a urea reaction that is more than 4.00, and the urinometer reading will be between 20 and 25. Specific gravity undergoes little change. Uric acid is not increased to any great degree. Tuberculosis produces a relative increase in the principal products of nitrogenous metabolism. If the volume of urine expressed in hundred c.c. be multiplied by the urinometer reading, we shall get a so-called V-G factor; if this be low it indicates that the patient is not taking sufficient nourishment to sustain the body in a state of health. The author introduces various new reactions that are explained in connection with the tables.

17. **Hyperthyroidism.**—Hyperthyroidism, says Pitfield, may be so mild as to cause a few pains and aches, or so severe as to render the victim a bedridden, neurasthenic invalid; ugly, perhaps, and miserable; and often a complete puzzle for the medical attendant. Not always is the patient myxedematous. He or she may be so far advanced in the disease that the atrophic form obtains with emaciation and cachexia, so extreme that no subcuticle tissue, save bones and muscles, remain. Or the disease may be so slight that almost no skin changes are apparent, as in the cases reported by Pitfield. In fact, the patient may be rather fair to look on and yet have so many nervous symptoms as to be miserably ill, and in the eyes of many doctors a nervous, rheumatic crank.

Pitfield has seen in all nine cases in private practice. One patient was so myxedematous that she and her family preferred that she should not appear in public places, because she attracted the attention of nearly everybody by her hippopotamus gait. Two other patients were merely fat looking with puffy faces and swollen eyelids; one was a cachectic, prematurely old and withered-looking woman invalided for years, in whom there was but little suggestion of myxedema; two were comely, handsome women, one 35 and the other 53 years of age; another a thin, nervous little woman, a familiar type, with many ills and no myxedema. All had several things in common. All had had children. All had joint pains that were called rheumatism. The fat ones were all thought to have nephritis, the thin ones nervous prostration. And all without exception had had a galaxy of doctors who had misdiagnosed their ills.

Any woman approaching middle life or in the fourth decade, who has had a history of backache, an occipital headache, together with joint pains, dyspnea, asthenia, should be suspected of having hyperthyroidism, especially so if she has amenorrhea or had had it during the menstrual life. The treatment consists in the administration of thyroid extract.

18. **Peritoneal Infection.**—Analysis has convinced Stanton that the complete removal of the infection is the ideal procedure, and that removing the source of the infection and instituting a postoperative regime of peritoneal rest (Murphy's method) give almost ideal results in early cases of peritonitis. He failed to get good results, however, when he attempted to apply Murphy's method to patients with peritoneal infection of more than 40 hours' duration, though the most severe intermediate stage cases gave almost no worry at all when put on the Ochsner treatment. Once the peritoneum has become infected, Stanton believes that peritoneal rest is probably the most valuable single therapeutic means at command, and should be rigidly enforced whether one operates early or late.

23. **Anemic Ulcers of the Throat.**—Pohly believes that ulcers in the throat may be due to anemia or lowered vitality. He

has seen three cases, all in young women. The ulcer is round, small, with scanty secretion. There was no history of either tuberculosis or syphilis and no swelling of the glands.

29. **Tubercle Bacilli Excreted Through Bile.**—Maxson's observation points strongly to the fact that while the circulation of tubercle bacilli in the blood and their excretion in the bile is not proved, the evidence is sufficiently strong to make it very probable.

30. **Ascending Infection of the Kidney.**—In order to study the question of ascending infection of the kidney, Stewart concluded that it would be necessary to place uretero-intestinal implantation on a more firm basis. Formalin-hardened arteries suggested a way of doing this. The object was to have the arteries preserve the patency of the ureters and provide a way of making a more perfect anastomosis, which would lessen the possibilities of peritonitis. The preparation of these arteries was made by placing the carotid arteries of dogs in a formalin solution for 48 hours, after which time they were sufficiently hard to remain patent under pressure. Following this they were placed in olive oil and sterilized in an autoclave. Several experiments were performed to find out the result of passing these arteries diagonally through the intestinal wall. Autopsy in these cases showed that in about 2 weeks the arteries disintegrated and began to pass into the intestinal canal, leaving behind a rigid channel lined with fibrous tissue, the fibrous tissue formation probably being stimulated by the formalin remaining in the arteries. The following operation was first devised. The ureter was cut anywhere between the bladder and 3 inches from the kidney and an artery 2 inches long was inserted in it so that one-half was left uncovered. The uncovered portion of the artery was passed into the intestinal canal through an intermural channel from one-half to one inch in length, and the distal end of the ureter was sutured to the intestinal wall. The rigid artery containing ureter was covered by invaginating a portion of the intestinal wall and placing Lembert sutures; in this way the point of perforation of the intestine was covered and adhesions were permitted to form between the peritoneal surface of the intestine and the wall of the ureter. Thus the artery served to preserve the patency of the ureter at its point of attachment to the intestinal wall and to permit of a more perfect anastomosis with the intestine, in this way avoiding peritonitis. The object in making the intermural channel was to overcome the tendency to closure of the intestinal wound by muscular contraction, to place some distance between the end of the ureter, where it was attached to the peritoneal surface of the intestine, and the intestinal contents, and to have the urine empty in the direction of peristalsis and the fecal current. It was thought that these precautions would lessen the chances of ascending infection of the kidney. The above described operation with slight modifications was performed on 10 dogs. As a result

of his experiments, Stewart concludes that ascending infection of the kidney often takes place through either the lymph or the blood vessels of the ureter. When infection takes place in this way, it seems almost positive that the lymph vessels of the ureters are the carriers of the infection. It is probable that perinephritis is primary to the kidney involvement when infection of the lower urinary passages has caused perinephritis and kidney infection. The lumen of the ureter is less often a factor in ascending infection of the kidney than has previously been supposed.

33. Extract of Human Corpus Luteum.—In 9 cases Maits has used an extract of human corpus luteum made by Allen J. Smith in the University of Pennsylvania laboratories. He found that the extract of human corpus luteum possesses a distinct therapeutic action in osteomalacia, disturbances of the natural and artificial menopause and in hypofunction due to infantile uterus. In amenorrhea and in dysmenorrhea the treatment must at first be given each month. How long this must be continued before a permanent cure is effected and the injections can be omitted, Maits has not yet determined.

34. Febrile Mania of Unusually Long Duration.—Riesman's patient began to be troubled with insomnia, moodiness and causeless irritability of temper, which, however, did not attract attention at the time, being brought out only afterward in retrospect. Labor occurred on Jan. 4, 1909, and was entirely normal. On January 21, without any apparent cause, the patient began to have fever, which was thought to be due to a late puerperal sepsis; though this was, *a priori*, unlikely, as the confinement had been conducted with the greatest care by a skillful obstetrician. An enlarged spleen and a few suspicious rose spots on the abdomen seemed to warrant a diagnosis of typhoid. This probability was strengthened by two positive Widal reactions. A doubtful diazo reaction was also obtained. A slow pulse on several occasions when the temperature was high (82, for instance, with a temperature of 103) seemed also to favor the diagnosis of typhoid. On January 28, after 8 days of fever, the temperature fell by crisis, and the patient seemed to be perfectly well. She was, however, very much excited, did not cease talking of her speedy recovery, and constantly acclaimed it as a wonderful miracle. On the day following the fall in temperature, toward evening, she was unusually quiet, and as this followed a day of much mental exaltation a close watch was kept on her. Suddenly the patient began to scream and throw herself about so that it was necessary to hold her in bed. The eyes were wild and staring, and there was a white froth at the corners of the mouth. Coincidentally with the onset of the mania there was inaugurated a fever ranging from 99 to 104 F., which lasted practically without any intermission from January 30 to August 11, a total of 193 days. The pulse was variable. Despite the extraordinary duration of the fever, the urine remained almost unaffected, aside from being highly concentrated and loaded with urates. There was, barring a trace on one occasion, no albumin and no pus. Blood examination showed hemoglobin 90 per cent.; red blood cells, 3,200,000; white blood corpuscles, 1,000.

Several points present themselves for special consideration: First, the cause of the fever, lasting nearly 200 days. There was no evidence of tuberculosis; no signs of endocarditis, no enlargement of the spleen and no intercurrent temperature to indicate malaria, and the blood examination was negative. All those who saw the patient were of the opinion that she was suffering from some sort of toxemia. The nature of the infection remains unknown. Riesman thinks the case was one of infectious mania in which the mania is comparable to the delirium seen in acute forms of infectious diseases.

49. Abstracted in THE JOURNAL, June 4, 1910, p. 1889.

54. Treatment of Enuresis by Re-Education.—Applying the so-called method of conscious repetition of Brissaud to the treatment of involuntary micturition, Herrman has had the patient urinate at regular stated times, but every time he urinates he is directed to void a little, say 2 drams, and then stop; then void 2 drams more and stop, and so on, until the bladder is emptied. In this way the individual exercises the mechanism which controls urination; he trains and educates himself in the voluntary execution of the act. After this has been done two or three times under the direction of the physician the patient can carry it out himself.

56. Education of the Mother in Relation to Infant Mortality.—Sterling conducted an investigation of the experiences of a number of women whose special training in matters of health was definitely known. A set of questions, covering the occupation before marriage, the number of children, manner of birth, infant feeding, etc., were sent to 105 married graduates or former students of a successful normal school of physical education. Each of these women had spent one, two or three years at the school, where rational physical exercise, personal hygiene, and right habits of living were emphasized. Ninety-one replies were received and form the basis of this paper. The investigation covers a period of nearly 17 years, the first baby of the series being born in September, 1893. Of the 91 marriages 25 have been sterile to date. Of the 66 mothers, 56 were occupied in teaching for periods varying from 3 months to 12 years. In obtaining an average it was necessary to eliminate 10 of these, because their answers were too indefinite to show exactly how long they were thus occupied. The average length of time of the 46 who gave definite replies was nearly 3½ years. In the 66 fertile marriages, 112 pregnancies have occurred, the number per marriage ranging from 1 to 4. There are living to-day, at the end of almost 17 years, 100 children. This gives a total death-rate from all causes of 10.7 per cent.; 6 of the pregnancies resulted disastrously through abortions, premature birth, or birth causes at full term. In the series of 106 children surviving the ordeal of birth, practically 70 per cent. were breast-fed for periods varying from 1 month to 12 months, though in many instances artificial feeding was used as an aid to the breast; 77 per cent. of the mothers were able to nurse one or more children for one or more months. Of the 6 who died, 2 were nursed one or more months, and 4 were not nursed. Of the nurslings

who succumbed, 1 died of meningitis at 2 years of age and 1 of strangulation at 4 months. Of the 112 pregnancies, 75 resulted in normal or spontaneous births, 34 were not normal, and in 3 no report was made on this point. The death-rate among the children of these marriages is lower than that given for the registration area of the United States, which is about 14.5 per cent. Eliminating the so-called "unavoidable causes" connected with birth, the death-rate is markedly lower. The percentage of premature births is scarcely more than one-quarter that noted by Ballantyne in maternity hospitals. Abortions occur about one-quarter as frequently as in most series of cases. In the school which these young women attended subjects pertaining to health were of paramount importance. Sterling does not think that hygiene will ever become vital to the young women of the land until the academic councils of the various schools make as ample provision for such a course as they do for mathematics, or languages, or literature. Students will not take seriously a subject which the governing boards neglect.

57. **Treatment of Delicate Children by Class Method.**—Emerson is convinced that the class method is particularly well adapted to the proper treatment of delicate children. The spirit of competition, the "game" in it, has a powerful attraction to the child, aiding greatly in his management and control. The steady gain in weight in children following directions furnishes a strong incentive to the parents and the children alike. The class method makes the necessary instruction of the parents easy and effective. The results obtained each week remove prejudices and fears and convince in a moment, as if by magic, where hours spent in arguments fail. In the giving of instructions and directions to the parents and the children assembled together there is an enormous saving of time. The class method furnishes the best training school for the social worker. She can here learn what instructions are to be carried out; what the object sought. She catches the spirit of the work and is enabled to relieve the physician of a large mass of detail for which he has neither the time nor the energy to perform, and for which the social worker is the one person especially qualified by sex and training to carry out.

66. **Calomel to Increase Elimination in Pregnancy.**—The eliminative action of calomel is best obtained by giving from 1/20 to 1/10 grain 3 times a day, which course can be safely continued throughout pregnancy, says Coles, by omitting it for 3 or 4 days every 2 weeks. To get the best results from these small doses, the calomel should be well triturated with bicarbonate of soda, which increases its action and lessens the danger of salivation. For the past 12 years Coles has made this method of administration a routine treatment in all pregnant women in whom elimination was deficient, as indicated by headache, slight disturbance of the digestion, and diminution of solids and urea excreted in the urine. Usually

in less than a week after beginning this treatment these symptoms will disappear, and the urea and solids become normal. Then the patient is instructed to discontinue the powders or tablets until she again feels the need of them.

74. **The Incarcerated Gravid Uterus.**—In Stowe's case the urethral orifice was drawn upward behind the pubic bone so that the catheter was used with difficulty. The posterior vaginal wall was displaced anteriorly, the canal assuming the form of a crescent with its convexity forward. Douglas' pouch was filled with a hard, resistant mass which was slightly movable—the uterine fundus. The cervix lay behind the pubis and was firmly compressed against the bone. The sharp flexion between it and the fundus was easily made out. The anus was swollen and the anterior rectal wall greatly stretched. The rectum was empty. The bladder was palpable at a level of 5 cm. above the umbilicus. It was very tender to pressure. An attempt was made to pass the catheter without narcosis but it failed. Under anesthesia, a soft catheter was passed with great difficulty because of the traction on the urethra; 3 pints and 9 ounces of urine were finally withdrawn and the swelling in the abdomen immediately disappeared. After the urine had been removed, two fingers were passed in to raise the fundus above the promontory. This procedure failed. The patient was then held in the knee-chest position, the cervix secured with two strong volsellum forceps and the uterus forced into an oblique diameter and slowly—25 minutes—raised out of the true pelvis. An Albert Smith pessary was then introduced to maintain the organ in its natural position. A permanent soft rubber catheter was secured in the urethra to avoid further over-distention of the bladder, and this organ was irrigated with warm boric-acid solution every 3 hours. The catheter was removed in 36 hours. The bowels were moved by glycerin injections. The abdominal pain gradually subsided and the pulse fell to normal in 4 days. Hexamethylenamin was administered for several weeks as a urinary antiseptic. The further course of the pregnancy was undisturbed and the patient was delivered in due time. No complications were present.

75. **Cure of Varicose Veins by Intravenous Injections.**—If the injection of a corrosive solution, such as of mercuric chlorid, is directed against the endothelium of a vein instead of into the middle of the blood stream a complete and lasting occlusion of the vein can readily be accomplished. The irritation caused by the injection produces a hyperplasia of connective tissue cells, which encroach on the lumen of the vessel and ultimately obliterate it. Bernart has tried this treatment in three cases, with marked success in each one. The ultimate results in these are said to be equal to those of a radical operation. The technic of the procedure consists of applying a tourniquet some distance above the point to be injected so as to make the veins tense and firm. The site selected is washed with alcohol or ether and a 2-inch small gauged platinum needle is passed up to its shoulder into the lumen of the vessel. The tourniquet is then loosened and the solution is injected against the wall of the vein. While injecting, the needle is partially withdrawn so as to cover a wider area of the endothelium.

86. Local Anesthesia.—Watson holds that the strong solutions are equally or more dangerous than general anesthesia, while the weak solutions are the safest of all methods of analgesia. When local anesthesia is possible he prefers cocaine to ether or chloroform, because he believes it to be less dangerous, from observations on its use during the last 23 years in over 10,000 operations not only without a death but without any disturbance of the "equilibrium physiologic" of the patient. On the strength of the solution, he says, depends the rapidity, intensity and duration of the anesthesia. The technic of the injection is always delicate; it varies with each region, with each operation and in each patient. The technic must be learned with a knowledge of its application and adaptation to each individual case. Success in the use of local anesthesia depends on the patience, special training in the technic and an intimate knowledge of sensory nerve distribution. Because of the slower appearance of complete anesthesia with the weaker solutions, surgeons who begin operating as soon as the injection is finished will often fail with local anesthesia. Nerves, no matter how small, should never be handled previous to cocaineization; to do so will lessen the confidence of the patient in the method, cause unnecessary pain and a certain amount of shock. For a similar reason lacerated and contused wounds of the extremities should not be prepared for operation previous to cocaineization. Without the absolute confidence of the patient, work under local anesthesia will tax the patience of the most skillful surgeon; therefore, it is very important to always proceed slowly during the early stages of an operation under cocaine.

Watson considers the addition of adrenalin unnecessary to prevent poisoning when the weak solutions are used, besides it increases the tendency to secondary oozing of blood into the tissues. The point of the needle should always be in sight (intra-epidermal), otherwise an unnecessary amount of solution will be required to anesthetize the sensory nerve terminals. It is impossible to insert the needle too superficially. Local anesthesia can be employed in any part of the body where the nerve supply can be controlled. With a proper selection of cases, Watson asserts, the majority of surgical operations can be performed under local anesthesia. He recently had a case in which an infected wound of the foot was freely incised under vein anesthesia without the knowledge of the patient. A tourniquet was applied just above the knee and 15 c.c. of a 0.2 per cent. cocaine solution was injected into the external saphenous vein in the upper third of the leg. Anesthesia was complete in 30 minutes, extending as high as point of injection. Sensation reappeared as soon as the tourniquet was removed. No untoward symptoms were present at any time.

96. Vaughan's Split Products.—This article is a confirmation of Vaughan's work and theory.

97. Anaphylaxis.—The experimental work reported on by Anderson and Frost is chiefly a study of the anaphylactic antibody (allergen) designed as a study of the principles of anaphylaxis rather than of its details. The authors have given special attention to the quantitative relations existing between allergin and its specific antigen, also to the relation of allergin to the conditions of hypersusceptibility, anti-anaphylaxis, and immunity. The wealth of detail in the paper precludes making an abstract for these columns.

98. Typhus Exanthematicus.—It is McCampbell's belief that European typhus fever and tabardillo are probably identical. The virus of tabardillo cannot be cultivated by the ordinary methods. There is nothing distinctive in the pathology of tabardillo. The most characteristic change is the extensive waxy degeneration of the heart and voluntary muscles. The blood taken from the rash in the macular stage in a large percentage of cases shows small micro-organisms which resemble the beaded bacilli of the hemorrhagic-septicemia group. These micro-organisms are not present in other parts of the circulation and are found only during the rash. The erythrocytes of tabardillo patients drawn during the rash show a peculiar vacuolization in a large number of instances. The vacuolization is not general throughout all the corpuscles. This suggests the possibility of an intracorporeal parasite. The virus of tabardillo can probably be transmitted to the monkey, producing a low febrile infection, and it is probably not filterable. The louse could be directly connected by experiment with the carrying of the virus of tabardillo.

99. Ascitic Fluids in Cancer.—The result in Weil's experiments have been almost entirely negative in character—that is to say, they have not indicated the existence of any specific character such as would serve to differentiate with certainty fluids derived from cancerous individuals from those of another origin.

100. Bacteriemic Theory of Tuberculosis.—The authors claim that there is no proof to show that the acid-fast organisms found by Rosenberger and others in their preparations of sedimented, citrated blood from tuberculous individuals were originally present in the circulating blood of these individuals, or that these bacilli are tubercle bacilli. On the contrary, it now seems reasonable to suppose that these acid-fast organisms were accidentally introduced into the microscopic preparations and are to be considered as contaminations. There appears, therefore, to be no adequate reason for changing previously established conceptions concerning the conditions governing the presence of tubercle bacilli in the circulating blood.

102. Intestinal Absorption and Pulmonary Anthracosis.—The alimentary route of pigment failed to lead to pulmonary anthracosis in guinea-pigs after ingestion and inhalation

experiments in which amounts of pigment were administered far in excess of amounts ingested under ordinary conditions. Intestinal absorption of inert particles has been demonstrated by proper experiments, but only after the repeated ingestion of amounts far in excess of those entering the alimentary tract under normal conditions. Apart from the alimentary route—which is practically a negligible factor—Montgomery says that there is only the respiratory route which may lead to pulmonary anthracosis occurring (1) accidentally, as found at autopsy in animals and human beings, and (2) artificially, the result of inhalation experiments. This is confirmed by inhalation experiments.

104. Gonorrheal Salpingitis.—According to Gurd, a much larger percentage of cases of salpingitis are due to the gonococcus than is usually supposed; at least 80 per cent. of the cases in Gurd's series are probably due to that organism. Old pus collections may become the nidus for infection by other organisms such as the colon bacillus. This organism, in all probability, enters the already present pyosalpinx by direct passage through the tissues from the frequently adherent sigmoid. The appearance of the tubes examined in this series suggests that the exacerbation of symptoms which occurs, periodically, in cases of chronic salpingitis is due to the repeated involvement of the peritoneal covering in an acute inflammatory process. The great preponderance of plasma cells over the other inflammatory cells, as well as the localization of the lesion, chiefly in the mucosa and submucosa, is very suggestive of the gonorrheal origin of an affection. The gonococcus invades the tube by means of the continuity of surface of the mucosa from the uterus. The histologic picture is probably to a great extent dependent on this fact.

115. Fatal Apnea and the Shock Problem.—The acapnia hypothesis, according to Henderson, requires the prevention of excessive pulmonary ventilation. The administration of morphin and full anesthesia diminish the activity of respiration under pain and thus prevent acapnia. If, however, one administers morphin or chloroform to a subject after he has suffered for some time, fatal apnea is hastened unless carbon dioxid is also administered. When a moderate degree of shock has been induced by irritation of afferent nerves or by exposure of the viscera. Henderson finds that it is possible to induce a rapid recovery of arterial pressure by the infusion into a vein of normal saline or of Ringer's solution saturated with CO₂. Then the animal is made to breathe an atmosphere of oxygen and CO₂ or else merely of oxygen supplied at the end of a long tube. Under these conditions it rebreathes the oxygen several times and thus the CO₂ which the subject itself produces is utilized to stimulate respiration and increase the otherwise insufficient oxygen intake. If the degree of shock previously induced is not too severe, not only do these measures of relief induce a rapid restoration of arterial

pressure and respiration, but this restoration is maintained. On the other hand, in profound shock these measures fail to effect an ultimate recovery. Indeed, after the diminished blood stream has resulted in tissue asphyxia and acidosis no measure of relief, except perhaps hypertonic saline or transfusion of blood, can be of much use.

There are two methods of treating acapnia failure of respiration under anesthesia. If a soft catheter is inserted in the trachea down to the bifurcation of the bronchi and a gentle stream of oxygen gas is supplied, according to the method devised by Volhard, the subject will lie for a very long time indeed in complete apnea. By this method a supply of oxygen ample for all the needs of the tissues may be maintained. The oxygen should, however, be measured, and for a man should be not less than 400 c.c. per minute. Under these conditions in animals reaccumulation of CO₂ proceeds relatively rapidly. In one case Henderson has seen a dog in acute acapnia lie for 12 minutes without the slightest respiratory effort and at the end of this period recommence normal breathing. The oxygen jet had supplied ample oxygen for the combustion of the acidosis substances which would otherwise have been produced. This method of Volhard, therefore, accomplishes a double object. It prevents the acidosis of asphyxia at the same time that it allows the subject to recover from acapnia. Another method of restoration of breathing has been tried in dogs during apnea with strikingly successful results. It consists in administering air or oxygen containing 5 or 6 per cent. of CO₂ and in starting the subject to breathing by one or two artificial respirations. As soon as the normal tension of CO₂ in the lungs is thus restored spontaneous breathing immediately recommences and is maintained as long as the inspired air contains a sufficient quantity of CO₂ to stimulate the respiratory center. It will, Henderson thinks, be advisable to use for this purpose oxygen and CO₂, and not merely air plus CO₂, for the purpose of preventing the acidosis of which he speaks. Indeed, oxygen and CO₂ would combine the advantages of both methods for preventing fatal apnea. It must be remembered that CO₂ is a powerful drug and one to be administered in small quantities only—never in greater concentration than 5 or 6 per cent. Henderson has devised a simple gas meter which he believes may be useful for measuring the small quantities of CO₂ to be added to air or oxygen as a respiratory stimulant. It would be better to have the gases already mixed.

117. Intrathoracic Displacements in Pulmonary Tuberculosis.—This paper deals with the changes brought about in intrathoracic relations as shown by skiagrams of cases of pulmonary tuberculosis, studied clinically before and after taking of the x-ray plate, and is supplementary to a paper published in the *American Journal of Medical Sciences*, May, 1910, and abstracted in *THE JOURNAL*, May 28, 1910, p. 1822.

125. Salivary Secretion.—It was found by Henderson that iodids are excreted by the salivary gland, but that their

always. Of his series one was in the back of the sheath of the rectus, one in the conjoined tendon of the internal oblique and transversalis, another in the substance of the external oblique muscle above the eleventh costal cartilage, and finally, one consisting of fibrous tissue with unstriated fibers in the left inguinal canal, and, in Lockwood's opinion, in the round ligament of the uterus.

The anatomic situation of these tumors, says Lockwood, ought to be noted, because some are spindle-cell sarcomata, which return after removal, and ultimately kill the patient. To extirpate a spindle-celled sarcoma successfully, it is necessary to make a very wide removal of the muscle in which it is growing. To the naked eye these tumors have the ordinary character of the fibrous structures of the body. Perhaps they may look a little redder, but there is nothing distinctive in the naked-eye appearances. Some of them are like the gizzard of a fowl in shape, color and consistency. Some have a capsule.

With regard to the clinical history of these tumors, the patient says that they are usually painless, and are not tender to the touch. The fibromata are of long duration; they take years to grow. In the case of a man with one behind the sheath of the right rectus, there is a history of fourteen years, and others had histories measured by years. The growth of sarcomata, on the other hand, is measured by months, so that an accurate clinical history throws some light on the nature of the tumor and the course which it might pursue. The surgical treatment of these tumors of the abdominal wall depends on their pathologic characters. An encapsulated tumor may be removed from its capsule, especially when one knows that the tumor consists of fibrous tissue. But if there is no capsule and if the tumor is growing along one of the abdominal muscles then the removal becomes a matter of great difficulty.

3. Aid to Diagnosis in Malignant Disease.—A careful examination of the urine in malignant and non-malignant cases convinced Royle that the uric acid output in malignant disease is greater than in ordinary hospital patients under similar conditions and taking the same diet, and that the phosphate excretion is much lower in malignant than in non-malignant patients under corresponding conditions and taking the same diet, and that it falls with the advance of the disease. The resulting ratio of

$$\frac{\text{phosphates}}{\text{uric acid}}$$

is much lower in malignant

cases than in the corresponding controls done in non-malignant cases. Also, this ratio falls throughout the course of the disease. These conditions, Royle thinks, are largely, though not absolutely independent of the particular form of diet, the same changes being noted in malignant patients on any diet as compared with ordinary hospital patients on a similar diet. With diets consisting largely of milk, however, and of little or no meat, lower uric acid figures, often higher phosphates, and in most cases higher ratios are given in malignant and non-malignant patients than would be the case if the patient were on "common diet."

From the results obtained, Royle believes that an examination of the urine will prove of great value as an aid to diagnosis in obscure cases of cancer, especially in cancer of the alimentary canal and abdominal organs, which is often difficult to distinguish from such diseases as gastric ulcer, tuberculosis, gall-stones, etc. In order to apply this test, it is necessary to estimate the uric acid and phosphate content of the urine, and to consider the figures separately and then take into account the

$$\frac{\text{phosphates}}{\text{uric acid}}$$

ratio, any ratio below 4

being suggestive, especially if it remains low on several occasions, and any ratio below 3 is almost diagnostic of malignant disease or a blood disease.

4. Occluding and Suboccluding Ligatures.—The point made by Bonney is that suboccluding ligatures should be avoided.

6. Artificial Pneumothorax.—Holmboe reports in detail a case of moderately advanced pulmonary tuberculosis in which

the production of an artificial pneumothorax resulted in wonderful improvement after serotherapy had failed. Cough and expectoration ceased, temperature and pulse became normal, weight increased 20 pounds, and the patient was able to work several hours each day. Similar results were obtained in four other cases.

9. Effect of Radium on Healthy Tissue Cells.—This preliminary note is the result of some experimental work by Mills on the comparative effects of radium on normal mouse tissues. The radium was applied over the anterior abdominal wall and the subsequent changes in the liver tissue were observed. The applicator used was one of 500,000 units and was guarded by a shield which cut off the A and B rays, while allowing the more penetrating Y rays to pass through. It was applied for 30 minutes in each case. The mice were killed at varying intervals after exposure and the liver examined microscopically. The earliest definite change noticed occurred about one hour after irradiation. The liver cells in this section were more granular than usual, and there were none of the clear glycogen-containing vacuoles which are present in the normal mouse liver. Otherwise the liver cells themselves appear normal. The connective tissue elements also showed the early stages of a reaction. This was manifested by the presence of numerous groups of round and spindle cells in the neighborhood of the veins. There was distinct hyperemia, but at this stage there was no general increase of the mesoblastic cells. Three hours after irradiation the liver cells were profoundly altered. The protoplasm was deeply granular and the nucleus stained very clearly and was considerably swollen. The whole cell also was slightly increased in size, but not nearly to such an extent as the nucleus. The areas of mixed-cell infiltration round the veins were larger and more numerous. Sections taken 6 hours after irradiation showed that the liver cells had become more normal in appearance. The protoplasm was no longer granular, but the nucleus was still enlarged. The hyperemia was less and there was less infiltration with connective tissue cells than in the previous section. In 24 hours the vast majority of the liver cells appeared normal. Scattered about the section, however, there were a few cells which appeared to have degenerated completely. While these changes were found in the liver generally, there was in most of the sections a place near the edge where the cells had suffered a greater and permanent change. There was in the sections taken 3 hours after irradiation a mass of liver cells which had completely lost their structure. A similar condition was found in the sections examined up to the eighth day after irradiation, and in the later ones some signs of organization of the affected part were observed. Presumably this mass of necrosed tissue corresponded to the spot immediately over which the radium was applied, and represents the effect of the rays at a very close range. It is of interest that in no case was any inflammation of the skin observed.

In the sections taken 14 and 15 days after irradiation, however, there were obvious signs that a second or late reaction was taking place. This was confined to the connective tissue elements and consisted of a marked general infiltration of the liver with lymphocytes, connective tissue cells, and a few polymorphonuclear leukocytes, and this to a greater extent than in any of the sections taken during the few days immediately following irradiation. There were also large masses of similar cells clustered round the veins. These changes were associated with a general hyperemia. No area of necrotic cells was observed. It would appear that this is the histologic basis of the "radium reaction" observed clinically by radiographers, and it is of interest to note that it is confined to the connective tissue elements. This late reaction lasts longer than the initial one, for 20 days after irradiation the liver was still found to be in a similar condition.

26. Transmission and Prevention of Malaria in Panama.—This paper details a most exhaustive study of many phases of malaria, and for purpose of reference only, the following list of points discussed are given: Anophelines of this region; collection of larvæ; breeding out mosquitoes and methods of feeding; biting-infecting experiments; estimation of gametes; care of mosquitoes after feeding; method of examining for zygotes and sporozoites; description of the malarial parasite in the mosquito; table of infecting experiments; notes and conclusions from table of infecting experiments; limit of infectiousness of man; notes on the bionomics of anophelines; effect of salt or sea water on larvæ; experiments with larvacides; experiments with agents destructive to vegetation, grass and algae; experiments with screening of various mesh; relative value of wire screening of various composition, based on practical tests and chemical analysis; note on the value of the practice of killing anophelines found in quarters and barracks; effect of quinin on the parasite in mosquito and man.

On the last point mentioned, Darling says that the effect of quinin administration is to make the gametes gradually disappear from the peripheral blood by the destruction of the young forms, the gametes being phagocyted by splenic and hepatic endothelium. It is concluded that quinin, 10 grains, thrice daily, in solution, will gradually reduce the sexual form of the parasite in man to a non-infective minimum in from a few days to a few weeks, depending on the severity of the infection. In simple tertian malarial fever, gametes disappear from the peripheral blood within two or three days under quinin treatment, and generally disappear even when quinin is withheld, even if the patient is at rest. There are never so many gametes in the peripheral blood in simple tertian malaria as in malignant tertian malaria. As a consequence, one never finds so many simple tertian zygotes as malignant zygotes in infected mosquitoes.

27. Effect of Cold on Diseases in Small Animals.—The animals subjected to the influence of cold were guinea-pigs, rats and mice. They were placed in cages, well-bedded and well-fed, fat and proteid especially being provided in their diet. The diseases brought under the influence of the cold were chiefly various trypanosomiasis, with, in addition, tuberculosis (bovine), cancer (in mice), tetanus, and spirochetosis. The only animal which failed to show trypanosomiasis after inoculation with *T. brucei* was one in the cold chamber. Twelve

mice were inoculated with cancer, and 6 put into the cold chamber: 5 lived 50, 51, 56, 70 and 90 days respectively, whereas of the 6 controls, 2 lived 56 and 76 days respectively. Of the remainder, 3 controls failed to develop tumors, and 1 each in the control and cold chambers died within a few days of inoculation. Some mice were also infected with *Spirochaeta duttoni*, but no appreciable influence on the course of the disease could be observed in them.

Five guinea-pigs with tetanus were placed under observation. One, injected with 1/500 c.c. of a culture and placed in a cold chamber, died in 9½ days, but it is very doubtful if it died of tetanus; 2 injected with 1/1,500 and 1/1,000 c.c. respectively and kept as controls never showed any symptoms; while 2 injected with 1/500 c.c. and placed, 1 in the cold chamber and 1 as control, died with similar symptoms in a similar time—something over 50 hours.

An Englishman suffering from sleeping sickness of some 3 months' duration had a course (interrupted for some days) of 12 days, or some 53 hours in all, of cold air. The temperature was gradually decreased till 24 degrees F. was reached. He himself said he felt much better for the treatment, which acted on him as a tonic, but in the short period he was under observation no visible diminution was apparent in the number of trypanosomes in the blood.

Six guinea-pigs were inoculated with bovine tuberculosis (0.1 mg. culture) and 3 placed in the cold chamber and 3 outside, with, of course, uninoculated controls in both cases. The uninoculated controls thrived, except that 1 in the cold chamber died after 34 days of no obvious cause, there being only a little lung congestion evident in post mortem. Of the inoculated, all are still alive, and those in the cold chamber have now been in it 137 days, and seem quite fit and well. One female has aborted twice, but whether from the cold, the tuberculosis, or other cause, cannot be stated definitely. Four guinea-pigs have since been inoculated with human tuberculosis, and 3 of these are at present under observation, 1 having died soon after inoculation. Several rats have been inoculated with cultures of pneumococcus, but so far no marked difference has been observable in their symptoms, whether in or out of the chamber, and none has died, so that they remain under observation, and the final result will only become apparent later.

41. The Lesions in the Thyroid with Exophthalmic Goiter.—Alamartine has become convinced by his clinical experiences and research on resected goiters that exophthalmic goiter is generally the result of some toxi-infectious thyroiditis, entailing cirrhosis with hypertrophy of the gland and insufficient or perverted secretion. Rheumatism and tuberculosis, he asserts, are the two infections whose causal influence has been most effectually demonstrated.

- 44 *Treatment of Depression of the Skull in New-Born Infants. (Traitement des enfoncements du crâne chez le nouveau-né.) P. Commandeur.

44. Depression of the Skull in New-Born Infants.—Commandeur warns of the serious consequences liable to follow birth traumatism causing depression or indentation of the cranial bones. The immediate mortality is about 14 per cent. In case of survival there may be hemiplegia, convulsions and epilepsy or idiocy as the child grows up. Sometimes the depression spontaneously springs back into place; this is more likely to occur with parietal than with frontal depressions. If the depression is causing symptoms it should be corrected immediately, and a frontal depression should always be corrected, he affirms, without waiting for symptoms. If there are no symptoms from a parietal depression temporizing is allowable but never for more than 10 days. He has found 46 cases on record in which the depression was artificially corrected; infection was responsible for the 3 possibly operative fatalities. Correction of the depression put an end at once to the symptoms; they were more severe with the frontal depressions. Vicarelli has improved the corkscrew method and has applied it in 14 cases with constant success; in 5 cases in which it was applied by others, 2 of the infants succumbed to meningeal hemorrhage. In the 27 other cases the depressed part of the bone was pushed into place from below, entering through the sutures or an incision in the bone. Commandeur commends the corkscrew method as preferable when indications permit, especially when the soft parts are incised and drawn out of the way and the Heine or modified corkscrew is inserted directly into the bone. Full directions are given for this and the other modes of correcting the depression and the cases in which this treatment was applied are reviewed with some medical cases bringing the total to 52. All emphasize the dangers of delay.

50 *Repeated Lumbar Puncture in Treatment of Fracture of Base of Skull. A. G. Apostolides.

46. Chancre in the Tonsil.—Le Play and Sézary report a case in which the chancre developed in the left tonsil, the lesion presenting the aspect of an ulceromembranous sore throat. The persistence of the lesion for three weeks notwithstanding systematic gargling with potassium chlorate was suspicious although there was no enlargement of glands in the vicinity and the ultramicroscope revealed spirochetes. The diagnosis of syphilis was confirmed by a roseola that developed soon afterward and the positive Wassermann reaction. There was no fever at any time. In a second apparently similar case there was slight fever towards night and a slight tendency to glandular enlargement; but the ultramicroscope revealed the spirilla and fusiform bacilli of Vincent's angina and the course of the case confirmed this diagnosis. In both cases the microscopic field contained two or more specimens of the *Spirochæta refringens*.

49. Periodical Intestinal Disturbances as Regulatory Process.—Marcou explains the sudden transudation into the bowel, which is the common feature in all cases of chronic diarrhea, as sometimes an automatic means of clearing out the poisons in the system when they have accumulated beyond a certain point. The diarrhea in chronic kidney disease is merely an exaggeration of this process of cleaning out the body such as occurs in the neuro-arthritic on a milder scale. Schmidt's "diarrhea from transudation of an easily putrefying fluid" also belongs in this class as also some of the attacks of

gastrointestinal trouble that come on after weaning, such as Herter and Heubner have described (THE JOURNAL, March 13, 1909, page 913, and Jan. 22, 1910, page 330). The attacks of recurring enterocolitis can thus be regarded as an automatic regulating process when they occur in individuals with an inherited tendency to auto-intoxication, belonging to the great family of neuro-arthritics, that is, those predisposed to nervous and joint disturbances. This conception enables the physician to tranquilize the patient during these recurring bowel troubles, teaching him to regard them as an effort by Nature to throw off accumulated poisons, a natural purification, which must be borne in patience, and that there is no necessity for doing the Wandering Jew act from doctor to doctor which is so often the practice of patients of this class. The violence and frequency of the attacks can be influenced by treatment of the underlying neuro-arthritic diathesis, reducing the opportunities for accumulation of toxins by dieting, and toning up the nervous system in general. At the same time, Marcou warns against too precise instructions in regard to the diet as the patient may learn to dread all kinds of food.

50. Lumbar Puncture after Fracture of Base of Skull.—This communication from Smyrna emphasizes the advantages of lumbar puncture both for differentiation and cure of fracture of the base of the skull, reporting a case in which there were signs of meningitis after a fall on the head, intense headache, incoherent babbling, the pulse being 50. Lumbar puncture released about 40 c.c. of bright red fluid under high pressure and the patient roused at once, the headache disappeared and the mind became clear. Some of the symptoms returning later other punctures were made with equally good effect. The fluid was limpid at the fourth puncture and recovery was soon complete and there have been no disturbances during the 10 months since. In this case the puncture was made the same day as the accident, but in the second case the meningitic symptoms did not develop for a few days and the puncture was not made until the twelfth day after the accident; 4 punctures in the course of 6 days also resulted in practically complete recovery although this patient still has total anosmia. The puncture not only relieves the brain from the pressure of fluid but by releasing this fluid it washes out quantities of germs which otherwise would find in the bloody fluid an excellent culture medium.

61 Idem. (Wert des Isosylsinebefundes für die Diagnose bösartiger Geschwülste.) B. Agazzi.

52. Resection of Posterior Roots for Spastic Paralysis.—Foerster here gives the theoretical bases for the operation generally known by his name and reviews the indications, technique and results. In every case in which it has been applied to date the spastic contractures were mitigated or entirely cured, he states, adding that adjuvant measures are indis-

pensable to produce the best ultimate results. He cites 16 cases in which the operation has been performed, but the list is actually much longer.

53. Test of Kidney Functioning by Elimination of Diastase in the Urine.—Wohlgemuth applied this test first on dogs and then in 50 clinical cases, the reliability and accuracy of the findings sustaining, he declares, the value of this simple method of testing kidney functioning; the test is complete in half an hour. He has two sets of 10 test-tubes, in which he pours from 0.06 to 0.6 c.c. of urine in turn and then to each tube he adds salt solution to bring the total contents of each to 1 c.c. He then adds to each tube 2 c.c. of a 1 to 1,000 solution of "soluble starch." The stands with the tubes are then set in the water bath at 38 or 40 C. for half an hour after which 1/50 normal iodine solution is added to each tube, a drop at a time, until the tint changes permanently. The findings are obtained by comparison of the action of the diastase according to the concentration in starch in the different tubes, each set containing the urine from only one kidney, segregated by catheterization of the ureters. The urine does not have to be filtered, and it can also have served previously for determination of the freezing-point; a little blood does not affect the test. In health, both human beings and dogs seem to eliminate approximately equal proportions of diastase with both kidneys. In a typical case reported, the freezing-point was 1.28 in the right urine and 0.53 with the left; sugar, 1.6 per cent. with the right, and 0 with the left; indigocarmin test: green after 7 minutes and blue after 15 with the right urine, the left urine still colorless; the index from the diastase test after 30 minutes was 10 in the right kidney and 3.33 with the left; after 24 hours, 25 with the right and only 8.3 with the left. The findings with all these functional tests thus harmoniously agreed, while the diastase test is even more sensitive than the indigocarmin and phloridzin tests as it often gave positive findings when the other tests were still negative.

57. Therapeutic Transfusion of Blood.—Schultz reports a good outcome in 10 cases in which he made a transfusion of defibrinated blood in serious anemia, after having tested the action of the alien blood on the patient's blood corpuscles. He was thus able to refrain from using blood that displayed any tendency to induce agglutination or hemolysis. Even in the one case in which this was not done, and the transfusion induced acute collapse, chill, fever to 104 F. and edema, yet the general effect seemed to be good after these symptoms had subsided. The transfusion had a markedly favorable effect in all the cases of secondary anemia, but in pernicious anemia the benefit was only transient.

62 *Indications for Prostatectomy. F. Suter.

63 Progress and Limitations in Efforts to Insure Asepsis Before, During and After Operations. (Keimprophylaxis bei der Wundbehandlung und Streben nach Präventivmitteln gegen die Wundinfektion.) C. Brunner. Commenced in No. 21.

62. Indications for Prostatectomy.—Suter operated last year in 10 cases of prostatic retention, all by the suprapubic route by Freyer's technic. The functional results were good in every case except one in which the hypertrophy proved to be malignant. In the case of 2 comparatively young men he performed the primary prostatectomy without delaying for catheter treatment as he was anxious to ward off infection of the bladder. The virility was not impaired in any case by the operation; this is the principal advantage of the Freyer technic.

65. Transient Blindness from Contusion of the Skull.—The patient was a boy of 12 who had been run over by an automobile and brain substance protruded from a gash in the skull. The boy was unconscious at first and was blind when he roused, the amaurosis being complete with no perception of light. Vision then gradually returned and by the third day was normal and it has persisted so to date, the other injuries soon healing.

68. Amenorrhea and Tertiary Syphilis.—The amenorrhea had lasted for 6 and 8 years in the 3 cases reported; the women were from 28 to 42 years old. All were suffering from severe manifestations of tertiary syphilis and under the mercury and iodid they were taking menstruation returned; it was quite normal in the younger women but assumed a vicarious form in the other, epistaxis recurring regularly at the menstrual period. The cases emphasize the importance of specific treatment for amenorrhea in women whose history suggests the possibility of syphilitic changes in the ovaries.

80. Atypical Forms of Intermittent Limping.—Curschmann regrets that physicians do not make a practice of examining the arteries in the foot more frequently as they thus miss the explanation of many puzzling syndromes. The diagnosis of arteriosclerotic intermittent limping is further rendered more difficult by the atypical forms occasionally observed, as in 2 cases he describes in which the patients had intense pains come on while they were at rest, especially at night, and the pains were dissipated by getting up and walking—the syndrome thus being exactly the reverse of the classical type. In both the cases there was a history of syphilis 10 or 11 years before, and in both the affection came on with a sudden onset. These cases resemble 2 recently described by Erb as "arteriitic dysbasia." In some other atypical cases reported by Curschmann there was a combination of intermittent limping affecting the left foot, vascular cramps in both hands during work, with occasional motor disturbances, actual dyspraxia, and at the same time intermittent intense pain in the left arm. A similar syndrome was observed in other patients free from arteriosclerosis, and he is inclined to explain it as an abnormal tonicity of the smaller arteries, a pure angiospastic form of dyspraxia. In another case the presumptive diagnosis is angiospastic intermittent limping developing in the course of a climacteric vasomotor neurosis.

was on the side toward the opening in the skin, which was tamponed. Four days later, the gangrenous intestine perforated as anticipated at the point thus left exposed, and fecal matter was voided here as well as by the rectum for a time but the fistula gradually tended towards healing. In a second case in which this technic was applied the fistula healed completely in 25 days.

114. Stretching the Sciatic Nerve in Treatment of Perforating Ulcer of the Foot.—In the first of the 4 cases reported the trophic disturbances had been cured by stretching the plantar nerve, but the ulcer in the foot recurred before the year was out, and this time the sciatic nerve was isolated and stretched. The cure was soon complete and has been permanent during the 2 years since. In the second case the sciatic was stretched to cure coexisting sciatica and it cured at the same time the ulcer on the foot which was evidently secondary to the trouble in the sciatic nerve. The results were equally good in the 2 other cases. His patients were men 25, 49, 60 and 70 years old, and 3 were hard drinkers. The nerve was stretched under morphin-chloroform general anesthesia and the ulcer was curetted and dressed at the same time.

THE PROPOSED ENLARGED NATIONAL PUBLIC HEALTH ORGANIZATION

A DISCUSSION OF PLANS FOR ITS ORGANIZATION

GEORGE B. YOUNG, M.D.

Surgeon, United States Public Health and Marine-Hospital Service;
Stationed at Chicago in Charge of the Marine Hospital

CHICAGO

A careful reading of the hearings before both the Senate and the House committees, which have been considering the Owen and other bills, designed to coordinate and increase the public health activities of the general government, compels the conclusion that the committees obtained very little that would be of value in solving the problem before them. That problem may be stated to be the drafting of a law which will give adequate recognition to the importance of national public health work, and at the same time will avoid being made the instrument for exploiting the theories of a great variety of well meaning people whose preference for some particular plan of organization, or enthusiasm for some particular form of research or educational propaganda, is in inverse proportion to their knowledge of the limitations of national health legislation on both the practical and the constitutional sides.

NATURE OF PROBLEM

Broadly speaking, the problem involves two questions: (1) What relation shall the public health organization bear to the other executive organizations of the government? and, (2) How shall the organization be constituted in order to give it at once the greatest practical efficiency within the limits of that relation?

What practical assistance, then, did the committees get from the voluminous testimony presented to them? Let us analyze it and see.

ANALYSIS OF THE HEARINGS

The witnesses fell naturally into two classes, those advocating legislation along the lines of one or more of the pending measures, and those opposed totally or in part to the principle underlying those measures. The second class can be quickly disposed of because, their efforts being directed toward preventing action along the general lines followed by most of the pending bills, their ideas could not be of much use in shaping legislation in furtherance of the object of those measures.

An exception to these must, however, be made in regard to several of the purely legal points raised by Ex-Governor Bates as attorney for certain organizations opposing legislation, for while most of these points were more adroitly than convincingly presented, there were some others which raised questions which, it must be

admitted, had apparently never occurred to many of the proponents of the measures under consideration.

Passing to a consideration of the statements of the proponents, they are readily classifiable into several pretty definite categories. First in point of numbers, those whose statements were largely confined to a presentation of the great importance of expanding the scope of the national public health activities, to an enumeration of the problems for the elucidation of which only national agencies seemed adequate, and to explanations of the enormous advantages, racial, social, educational, economic and sanitary, which would follow the solution of those problems. Some of these witnesses had incidentally something to say about the specific measures under discussion, but for the most part their statements contained nothing that would either inform the committee as to what the government was already doing, what it should do, or how it should do it.

The second class comprised those whose arguments were directed to supporting the fundamental proposition that the proposed increase in governmental activities required the establishment of a new executive department, and, in so far as their arguments may be accepted as valid by the members of the committee, their testimony can be regarded as helpful.

The third class comprised those whose testimony concerned the desirability of transferring to the new organization certain specific activities at present located in existing organizations of the government, and while the witnesses concerned had very little if anything to say definitely as to the extent to which these activities were to be transferred, or the manner in which they were to be correlated with other activities in the organization of either existing or new public health agencies, still, so far as it went, this testimony can be considered as helpful, but like that of the other groups, it did not go far in the direction of constructive suggestions. There were two exceptions to this. Before the Senate committee Dr. Kober and Dr. Wiley did present constructive suggestions as to the activities to be transferred to the new organization, and explanations of reasons for such transfers.

Disregarding the statements of the first class of the proponent witnesses as not of immediate constructive utility, what does all the rest of it yield? First, arguments as to what kind of a head the new organization shall have, arguments which go very superficially into only one of several of the suggestions offered as to his rank, and the method of his selection; second, fragmentary discussion of what agencies shall be under him—nowhere any presentation either of the broad general questions involved in designing the proposed organization, or the systematic study of the details necessary to make that organization effective.

This is in no sense intended as a criticism of the motives or ability of the witnesses. It simply points out the inherent difficulties in properly presenting such questions to a large committee by means of testimony of witnesses, whose very eminence in various lines of human endeavor, while it explains their being put forward as specialists as to certain phases of the subject, causes them to take a rather narrow view of it and necessarily produces a somewhat fragmentary and inconclusive mass of testimony.

Now it appears to me that, aside from the question of who shall be at the head of any organization, the real matters to be considered are what in general terms are the kind of activities that may be properly included in a national health organization at the present time, how far they already exist in one place or another, and how far they must be created *de novo*.

I have kept pretty closely in touch with the discussions of these matters during a good many years, and think it is safe to say that there has been more said about what kind of a head the public health agency should have than about the organization of the agency itself.

PLAN OF DISCUSSION

Deferring for the present the consideration of that matter, I desire to present the question of the organization. I wish first, however, to make it plain that I do not intend to present the matter from the point of view of any particular organization, sect or clique, either official or unofficial. I propose merely to outline a tentative enumeration of the *kind* of activities that might be embraced in the national health organization, to take them up seriatim and set forth to what extent they exist, how far existing agencies are capable of development, to what extent their transfer from their present location would be possible or desirable, and what new agencies would have to be created. I then propose to present the only two possible plans for the organization of the various activities into a practical administrative machine, and lastly, to discuss what sort of a head the whole organization should have.

I am aware, as already stated, that this is reversing the plan followed in most of the discussions of the subject, but I believe it is logically sounder to settle the question of the apex after the dimensions and character of the subjacent pyramid have been settled than to determine the character of the apex and then construct the pyramid to fit it.

Just here it may not be amiss to point out the chief difficulty that has confronted most of those who have undertaken to make detailed plans for a department or bureau of public health, and that is that very few of them have been familiar with the legal aspects of the case, of precedent, existing or former laws, the opinions of the comptroller or the decisions of the courts. Neither, as a rule, have they been familiar with governmental matters. In effect they have undertaken to make plans for an edifice without being familiar with either the inherent structural qualities of some of their materials, or the provisions of the building code under which they must be combined. I do not claim to be exempt from these difficulties myself, but twenty-two years close contact with many of them has given me a fair degree of familiarity with the subject, and I have therefore in the preparation of my plan avoided such difficulties, as far as I could, and endeavored to indicate what they were when I could not avoid them.

In the outline presented in the accompanying diagram I have embodied more or less the suggestions offered by various people at various times as to what should be represented in the new organization, notably those of Dr. Kober and Dr. Wiley before the Senate committee, but the arrangement is my own, the result of many years of practical experience with the advantages and defects of the existing public health agencies of the government.

REASONS FOR TWO GRAND DIVISIONS

In the accompanying diagram it will be noticed that there are two grand divisions—scientific and administrative. There are three reasons for making these two grand divisions.

First.—There are grave constitutional questions involved in administrative action by the government, in many public health matters, questions involving the "police power" and the like, which do not apply to the making of purely scientific investigations and the publication of the results. The latter may be clearly justified as necessary for the information of the government in order that it may intelligently regulate the sanitary aspects of interstate and foreign commerce, or for intelligent regulation of its own governmental agencies, or of areas under its jurisdiction. In organization, therefore, the two sides should be kept distinct in order that legislative action designed to promote the research side be not restricted by the necessity of avoiding constitutional restrictions on administrative encroachment on the powers reserved to the states.

Second.—This arrangement will facilitate the coordination of the commissioned organization of the Public Health and Marine-Hospital Service with the activities to be enlarged, transferred or created. Every impartial student of the subject knows that this service will be the largest single component of any new health organization, and the question has been how to retain the advantages afforded by the coherent, compact and disciplined administrative efficiency of that service, and at the same time secure the necessary flexibility of organization to provide for the utilization of a personnel drawn from a variety of other sources, especially in connection with research work. I do not for a minute mean that the personnel of the Public Health and Marine-Hospital Service shall be confined to the administrative side, or that the personnel drawn from other sources shall be confined to the research side; neither am I trying to champion the Public Health and Marine-Hospital Service under the pretense of an impartial discussion of the subject of the new organization. I only want to point out one of the advantages in keeping the natural grand divisions clearly in view when making legislative provision for the new organization.

Third.—The division follows the customary lines of governmental organization and will therefore promote efficiency.

EXPLANATION OF DIAGRAM

A. SCIENTIFIC SIDE. (FIRST GRAND DIVISION.)

I. Bureau (or Division) of Statistics and Reports.

(a) *Compilations.*

The compilation and publication of the mortality statistics of this country is now done by the Division of Vital Statistics of the Census Bureau, Department of the Interior. The current morbidity and mortality statistics concerning the so-called quarantinable diseases, cholera, plague, typhus fever, smallpox and yellow fever, of both this and foreign countries are

	(2) For State and Municipal Officers.		

compiled and published weekly by the Division of Statistics and Reports of the Public Health and Marine-Hospital Service, Treasury Department. The statistics of other infectious diseases, as tuberculosis, measles, typhoid and scarlet fever and diphtheria, are also collected from those states or municipalities which will supply them, and published weekly by the Public Health and Marine-Hospital Service, Treasury Department, together with the tabulated mortality reports of some ninety principal foreign cities, and untabulated mortality reports from a considerable additional number of foreign cities and countries.

Vital statistics are the foundation of scientific public health work, and they are equally essential for the analysis of census returns. On the other hand, international statistics are not properly a part of the census, and both the Census Office and the Public Health and Marine-Hospital Service rely on states and municipalities for their information, but of course the machinery of the Bureau of Vital Statistics is much more complete than that of the other service and its personnel is better trained in the interpretation of statistics on their social and economic sides, and to a lesser extent on their sanitary side. The question may therefore be stated thus: The census work would not be complete without the collection of vital statistics; scientific public health work cannot begin without access to compilation of vital statistics.

Fortunately figures are not like the fruit of scientific research. They can be collected by one agency and interpreted by another in so far as they apply to its own work. Whether then the Division of Vital Statistics should be transferred to the health organization, or whether it shall supply the latter with the results of its work, the mutual division of the publication to be determined by regulations, is not a very essential matter.

(b) Publications.

The existing publications of direct public health interest are the bulletins of the Hygienic Laboratory, the Public Health series of pamphlets, the Weekly Public Health Reports, and the Surgeon General's Annual Report, all issued by the Public Health and Marine-Hospital Service of the Treasury Department; some of the bulletins of the Bureau of Chemistry, Bureau of Animal Industry, Bureau of Plant Industry, and the nutrition investigations of the Experiment Stations, all of the Agricultural Department, and a few of the publications of the Department of Commerce and Labor—especially of the Bureau of Immigration.

One of the greatest fields of usefulness open to a national health agency is in the direction of publishing the results of its various investigations and activities by means of bulletins, reports, lectures, and the like. The enormous good done by the Department of Agriculture along these lines is well known. There may be legal objections to going into a state to do intrastate work, even for interstate purposes, but there can be no objection to the communication to state and local authorities by the government of the results of its own investigations. In so far as it may be deemed wise to transfer, in whole or in part, any of the activities of the last two named departments, of which I will speak later, their publications would logically simply go to swell the number, bulk and value of the first three publications, the research reports falling to the share of the laboratory bulletins, those of the other investigations to the public health series, and the statistical and other matters of immediate interest for national, state and municipal sanitarians to the weekly *Public Health*

Reports. The skeleton of the agency for publications may thus be said to exist already.

(c) *Library of Medicine and Surgery.*

This—known as the Surgeon General's Library—is now in the War Department, but its work has no inherent or essential connection with the work of the Army Medical Corps which now supplies the officers who have charge of its work. It is the great medical library of the country and should logically go into a national public health organization.

(d) *Climatology.*

This is of important public health interest but as the meteorologic data on which it rests are compiled by the Weather Bureau in the Department of Agriculture, it would seem expedient that the collection of the data be left as it is, their interpretation only becoming a duty of the national public health organization.

(e) *Advice to State and Local Authorities.*

As this will be principally by means of publications, and correspondence in explanation and amplification, of them, the work should belong to the Scientific Division.

II. Bureau (or Division) of Sanitary Research.

(a) *Laboratory Investigations.*

(1) BACTERIOLOGY AND (2) PATHOLOGY.

The bacteriology and pathology of public health interest is now done principally by the Division of Bacteriology and Pathology of the Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department, and the Bureau of Animal Industry of the Agricultural Department.

(3) PARASITOLOGY (to include entomology).

The work on these subjects of most importance from a public health point of view is now done by the Division of Zoology of the Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department, by the Division of Entomology, to some extent by the Bureau of Animal Industry, and to a less extent by the Bureau of Plant Industry, all of the Agricultural Department.

(4) PHYSIOLOGY.

There is no agency of the government now confined solely to the study of human physiology. Incidentally to the other work it is studied by some of the divisions of the Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department, the Food and Drug Laboratory of the Division of Chemistry, Agricultural Department, and by the Nutrition Experiments and Pharmacologic Laboratory of the same department.

(5.) BIOLOGY (to include control of vaccine and antitoxin production and nutrition experiments).

This also is studied incidentally as a part of the work of the Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department, the Bureau of Animal Industry, the Division of Entomology, Bureau of Plant Industry and Nutrition Experiments of the Agricultural Department. The nutrition work only in the latter, and the control of vaccine and antitoxin (by statute) only in the Hygienic Laboratory.

(6) CHEMISTRY.

General chemistry, organic and inorganic, purely as such, is now studied by express statutory direction in the Division of Chemistry, Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department, and in the Division of Pharmacology of the same. Chemistry as incidental to food and drug work, in the Division of Chemistry, also incidentally by the Bureau of Plant Industry, and to some extent in other divisions of the Agricultural Department; also in the Laboratory of the Bureau of Standards.

(7) PHARMACOLOGY.

In the Division of Pharmacology, Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department; in the pharmacological laboratories of the bureaus of Chemistry, Animal Industry and Plants Industry of the Department of Agriculture.

The agencies engaged on these branches (laboratory investigations) are so interrelated that the whole matter can best be discussed under one heading. It seems clear that in so far as any of the activities of the bureaus, divisions and laboratories mentioned can be disassociated from the work essential to the performance by the departments containing them of their own particular duties, they should be, in a public health organization. In this category are all the divisions of the Hygienic Laboratory, Public Health and Marine-Hospital Service, Treasury Department, the nutrition experiments and the pharmacologic laboratories of the Bureaus of Plant Industry, Animal Industry and Chemistry of the Agricultural Department, and probably the Purification of Water Laboratory of the Bureau of Plant Industry. The Bureau of Entomology may be in this class but probably its major work is too intimately connected with the Agricultural Department to permit of its transfer.

DIFFICULTIES IN ARRANGING TRANSFER OF SOME OF THE LABORATORY INVESTIGATIONS

When we come to the chemical, biologic, pathologic, physiologic and bacteriologic work of the Agricultural Department bureaus and divisions the subject is most difficult. Much of the work done in these lines by these bureaus and divisions is merely incidental to their real function, and yet is inseparable from it, just as the production of by-products in a manufacturing plant may be of little moment to the business as a whole, and still the business cannot be conducted without developing them. Professor Wiley says that some of the "activities" could be transferred, but does not go into detail. The plain fact is that the problem is one that no congressional committee, or no one person outside of the committee, whether lay or medical, is competent to solve. The reason for this is that the question is neither a wholly legal one nor a wholly scientific one. In a sense it is one of "departmental engineering;" one of deciding just which cogs, wheels and pinions of the department machine can be removed without impairing the efficiency of the machinery or necessitating an expenditure, immediate or future, as great as the saving sought to be secured by the transfer of the parts to some other machine. For the present, however, it may be said that the main controversy rages around the question of what shall be the home of the "pure food" work and the inspection work of the Bureau of Animal Industry of the Agricultural Department, and the nub of the whole matter is whether these activities are "commercial" or "public health" matters. If the so-called "pure food" law is, as one of the most eminent sanitarians in the United States, the late Professor Harrington, has said it was, merely an act to prevent fraud and misbranding, conferring protection to public health as an incident to its execution and not as the object of its enactment, then it belongs where it is; but if it be a public health matter, either primarily or because of the resulting advantages of its enforcement, it should be in the public health organization. The same is true of the activities of the Bureau of

Animal Industry of the Department of Agriculture. One or more witnesses advance the idea that while the inspection, shipping, etc., of live animals was a "commerce" matter and as such should be under the Department of Agriculture, that the slaughtering and post-mortem inspections should be under the public health organization; in other words, that a live steer is an object of commerce, but that a dead one is not. The work of the Bureau of Animal Industry is of incalculable importance to public health, but so it is to the purely agricultural and commercial interests. How shall the dispute be decided? I think there is a way to settle these questions, but it should be properly taken up when we come to the question of legislation.

(b) *Field Investigations.*

(1) *EPIDEMIOLOGY.*

The work done on this subject is practically confined to certain field investigations made in this country by the Hygienic Laboratory of the Public Health and Marine-Hospital Service, Treasury Department, under the direction of the Division of Sanitary Research of that Service, and in the Philippines by the Director of Health of the Insular Government, who is detailed from the Public Health and Marine-Hospital Service, and by the Army Medical Corps as incidental to their duty in the islands.

The general verdict being that the army work must be kept out of the national public health organization, all that would be necessary for the development of this branch of work would be to extend the scope of the authority, at present much restricted, under which the work is now done.

(2) *HOUSING AND SOCIAL CONDITIONS.*

(3) *WORKSHOP, MINES AND INDUSTRIAL CONDITIONS.*

There is considerable work done at present in the direction of investigating the conditions enumerated but it is incidental to the work of several bureaus and divisions of the Department of Commerce and Labor rather than by explicit statutory direction. The Bureau of Mines, Department of the Interior, has been recently created by statute, but it is not known at this time what, if anything, will be done in the nature of sanitary investigation.

There was more or less said at the hearings, and a great deal has been written, about the necessity of putting this work under the jurisdiction of the national public health organization, and I have therefore included the titles among the activities enumerated as proper to that organization, but as I cannot see how administrative work along those lines can be legally done, I have placed the items under the group of subjects which the government may investigate for its own purpose, the results being then available for general information. If the work be done it must be done either by machinery created *de novo* for that purpose in the public health organization by transferring the activities now in the Department of Commerce and Labor to the health organization, or by the Department of Commerce and Labor as at present. The last plan would be the easiest, the second the most difficult, and the first would give the best results, though of course it would produce some duplication of work.

(4) *STUDY OF THE DISPOSAL OF SEWAGE AND WASTES.*

Some work has been done along this line by the Division of Sanitary Research, Public Health and Marine-Hospital Service, Treasury Department, directly, and some indirectly by officers serving on boards such as the Lake Michigan Water Commission; some by

the Purification of Water Laboratory and the Bureau of Plant Industry, Agricultural Department, and very extensive sanitary surveys have been made by the Geological Survey.

It would seem that the Purification of Water Laboratory should come into the public health agency and that means be provided for continuing the present work of the Division of Sanitary Research as above.

LEGAL WARRANT FOR THE STUDY OF THE DISPOSAL OF WASTES

The relations of this subject to the preservation of the navigability of streams, to the preservation of fisheries in waters under the jurisdiction of the general government and to the health of those engaged in interstate water-borne commerce, are so important that it is clearly one of the things about which there would seem no ground for objection from those who question the legality of some of the other work proposed by the advocates of an enlarged public health organization.

(c) *School of Applied Hygiene.*

(1) *FOR INSTRUCTION OF THE PERSONNEL OF THE PUBLIC HEALTH ORGANIZATION.*

(2) *FOR THE INSTRUCTION OF STATE AND MUNICIPAL HEALTH OFFICERS.*

The Public Health and Marine-Hospital Service, Treasury Department, now sends its officers to the Hygienic Laboratory under its own jurisdiction and admits representatives of state boards of health to take this laboratory course.

This has been the practice for a long time and the results have been good, but very limited. The most vital need in a public health way in this country is a supply of men trained for the work of local, county and state health officers. State and preventive medicine is a profession in itself and we can only advance in local health administration as we give appropriate recognition to that fact. If we had local health officers in the villages and rural districts of this country comparable to those they have in England, for instance, the public health problems would be on the road to solution, and there would be little for a national public health organization to do except to make scientific investigations and act as a sort of clearing house for the state boards, but it will be many, many years before that time comes, if it can ever come under our system of government, and in the meantime the interests of the country can be served in no better way than by providing the means by which the state, county, town and village health officers can be instructed in the technical side of their duties. Every man so trained will become a focus of active sanitary improvement within a certain area, and directly as these areas increase in size and number will those conditions disappear whose existence has been the basic cause of most of the agitation for the performance by the general government of many things that should be done by the states. We have been teaching the farmer how to double the number of bushels of grain he can raise to the acre, and why should we not instruct the farmer's local health officer how to cut in half the number of tombstones in the farmer's graveyard? This would have nothing to do with cults or systems of medicine, or the teaching of medical practice. The work of the health officer stops where the practice of medicine begins. He does not treat the sick, he prevents sickness.

How can the government legally maintain a school of applied hygiene to which the men of the state boards of health can come? For of course there is no dispute as to its right to maintain a school for the instruction of its own officers. It is by the same right that it subsidizes sectarian medical schools in Washington to which all may come, but fortunately there is a more direct precedent as in the case of the army schools at Leavenworth, Fort Riley and Fort Monroe for the instruction of its own officers, to which are admitted such officers of state troops as desire instruction. We already have part of the plant and the skeleton of the organization for this work. Whatever this Congress does in public health legislation it can do no one thing of greater potential good than to provide the means by which this work can grow in scope and efficiency.

B. ADMINISTRATIVE SIDE (SECOND GRAND DIVISION).

I. Bureau (or Division) of Personnel and Accounts.

- (a) *Mails, Files, etc.*
- (b) *Personnel.*
- (c) *Accounts.*

This first division of the administrative side of the national health agency follows the existing plan of the organization in the Bureau of the Public Health and Marine-Hospital Service of the Treasury Department.

It is essential for efficient executive administration that all the work covered by the subheads of this section be administered in one part of the organization. Through this division will pass all the correspondence, and in it will be kept all the records relating to correspondence, and to the personnel composing the various bureaus or divisions of the organization. In it will be handled all the accounts and records pertaining to them, and by it will be transacted all the business which the public health agency will conduct with the other executive departments of the government. All matters relating to personnel, employment, appointments, leaves of absence and the like, will be handled by this division.

This does not mean, of course, that correspondence cannot originate in other bureaus, scientific or administrative; it simply means that all incoming mail will be received and distributed through this division, and all outgoing mail, after being signed by the particular administrative officer charged with the authority to sign for the bureau or division in which the letter originated, will pass out through this Division of Personnel and Accounts after being entered, etc. Without such a division it would be impossible for the executive head of the entire public health service to keep in touch with what had originated, or what had been received by any particular bureau or division of the organization. The organization for this purpose now existing in the Public Health and Marine-Hospital Service of the Treasury Department is capable of being readily expanded to any extent that may be desired.

II. Bureau (or Division) of Quarantine and Immigration.

(a) *Quarantine.*

(1) *DOMESTIC.*

(2) *FOREIGN AND INSULAR.*

All quarantine functions of the government are now entrusted to the Public Health and Marine-Hospital Service of the Treasury Department, and for

the purpose of carrying on the work that service contains two divisions: 1, the Domestic Quarantine, and 2, the Foreign and Insular Quarantine.

This division is purely one of convenience for the administration within the bureau. Under these divisions the service operates all the maritime quarantine stations of the Pacific coast and practically all of the Atlantic coast except that controlling the two great ports of Boston and New York. The law authorizes the government to take over the control of any state quarantine when the authorities of the state in question request it to do so, and provides for the compensation of the state for the plant turned over. In a few instances inspection stations are maintained by cities, although the government may maintain a station covering the navigable water leading to that city. In addition the government, through the Public Health and Marine-Hospital Service, has charge of the maritime quarantine of the Isthmus of Panama, in the Hawaiian Islands, in the Philippines and in Porto Rico, and maintains a considerable number of inspection stations in different parts of the world for the inspection and treatment, disinfection, etc., of vessels bound for the United States. There are forty-four quarantine stations on the coast of the United States operated by the Public Health and Marine-Hospital Service; twenty-seven insular quarantine and inspection stations, and thirty-three inspection stations in foreign ports. In addition to this the Domestic Quarantine Division has charge of all questions which arise in connection with the interstate transmission of disease and the management of epidemics.

(b) *Immigration.*

The medical inspection of all immigrants arriving in this country is now made by the medical officers of the Public Health and Marine-Hospital Service of the Treasury Department, who are detailed for that purpose. This is at present done under the immediate control of the Division of Domestic Quarantine as above. The officers detailed for this duty receive their orders from the Public Health and Marine-Hospital Service, and are paid through that service, but out of the funds of the Immigration Service, Department of Commerce and Labor. They report directly to the Division of Domestic Quarantine, Public Health and Marine-Hospital Service, and are subject to the regulations of that service. This system has been in existence twenty years and has been found to be very satisfactory. In addition, at times when the importation of such diseases as cholera, plague, etc., are especially to be feared, officers are stationed at foreign ports, attached to the consulates, for the purpose of inspecting immigrants who are about to embark for the United States, and a similar inspection is maintained at all times at such places as Yokohama, Hong Kong, Amoy and Naples.

(c) *International Sanitary Relations.*

At present the government maintains international sanitary relations under the International Sanitary Convention of Paris, of which the United States is one of the ratifying powers, and through the International Bureau of American Republics. The relations with European countries are maintained through the International Bureau of Public Hygiene of Paris, established under Article 181 of the above mentioned convention, in which bureau the United States government is represented by an officer of the Public Health and Marine-Hospital Service delegated for that purpose. The international relations with Mexico and the Central and South American states are maintained by means of international sanitary conventions which have been held from time to time under the auspices of the International Sanitary

Bureau of American Republics, of which convention the Surgeon General of the Public Health and Marine-Hospital Service of the Treasury Department is the chairman.

At present the international relations are still very largely in a formative state, but the rapid progress being made in the matter will make it necessary very soon that provision be made in the national health organization for a subdivision to handle the questions arising in connection with international relations, and when such a division or subdivision is established it would be logically located in the bureau or Division of Quarantine and Immigration.

(d) *Management of Epidemics.*

As already stated, the management of epidemics is at present in charge of the Division of Domestic Quarantine of the Public Health and Marine-Hospital Service of the Treasury Department, and would be naturally continued in any enlarged public health organization in that division, as a subdivision of the Bureau of Quarantine and Immigration.

(c) *Philippines and Isthmus.*

As already explained, the maritime quarantine in the Philippines and on the Isthmus is under the direction of the Division of Foreign and Insular Quarantine of the Public Health and Marine-Hospital Service of the Treasury Department, but in addition, there are very important public health functions performed by the same division in connection with the government of the Philippine Islands. The public health work there, as distinct from the maritime quarantine, is under the control of the Insular Government through an officer known as the Director of Public Health. At the present time this position is filled by an officer detailed from the Public Health and Marine-Hospital Service of the Treasury Department who combines with his function of Director of Health under the Insular Government, the position of Chief Quarantine Officer for the Philippines under the Public Health and Marine-Hospital Service of the Treasury Department. This arrangement is at present not a matter of law but is subject to change by the President.

In any new or expanded national public health agency the functions described above under the second heading of the administrative side (Quarantine, Immigration, International, Sanitary Relations, Managements of Epidemics, and Philippines and Isthmus,) would necessarily have to be carried on exactly as at present. As far as I can recall, none of the plans which have been suggested for such a new or expanded organization have suggested the addition of any functions in regard to matters connected with quarantine, immigration, international sanitary relations, management of epidemics, or the Philippines and Isthmus, and as the present arrangement works satisfactorily and is capable of future expansion by presidential regulations, and without the need of special legislation, it does not seem to be necessary to make any suggestions in connection with it.

III. Bureau (or Division) of Governmental Hospitals.

(a) *U. S. Marine Hospitals.*

- (1) MARINE HOSPITALS AND DISPENSARIES.
- (2) MEDICAL OFFICERS FOR REVENUE CUTTERS.
- (3) PHYSICAL EXAMINATION FOR ENLISTMENT, REVENUE CUTTER SERVICE.
- (4) EXAMINATION OF SIGHT AND HEARING OF PILOTS AND MASTERS.

- (5) PHYSICAL EXAMINATION FOR LIFE SAVING SERVICE.
- (6) SERVICE TO BE RENDERED IN TIME OF WAR.

The management of the U. S. Marine Hospitals is now under the charge of the Division of Marine Hospitals and Relief, Public Health and Marine-Hospital Service of the Treasury Department, and this division also has charge of the other five classes of work mentioned above. Through it are provided the medical officers for the Training School of the Revenue Cutter Service and those who serve on the larger seagoing cutters. At the present time about 10 per cent. of the officers of the lower two grades of the Public Health and Marine-Hospital Service are serving at sea under these details. In addition the service makes all the physical examinations for enlistments in the Revenue Cutter Service and provides the medical officer for examining and retiring boards of that service. The examinations as to color sense, acuteness of vision and hearing, which are now prescribed by law for all applicants for license as masters or pilots of vessels, are conducted by this service, as also are the annual physical examinations made for the crews of the Life Saving Service. In the marine hospitals are cared for the sick of the merchant marine, the Revenue Cutter Service, the Life Saving Service, the civilian crews of the vessels of the Quartermaster's and Engineer's Departments of the Army and of naval colliers, officers and crews of the vessels of the Coast and Geodetic Survey and Mississippi River Commission. In addition the hospitals care for foreign seamen on the request and at the expense of the government to which they belong. The law also provides that in time of war the president can make use of the commissioned medical officers of the Public Health and Marine-Hospital Service of the Treasury Department as he may determine, and such officers have rendered services of this character in action during the Spanish War, and in the Philippine Insurrection.

As it is presumed that the functions outlined above will continue to be performed in the same manner under any new or expanded public health organization, it does not seem necessary to make any suggestions in connection therewith.

(b) *U. S. Hospital and Baths, Hot Springs, Ark.*

The present situation at the Hot Springs of Arkansas is that the United States Hospital there is maintained for the treatment of officers and men of the Army and Navy, and the officers of the Public Health and Marine-Hospital Service, and is under the control of the War Department. Some of the bills now pending propose to transfer the conduct of this hospital to the new or expanded public health organization, and if such action be taken, the management of the institution would logically come under the bureau or division charged with the operation of similar government institutions. I have therefore placed it under this heading.

(c) *Medical Service, U. S. Soldiers' Homes.*

At present the medical service at the Soldiers' Homes is under the control of the Department of the Interior, but if transferred to the control of the new or expanded public health agency would naturally come under the jurisdiction of the bureau or division under which I have placed it.

(d) *Hospitals for Immigrants.*

At present the hospitals for immigrants are under the control of the Bureau of Immigration, Department of Commerce and Labor, but the medical officers are detailed from the Public Health and Marine-Hospital Service of the Treasury Department, so that they too, if transferred as suggested in some of the bills, would be placed under the bureau or division which we are considering.

(d) *Government Hospital for the Insane.*

The management of the Government Hospital for the Insane is at present vested in the Board of Trustees and is under the direct control of Congress.

Whether or not the various institutions enumerated under the last four subheads (*b*, *c*, *d*, and *e*) should be transferred to the control of the national public health organization is a grave question. The Government Hospital for the Insane is practically the local insane institution for the District of Columbia, although it also cares for the insane of the Army and Navy, and the beneficiaries of the Public Health and Marine-Hospital Service. I am unable to express an opinion as to whether it would be best to leave matters as they are, or transfer this institution to the public health organization. The same is true in regard to the Hot Springs Hospital and the soldiers homes. I think, however, that as the medical inspection and treatment of immigrants is now done by the Public Health and Marine-Hospital Service it would be logical to transfer the management of the hospitals themselves to that service, or rather to the national public health organization of which the Public Health and Marine-Hospital Service will be a part. The present arrangement, it is true, works fairly well, but it certainly would seem desirable that the general management of a hospital should be under the same jurisdiction as that which supplies the medical service.

IV. Bureau (or Division) of Applied Sanitation and Sanitary Engineering.

(a) Interstate Sanitation.

(1) WATER COURSES.

Except for the extensive surveys made by the Geological Survey the only work done in this connection at the present time is indirect, as detailing officers of the Public Health and Marine-Hospital Service, Treasury Department, for service on bodies such as the Lake Michigan Water Commission, or incidental to investigations by the same organization of typhoid outbreaks, or by the Hygienic Laboratory of the same service as in the Sanitary Survey of the Potomac Watershed, and in daily bacteriologic examinations for the Washington filtration plant.

(2) RAILWAYS.

Except in connection with the management of epidemics by the Division of Domestic Quarantine, Public Health and Marine-Hospital Service, Treasury Department, the government exercises no control over the sanitation of railways.

(3) SHIPPING.

In times of threatened invasion by such diseases as cholera the Division of Foreign Quarantine, Public Health and Marine-Hospital Service, Treasury Department, has charge of the sanitary conditions of vessels sailing from foreign ports for this country, and in times of epidemics the Division of Domestic Quarantine of the same service, assumes charge of interstate shipping. The general control of regulating the sanitary conditions on vessels, air, space, ventilation, food and water supply, character and amount of medical attendance, medical supplies, etc., is under the charge of the Bureau of Navigation of the Department of Commerce and Labor.

How far the government may go in the direction of controlling the sanitary conditions in navigable interstate lakes and streams is a legal question. Under the notes in connection with the subheading "Disposal of Wastes" I have pointed out several reasons which seem to me to justify the opinion that contamination of navigable waters is a proper matter for government regulation, and it is not necessary to repeat them here. Certainly it does not seem reasonable that on the Great Lakes, for example, the general government should prevent the states which draw their drinking water from the lakes from exercising any control over the contamination of those waters by shipping, and yet be power-

less itself to take steps for the prevention of the contamination. With this in view I have included water-courses as a proper matter to be embraced in the plan for a national public health organization. It must be admitted, however, that in the case of non-navigable interstate waters the matter can hardly be one for regulation by the general government. Fortunately the Constitution, while preventing direct relief by the government in such cases, has provided a way for adjusting the matter by a congressionally sanctioned agreement between the states concerned, and the court decisions in the Georgia-Tennessee copper fumes case have indicated how a state may force another to either cease polluting a mutual water supply or else join in an agreement for the regulation of the matter. As to the right to regulate the sanitary conditions on interstate railways, there does not seem to be any dispute. The Act of 1893 authorizes the Secretary of the Treasury to make rules and regulations necessary "to prevent the introduction of infectious and contagious diseases from one state or territory into another state or territory" but imposes no penalty. It would seem that all that is needed is the rectifying of this omission to give a national public health organization all the law it needs. In the matter of shipping, it seems clear that execution of the portions of the "Passenger Act" which relate to sanitary matters on vessels should be taken out of the jurisdiction of the Bureau of Navigation, Department of Commerce and Labor, and placed under the control of the national public health organization.

(b) Public Buildings.

There is at present no central agency in charge of the sanitary condition of Public Buildings. The Division of Sanitary Research, Public Health and Marine-Hospital Service, Treasury Department, has done some work in connection with the ventilation of the Capitol, and has investigated by a commission the conditions as to tuberculosis in the buildings of the executive departments in Washington, but the tendency has been for each department, or in the case of the very large buildings, the superintendent or custodian, to look after its own sanitary affairs.

It would seem to be desirable that the national public health organization should have at least advisory control of the sanitary problems which arise in connection with the large public buildings—possibly by means of a system of inspections; possibly by merely providing a method by which the superintendent or custodian could apply to the national public health organization for advice, or expert assistance. I doubt very much if it be expedient at present to try to do more than this. Every executive department will have a natural hesitancy in surrendering any actual control in its own territory, while they might be glad to get advice on occasions. In time the control of the sanitation of government buildings should be placed under the control of the public health organization.

(c) Assistance to State and Local Authorities.

Assistance in public health matters other than by publications, correspondence or laboratory research has, as far as I am aware, been given very rarely, if ever, by national agencies to the public health authorities of states and municipalities, except by the bureau of Animal Industry, Agricultural Department, and by various divisions of the Public Health and Marine-Hospital Service of the Treasury Department. The former agency had done a great deal of field work in aid of states, as, for example, tuberculin testing of dairy cattle destined for particular states, or in investigating outbreaks of animal diseases for.

or in cooperation with, state authorities, the most extensive work being in connection with Texas cattle-fever. The work of the Public Health and Marine-Hospital Service along these lines has been very extensive in the direction of assuming direct charge of local epidemics, and by taking up, at the request of state or local authorities, the field investigation of some particular condition. The work along the latter lines has been, of late, especially extensive.

OMISSION OF CERTAIN ACTIVITIES

In the outline given for the organization of a new or expanded public health organization I have purposely omitted, for reasons given below, a great many of the things which have been mentioned in the hearings and discussions as properly within the scope of such an organization, and included therein by the terms of some of the pending measures, as: education, child investigation, medical service of Indian reservations, etc.; and some, such as the establishment of biologic standards, the study of venereal prophylaxis, and the like, because putting them in the law is equivalent to directing that some of the divisions of the organization shall study the things they would be created to study, and furthermore those who are to be in charge of the work to be done should be given an opportunity to develop it along the lines which experience may prove to be best fitted to secure a coherent and logical plan of advancement and *pari passu* with the training and development of the necessary personnel. To prescribe too minutely the subjects for investigation and control will immediately result in an uneven and unbalanced development. Education, child study and the like I have omitted because I have tried to keep in view throughout, the fundamental idea that the law creating the new or expanded public health organization should be drawn in such a way as to avoid as far as possible raising the issue of interference with the powers reserved to the states, and so I have tried to keep pretty close to the lines of precedent in public health legislation. It would be most unfortunate to have some important portion of the new law promptly set aside by the courts. When the new organization is once firmly established and functioning it can be cautiously expanded by amendments which, if found unconstitutional, could be dropped without damaging the legal foundations of the main structure.

CONSTRUCTION OF NEW ORGANIZATION

Coming now to the question of how the machinery of the new organization shall be constructed to secure the performance of the duties grouped under the above suggested plan, it would appear that only two plans of organization are possible; to consolidate the activities, whether resulting from transfer or creation, with the Public Health and Marine-Hospital Service under some form of departmental or bureau organization, or, to consolidate such transferred or created activities into the Public Health and Marine Hospital-Service under either the present form of control or under some new arrangement.

THE QUESTION OF THE HEAD

This brings us to the question of the head. Four plans are possible:

1. A cabinet officer presiding over a new executive department.
2. An assistant secretary reporting to the head of one of the existing departments

3. A Director-General of Public Health, or a Commissioner of Public Health, of permanent or semipermanent tenure of office presiding over an independent organization and with a status similar to that of the former Commissioner of Agriculture, and reporting directly to the President.
4. A permanent, or semi-permanent, director-general or similar official reporting directly to the cabinet minister at the head of one of the existing executive departments.

ADVANTAGES AND DISADVANTAGES OF EACH PLAN

The first plan is the one about which most has been said, and beyond doubt a just appreciation of the magnitude of the interests involved must lead to the conclusion that these interests are worthy of having a department. Unfortunately there seems to be much opposition in administrative and congressional circles to any increase in the number of the executive departments. The possibilities of overcoming this opposition, and the methods by which it might be overcome, are outside of the scope of this paper, so I shall only briefly mention the advantages and disadvantages of this plan. The principal advantages would be that a departmental organization would give a status to its chief that would enormously increase his prestige with Congress, and his influence and authority in dealing with international and interstate questions; that it would considerably simplify some of the questions arising in connection with the transfer from other departments of the larger activities which have been the subjects of discussion, since there would be no questions of precedence to settle, and would enable the department head to deal directly with other department heads in obtaining data resulting from the researches of agencies working in these departments, in securing cooperation in the larger administrative questions, and in facilitating such joint activities—as for instance the immigration inspections. The disadvantage is that the choice of the department head would not improbably be influenced by geographic or political considerations rather than by the qualifications required of a man who would preside over a semi-scientific department.

The second plan, an assistant secretary reporting to the head of one of the existing departments, seems to be open to some very serious objections. The assistant secretary would have to submit questions of policy, legislation or appropriations to the attention of the President and Congress through the intermediary of a department head who might, through lack of either knowledge or sympathy, fail to present them to the President and to Congress in a manner best calculated to secure the ends in view. Whatever department were chosen, the work for the prosecution of which the department in question was created, and for his fitness in administering which the department head had been chosen, would naturally engage most of that chief's attention and lead, unintentionally, perhaps, but still inevitably, to a neglect of the public health interests. If, on the contrary, the department chief took an active interest in the public health work it is exceedingly improbable that he would have the training and knowledge necessary to make the results of his interest and interference advantageous. Moreover, it would involve the possible danger that external interests, political or commercial, would exert pressure on the departmental chief that might be exceedingly disadvantageous to the interests of public health efficiency. Furthermore, it would involve a good deal of lost motion in the machinery of the public health organization by the interposition of an additional

gearing between the machine, as such, and the source of its power in presidential and congressional support.

The third plan seems to be, by all means, the one to be followed, but unfortunately is opposed to congressional policy, which is strongly against creating agencies independent of one of the executive departments. It would avoid all the disadvantages outlined in the discussion of the first and second plans, and would possess some advantages of its own, the chief of which would be that it would promote efficiency by definitely fixing the personal responsibility for it. If the plan of organization is followed by which the transferred and newly created agencies are consolidated *with* the Public Health and Marine-Hospital Service, it would, by the independence and dignity of the position of the director or commissioner, attract a better equipped class of candidates than a subordinate assistant secretaryship of anomalous position, and render it much less likely to be the reward for political services. If, on the other hand, the plan is adopted of consolidating the transferred and newly created agencies *into* the Public Health and Marine-Hospital Service the Surgeon-General of that service will either fill the position of director, or commissioner, himself, *ex-officio*, or will be the executive officer of the organization, serving under the director or commissioner, very much as the Chief of Staff serves under the Secretary of War, and in either case the advantage of long tenure of office for the executive will be added to the advantages above enumerated as inherent to the third plan.

As already stated, I am of the opinion that the third plan suggested is the best at the present time, but it is directly against the pretty general trend of congressional policy and probably would arouse as much, or even more, opposition than the establishment of a new department. For this reason I offer the fourth plan of organization. It would be the easiest from a legislative point of view, since it would be practically an amplification of the existing relations of the Public Health and Marine-Hospital Service with its departmental chief, but with the very important difference that its head would by law report directly to the head of the Department concerned, and not, as often has been the case in the past, to a second or third assistant secretary.

The permanency of tenure would eliminate most of the objections inherent to the plan of having an assistant secretary, but the difficult personal equations in handling the chiefs transferred along with activities under their control in existing departments would remain to be solved, and undoubtedly this form of organization would not satisfy many who are actively engaged in the present agitation for increase in the national public health activities.

SUGGESTIONS AS TO DRAFTING BILL

In conclusion, a few suggestions are offered as to the general plan to be followed in drawing a bill designed to embody in law the plan for such an organization as I have outlined:

First, the law should be as brief as possible, and should be confined to the declaration of certain basic legislative intentions, leaving the details to be arranged by regulations to be promulgated by the President. Such expression of legislative intentions should include: (a) Provision for the creation of a department, bureau or service, as may be determined on, with a declaration of the fundamental principles in accordance with which the new department, bureau or service is to be organ-

ized; i. e., either for a consolidation of the activities to be transferred or created with, or into, the Public Health and Marine-Hospital Service; (b) provision for the head of the new department, bureau or service, whom he shall be, how he shall be appointed, his tenure of office and compensation; (c) an enumeration in the fewest possible words of the duties to be performed, as, for instance, "the investigation and management of all matters relating to the public health as now or hereafter authorized by law or by this act"; (d) provision for the continuance of the personnel of the various existing agencies affected, for their salaries, allowances, etc., and provision for the personnel of any newly created agencies; (e) authorization for the necessary clerks, etc., without stating salaries or numbers; (f) continuance in general terms to the various agencies of the special authorities and duties now vested in them by law; (g) continuance of the availability of all appropriations, funds, etc.

Second, it should for the present only transfer or consolidate existing or new agencies that are not the subjects of serious dispute on grounds of either expediency or constitutionality. The Pharmacological Laboratories of the Bureau of Chemistry, Animal Industry and Plant Industry, Agricultural Department,¹ and the Library of Medicine and Surgery, War Department, are illustrations of the first class, and the study of the disposal of wastes with reference to their effects on interstate, water borne commerce and the health of those engaged therein, is an illustration of the second class.

Third, in order to provide for the question of existing activities, the expediency of transferring which is the subject of much dispute, as for example, certain parts of the Bureau of Animal Industry, Treasury Department, a provision should be inserted authorizing such transfers within one year by Presidential order and providing for a commission or committee of departmental chiefs, or delegated subordinates, who shall advise the President of their findings after investigating each case referred to them, but whose advice shall not be binding on him. The law creating the Department of Commerce and Labor contains a provision somewhat similar to this, but if in the case under consideration this is thought to savor too much of the delegation of legislative authority, the President might merely report his findings for the approval of Congress. All this sounds reasonably simple but it will involve a careful study of a large number of existing laws and no little legislative ingenuity to secure the results wished without the loss of something desirable.

There is much diversity of opinion as to the expediency of having an advisory board associated in any way with the management of the new agency. It is urged that it would strengthen the hands of the director or commissioner in public estimation if he had the support of a board of distinguished and disinterested advisors of national reputation, and perhaps it would, if he had it; but suppose that for reasons political, professional or personal, the board were not disinterested? On this point I venture to obtrude my personal opinion that no board should be given authority to meddle in any way with the management of the organization as a whole.

One more expression of opinion I desire to make, concerns, in general terms, the character of the activities to be transferred to the new agency. No activity should, for the present, be transferred whose work is of such a

1. See testimony of Dr. Wiley, p. 110, Senate Hearings on S-6049.

nature that its incorporation in a national public health organization will lead at once to the concentration on that agency, its personnel and its work, of the interested attention of powerful commercial and political interests. No matter how great the economic advantages resulting from public health work, nor to what extent it is clothed for constitutional reasons in the garb of commercial justification, the fact remains that its real objects are altruistic and humanitarian, and with these the politics of personal interest will not mix, though they may discolor them.

In conclusion I deem it proper to state that this article is in no sense inspired by Surgeon-General Wyman or to be construed as an expression of his opinions. It has not been submitted to him, nor has he been informed of its contents. It owes its publication simply to a personal desire to provide a basis for a discussion of a question that is of vital interest to the public and fundamental to the health and lives of the people of the United States.

EXTRACAPSULAR FIXATION OF THE MOVABLE KIDNEY*

CHARLES A. L. REED, M.D.
CINCINNATI

The word "extracapsular" is used in the title of this paper to imply fixation of the kidney by a method entirely external to the tunica fibrosa as distinguished from any method that implies either invasion of that tunic or surgical injury to the kidney itself.

The further significance of the term as it is here used may be made clear by a brief description of the essential features of the operative procedure that I have employed for the last several years—indeed, since 1904—for the anchorage of the pathologically movable kidney,¹ as follows:

TECHNIC OF EXTRACAPSULAR NEPHROPEXY

1. The patient is placed in the classical position on the well side with a firm pad, preferably pneumatic, under the same side. The equally classic incision about 1 cm. below the costal margin and about 10 cm. in extent is made obliquely downward and forward. This dissection is carried through the wall by cutting with the exception that, to the extent that may be found practicable in each individual case, the obliquus externus, the obliquus internus and the transversus abdominis muscles are separated and drawn apart by the finger rather than divided by the knife. In this way the capsula adiposa of the kidney is reached.

2. The capsula adiposa is a most important structure in my procedure, and the very first point that I wish to emphasize is that extreme care must be taken to separate it from its relations to the abdominal wall, to the extent that such relations may have survived the displacement. Care must be taken not to separate the capsula adiposa from the tunica fibrosa.

3. The kidney with its capsula adiposa attached to it is then lifted to the surface. In carrying out this manipulation it may be and generally is necessary first to deliver the upper pole of the organ through the operation wound, for reasons that I shall later explain.

4. The next step in the operation consists in wiping away the globular fat, much or little, from the con-

nective tissue stroma of the capsula adiposa. This stroma, likewise important in this procedure, will be found arranged in very distinct and essentially parallel striae extending obliquely downward and forward from the lower pole of the kidney. The manipulation of wiping the fat from its meshes is best carried out by the use of gauze, care being taken not to separate these striae from their attachment to the tunica fibrosa.

5. Gauze is now likewise employed to apply vigorous friction to the tunica fibrosa in its upper zone where the capsula adiposa but rarely invests it; but if it does the fat should be wiped away if possible without disturbing the attachments of its basic connective tissue striae. This friction to the tunica fibrosa should be continued until the upper zone shows small punctate hemorrhages over its entire area.

6. The kidney is now left for a few moments while any remnant of the capsula adiposa that may have been left adherent to the abdominal wall is entirely wiped away with gauze.

7. A nest—*nidus renalis*—free from fat—having thus been secured, the kidney is slipped back as nearly in *situ naturalis* as it will go without force.

8. The connective tissue striae of the capsula adiposa are then divided transversely at a distance of from 1 cm. to 2 cm. from the lower pole of the kidney. The stump thus formed on the renal side is stitched by chromicized catgut to the inner surface of the upper margin of the operation wound while the lower stump is similarly attached to the inner surface of the lower margin of the operation wound.

9. The operation wound itself is then entirely closed by laminated sutures. Drainage, being unnecessary, is, of course, not employed.

In explanation of the various steps that I have described, more particularly those that are peculiar to this procedure, I beg to offer a few observations:

THE CAPSULA ADIPOSA AND ITS CONNECTIVE TISSUE STRIAE

The connective striae of the capsula adiposa, so essential to this procedure, require a few words of explanation, particularly as they, in an aggregate sense, and as an anatomic structure have so far very generally escaped recognition as being of practical importance. In my previous published remarks² on this structure—I have come to recognize these striae as an anatomic element—I stated that when I first noticed it I thought it was adventitious, and probably, of inflammatory origin and that I had used it because it was convenient and seemed to lend itself to unipolar fixation.

It now seems, from a recent somewhat exhaustive research of the literature, that my experience was not singular. Thus Hahn,³ whose observation extends back to his inauguration of the practice of kidney fixation in 1881, says that "fibers run from the tunica fibrosa in front and behind to the subperitoneal fascia." Newman, of Glasgow observes⁴ that "frequently in long-standing cases the fat becomes infiltrated with connective tissue, making it tough and fibrous and when this altered capsule is stitched to the parietes the kidney can be maintained in its position without suturing the organ itself." Carwardine, of Bristol, says:⁵ "It is common in cases of wandering kidney to meet with strong fibrous bands some of which require scissors or scalpel for their divi-

in some cases becomes subnormal, in others stands around 100 F.; in a few runs high. Vomiting with acetone odor of breath occurs in a good proportion and is absent in others. The urine is limpid and free. Albumin has been present in some and absent in others of the few cases from which urine could be obtained. Urine from three cases was submitted to chemists for nitrogen estimation, and in each instance the report was that the ammonia nitrogen was high. Jaundice was absent in every case.

During the period of labored breathing the breath feels cold to the hand held in front of the nostrils. This has been interpreted, whether rightly or wrongly, to mean volatile substances thrown out in the respired air. During this period of labored breathing, too, soot, in our locality, lines the interior of the nostrils, being, of course, mechanically deposited by the air as it rushes in. Some of the children noticed little unless their attention was especially attracted, but the impression given was that they were directing attention rather to getting air, as deep labored breathing without interruption, hour after hour, calls for attention on the part of any conscious breather.

OUTCOME

In fatal cases death occurs in from 48 to 70 hours after the onset of labored breathing, 55 hours being about the average.

In the cases recovering, the duration of the stage of labored breathing is about the same. Death seems to occur from exhaustion. Convulsions have not been noted and coma has not developed till within a few hours of death.

The mortality in a series of thirty-two cases, occurring in my own practice or in consultation, has been 71 per cent.

POST-MORTEM APPEARANCE

Post-mortem examinations have been made in nine of the cases. The findings have been negative, as to the gross appearance of the organs, with the exception of the liver and the mucosa of the intestine; these were injected in some cases, in others not. The liver usually showed yellowish areas on the surface, extending downward to varying depths. The gall-bladder in all cases has been distended with dark, green, ropy bile. Microscopic examination of the organs has only shown fatty degeneration of the liver. Neither the heart, the kidney nor the muscles have been found fatty in any instance.

TREATMENT

Treatment has varied from eliminative to symptomatic, with the employment of strychnin in good doses, epinephrin and hypodermoclysis of normal salt solution. I am under the impression that treatment avails little when a sufficient injury has been done the system, but that hypodermoclysis is of decided value when the injury is not sufficient to be lethal.

CASE HISTORIES

Of the fourteen cases encountered during the last three years only three will be cited.

CASE 1.—Infant L., male, white, aged 10 months; breast fed; large and plump; never previously ill. The only food given other than breast milk was a few feedings of farinaceous food at irregular intervals. For four days prior to onset of symptoms the mother had noted that the bowels were loose, but as the baby did not seem sick she paid no attention to it. At 2 a. m. January 6, the mother found the baby breathing in a labored manner. The attending physician, Dr. Pressly,

did not reach the child till 9 a. m., seven hours later, when he found it very ill and restless, respirations 48 per minute, temperature 101. Hypodermoclysis was employed in the afternoon and I saw him in consultation at 9 p. m. The respirations were 40, pulse 120, rectal temperature 99.5. The liver was palpable below the border of the ribs. Thursday the child was reported to have progressed fairly well, probably as the result of the salt solution, but on the next morning, Friday, was called to see him again to find him in desperate straits. Respirations were 56, labored, and with an expiratory moan. Pulse not perceptible at wrist, rectal temperature 100, extremely restless. Liver enlarged to over an inch below border of ribs. The child was conscious, was taking water freely, and the kidneys had been acting well; the abdomen was not distended. The child died at 2 p. m., sixty hours after onset of symptoms. In this case vomiting occurred during the first twenty-four hours and did not recur. Post-mortem one hour and twenty-five minutes after death; rigor mortis fairly well developed; discoloration of posterior surfaces of the body; abundant adipose tissue under skin of abdomen. Liver extends two and a half inches below ensiform cartilage in median line and one inch below free border of ribs; yellowish areas over surface of liver, decidedly lighter in color than remainder of organ, gall-bladder distended with a dark green, ropy bile; stomach distended with gas; contains some mucus and the mucosa was congested in places; intestine empty except for the same dark green bile found in the gall-bladder; kidneys apparently normal; lungs normal and pink in color; heart normal; liver weighs 360 grams.

CASE 2.—Infant L., male, white, aged 2½ years. The child was breast-fed until weaned at the end of the first year. April 30 the child had two bloody actions, for which castor oil was prescribed by the attending physicians. Friday the mother reported the child so much better that he was not seen. On Saturday the attendant again called to find him with labored breathing, but only thirty to the minute. Vomiting began at midday. After twenty-four hours' vomiting of the water given, coffee grounds vomitus began. The patient was seen in consultation Sunday afternoon at six. Respirations 35, labored and deep; pulse feeble and irregular, 135; liver one and a half inches below free border of ribs; attendant states that he examined the liver the day previous and it was not enlarged; that he examined it again that morning, Sunday, and found it an inch below the ribs with the child vomiting every few minutes a coffee-grounds material, and calling piteously for cold water, which would be promptly rejected. The child was pale and washed out, very restless; mental state clear; kidneys active.

Seen again next morning at eight, its condition was much worse; respirations 44, pulse not countable at wrist; temperature 101.4; vomiting of coffee grounds material still continued. The child called for water but would not respond to questions or apparently take notice of things about him, and died later in the day, 55 hours after onset of symptoms. No post-mortem.

CASE 3.—Infant B., male, white, aged 15 months; breast raised and still nursing. Lately the child had been given buttermilk in addition. It was a well-nourished baby. Seen in consultation April 21, 1910, a history was obtained of slight colitis from the seventeenth, four days previously. The child was not sick enough to cause any concern till the day previously when he developed labored breathing and vomiting. There was obstipation from the onset of symptoms; respirations were 34, labored and deep; pulse 128, easily compressible; abdomen moderately distended with gas, liver an inch below free border of ribs and very tender to pressure; acetone odor of breath quite marked; breath cool to hand; temperature 99.5; mind clear. Hypodermoclysis of normal salt solution, strychnin and epinephrin were recommended. Next day the respirations were 44, temperature 100, pulse 140. Respirations were not so labored as on preceding day, but on least exertion child was badly winded; acetone odor less marked; liver extends two inches below free border of ribs.

On the next day, April 23, the respirations were 33 and not labored, temperature 100.4, pulse 140; liver retracted somewhat from day before, and edge less sharp to finger. On April

24 the child was better in every way: liver not palpable below border of ribs; barley gruel recommended.

A good report was received April 25, except that the barley water had disagreed, causing nausea and had been discontinued. April 26, in afternoon, there was a slight tendency to labored breathing noted on any exertion. Barley gruel and orange juice were given once, followed by vomiting, which kept up during the night and showed coffee-grounds material. When seen April 27, condition was desperate and had been so during the preceding night and that morning. The breathing could be heard as soon as one neared the room during the early morning hours. Respirations 40, pulse 160, child very restless; but vomiting had ceased; liver was felt one and a half inches below ensiform; tympany quite marked over abdomen.

On April 28 respirations 28 and not labored; pulse 150, temperature 100.2; tympany lessened. The child's condition was better and nourishment was again given, consisting of a half ounce of buttermilk. Medication consisted of strychnin and epinephrin. After the obstipation of the period of extreme illness, mucous stools reappeared and persisted during a tedious convalescence not complete to date.

This child received no nourishment from April 18 to 24, when barley water was given and disagreed. It was given barley water again on April 26, when vomiting was precipitated which came nearly being fatal. Buttermilk was given on the 28th and the child was nourished regularly thereafter. This recovery from a condition showing a mortality of over 71 per cent., and other recoveries from similar conditions under enforced starvation of from five to seven days, would seem to merit some attention, in view of the rôle assigned to starvation in the production of acidosis.

As to the nature of these cases, I have come to hold, tentatively, that they belong in the acidosis group; that a colitis, usually of mild type, through the production of some toxin, cripples the liver cells and, as a consequence of impaired liver function, products of faulty, incomplete metabolism are swept into the circulation and carried to the fixed tissue cells, which are dependent, of course, on the blood for proper nutritive and oxidative substances.

Dr. James Ewing¹ has presented elsewhere a thorough discussion, in which he freely admits the difficulties inherent in a question that involves the many unsettled problems of metabolism, and I think every one who has made any study of the question will fully agree with him. He divides cases of acidosis into two main groups: one without fatty degeneration, as represented by diabetic acidosis, and one with fatty degeneration, represented by the toxemia of pregnancy, delayed chloroform poisoning, Eek's fistula, cyclic vomiting in children and poisoning by hematoxic immune serum.

Only recently a professional neighbor was relating the history of a case of toxemia of pregnancy in a woman who had passed successfully through five pregnancies. With my own case in mind, he was asked if dysentery had preceded the onset of toxemic symptoms, and he replied in the affirmative. This question was further suggested by the history of a non-pregnant adult female, in whom a most serious acidosis was precipitated apparently by a mild dysentery.

If we are right in assigning our series of cases to the acidosis group represented by toxemia of pregnancy or by delayed chloroform poisoning, we have traveled only a short way on the road of explanation. We have not explained why the liver enlarges so rapidly; we have not explained the fatty degeneration of the liver, the changes

in the bile, the obstipation, nor the factors involved in the air hunger.

Hematoxic immune serum injected into an animal produces fatty degeneration or necrosis, according to the dosage. A ligated hepatic artery results in increase of fats in the liver cells, according to Holmes and Pearce, but the explanation of these results leads to as many theories, practically, as there are investigators. So long as physiologic chemistry fails to account for all the processes involved in the functions of the liver, so long as physiology fails to agree on the functions of the liver, so long as the rôle of the internal secretions is undetermined and the intimate processes of cell nutrition, including tissue respiration, are matters of conflicting theories, it is not to be expected that definite conclusions will be formulated, either by the laboratory worker or the clinician.

Considerable effort was made to discover the explanation of the air hunger met with in all of this series of cases.

Haldane and his coworkers have apparently demonstrated that hyperpnea, labored breathing, results from carbon dioxid tension in the respiratory center, and that the threshold at which the carbon dioxid excites the center may be lowered by acid or other products resulting from the want of oxygen.

No cyanosis exists in any of the cases, as would pertain if the blood contained excess of carbon dioxid, and there is no lack of oxygen in the alveolar air inspired, so that some other factor must be involved beside want of oxygen in the alveolar air.

An original worker writes in a personal letter:

There may be incomplete oxidation in the presence of abundant oxygen in the blood, because the factors—enzymatic or otherwise—which normally cause oxidation are defective. This would, of course, be defective metabolism. Just what the factors of oxidation are, is the dark problem. The intermediate acids combine with the bases of the respiratory center (Na_2CO_3 , NaHCO_3 , NaHPO_4 , etc.) and the free CO_2 resulting, remains in the center, causing increased tension and hyperpnea.

And thus we seem to be carried back to the original question involved in acidosis—the production of intermediate acids. Whatever the ultimate explanation of the air hunger, it appears reasonable to think that this explanation will mean the settlement of the controversy between those physiologists who hold respiration to be accounted for by the laws governing diffusion of gases and those who hold vital cell action to be involved.

ABSTRACT OF DISCUSSION

DR. JOHN ZAHORSKY, St. Louis: I have seen altogether five cases that fitted this syndrome exactly. All were fatal. I have studied this syndrome from a variety of standpoints, but a year ago I had a patient that put me on an entirely new track. This little boy, two and a half years old, had recurrent attacks of cyclic vomiting and in one of these attacks there seemed a little indigestion and the mother gave him a dose of calomel. This deep breathing developed and the liver swelled enormously, extending to the umbilicus. The pulse was not very full, the child was very sick and I was afraid it would die. That suggested how this syndrome might be explained, i. e., by acute dilatation of the right side of the heart. I could not explain how this liver could swell to twice its normal size except by edema or congestion, and passive congestion seemed to be the cause in this case, and that could most easily be explained by an acute dilatation of the right ventricle. We know that deep breathing is one of the symptoms of dilatation or weakness of the right heart. It is true

1. Ewing, James: Acidosis and Associated Conditions, Arch. Int. Med., 1908, ii, 330.

that there was no marked cyanosis or swelling of the veins of the upper extremity, but as there is diarrhea and vomiting with the loss of a large quantity of fluid, we can understand how there might be this accumulation of blood in the liver and yet not such an accumulation of blood in the upper extremities. One boy had spasmodic croup with severe suffocative attacks. I was asked to intubate the child and on examination no marked obstruction in the larynx was found, but he had this very deep breathing which was mistaken for obstruction. The liver was enormously enlarged, reaching almost to the umbilicus. Another child had cardiac disease. He suddenly had some severe symptoms and developed this deep breathing and also had this swollen liver. I have concluded that this deep breathing and enlarged liver are due to an acute cardiac dilatation which may be incidental to any acute disease, such as acute gastritis, acute gastro-duodenitis or colitis, or severe vomiting forcing the blood into the heart and stretching the right ventricle. So, while I originally considered Parke's syndrome a definite disease, I believe it is merely a group of symptoms occurring in many diseases. The acidosis is due to faulty metabolism in the absence of carbohydrates, and is not the cause of the disease.

Dr. ISAAC A. ABT, Chicago: I am already on record as having seen a number of these cases, I think a dozen or more. In nearly every one I have had an autopsy performed. In the first case, the child of a physician, the symptoms were pretty much as outlined by Dr. Parke. The child falls suddenly ill, vomiting, rapid respiration, rapid, small pulse, and goes gradually into a coma and last of all develops symptoms of obstruction of the bowel, due probably to extreme atony. They have all shown at autopsy, uniformly, fatty degeneration of all the organs. Dr. Ricketts, who did the autopsy work in the first case, thought that possibly the child might have eaten matches, so profound and extensive was the fatty degeneration. We found not only acetone but leucin and tyrosin in the urine. Dr. Ricketts found that the heart muscle and the intima of the vessel walls showed fatty changes. I think this is a syndrome that is a pathologic entity and depends on some grave toxemia. The acidosis is merely a symptom, and it is of no more importance than the rapid breathing, the rapid pulse, or the mechanical obstruction of the bowels, and it would be wrong to ascribe too much importance to it. I discussed these cases with a pioneer physician of Illinois and he suggested their close resemblance to the disease described as milk-sickness in cattle. Inquiring more closely into the subject one finds that milk-sickness or trembles bears a striking similarity in symptoms to those which Dr. Parke noticed in his patients.

Dr. THOMAS D. PARKE, Birmingham, Ala.: There was no coma in any of these cases and there was no mechanical obstruction. There was dysentery and poor digestion and though the bowels did not act during the period of labored breathing, after this stage of labored breathing passed off, the bowels became loose again. I am sure there was no mechanical obstruction in any single case. I am sure not only from the post-mortems that I made but from the patients that recovered. There is a good deal more in the acidosis problem yet to be cleared up and I think you will agree with me if you will study the paper by Dr. Ewing in the December, 1908, issue of the *Journal of Experimental Medicine*. My conception is that the injury done by the toxins of this intestinal trouble cripples the liver-cells and when you get crippling of the liver-cells, the products of intermediate metabolism are carried into the general circulation and produce the air hunger. Dr. Ewing attaches immense importance to this fatty degeneration. He says that these studies of the last few years show the immense importance of fatty degeneration. But we do not know just what work the liver has to do. I have been unable to find any physiologist who could tell me the complete function of the liver. I do not know whether the trouble is in the liver-cells or in the blood that is in the liver, and until we can get thoroughly worked out the full physiology of the liver we shall not know its pathology.

SYPHILITIC DISEASE OF THE ARTERIES OF THE CENTRAL NERVOUS SYSTEM WITH DETAILED REPORT OF A CASE*

E. M. HUMMEL, M.D.

Visiting Neurologist, Charity Hospital

NEW ORLEANS

The importance of arteritis or endarteritis as a lesion of syphilis has become well appreciated, especially since the writings of Huebner, Baumgarten, Marchand, Rieder, Nonne, and others. Only recently, however, has sufficient emphasis been placed on the tendency of specific arteritis to appear shortly after primary infection, and on the relative frequency of isolated involvement of the arterial system as compared to the other rather more familiar forms of nervous syphilis implicating the meninges and surrounding structures of the central organ, etc.

As regards the time elapsing between the occurrence of the initial sore and the intervention of symptoms of arterial disease, the tendency of recent writers on this subject, especially Nonne, of Hamburg, is to insist on the very early development of arteritis after the primary infection. The latter author quotes a case in which symptoms of cerebral softening occurred even before the primary sore had healed.

Not only is arteritis now looked on as an early process of syphilis, but it is even held that this lesion in its pure form practically does not occur in very late syphilis, and that nearly all cases occur within three years after the chancre.

Again it is necessary to recognize the frequency of arteritis as one of the grand diseases of the nervous system assignable to syphilis, because both treatment and prognosis are altogether determined by the nature of the processes in the nerve tissues associated with the arterial disease. Only by arriving at a proper conception of the lesions in such instances can the medical attendant properly interpret the phenomena occurring. It is rather probable that disappointment arising out of too sanguine expectations from the application of proper specific treatment, under the mistaken assumption that a gummatous or exudative process is being attacked, in instances of softening and hemorrhage in the central nervous organ, has been the occasion for physicians discarding the correct diagnosis of syphilitic disease, and consequently neglecting the effective agents of treatment subsequently.

It is unnecessary to dwell on the nature of the changes occurring in the arteries, because these are quite well understood. It is important only to recall that the process is practically always a proliferation of the intima with consequent encroachment on the lumen of the vessel and mechanical interference with the passage of the blood-current. And we do not have to wait for complete occlusion of the vessel in the expectation of symptoms, but a very important group of syphilitic nervous diseases is caused by mere diminution of the blood-supply to the tissues, giving symptoms of neurasthenia, transient pareses, and the like, not extending to the gravity of organic disease. In such instances the alterations in the arterial walls, especially in the smaller vessels, further interfere with the interchange of nutritive fluids, thus contributing to the so-called functional disturb-

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

ances. As a matter of course, it is very important to interpret such symptoms correctly and early, for proper treatment is then most hopeful.

When actual hemorrhage, softening, or thrombosis occurs, the pathology and symptoms are in no wise peculiar to luetic arteritis, unless we regard the tendency of syphilis to select the branches of the middle cerebral artery as especially great. In my experience with a number of cases, I have found that the involvement of the arteries to the striate body, thalamus and the bulb especially frequent. The interesting lesions seen in the photographs of specimens from the case I am presenting, emphasize this. In this instance the lenticulo-striate group of arteries were almost all completely obliterated, leading to practically complete death of these structures on the right side and pronounced softening on the other.

I deem it somewhat foreign to the purpose of the present paper to more than refer to the fact that syphilis is the remote cause of aneurismal processes very late after the infection, operating in conjunction with agencies tending to raise the blood-pressure, such as atheroma, cardiac and renal diseases. This latter observation, however, serves in this connection to emphasize again the great tendency of syphilis to inflict wide-spread damage on the arterial tree.

I shall finish these few generalizations with reference to a case in which I was fortunate enough to follow the symptoms over a period of twenty months, the case finally coming to necropsy. Although I was not able to get the necropsy done in the best manner possible, and to prepare the specimens completely, I have succeeded in securing photographs and slides of two transverse sections which display the most pronounced lesions in a fairly satisfactory manner.

History.—The patient was a white man, aged 36, single, bartender by occupation, and came under observation March 26, 1908. Aside from the fact that the father was alcoholic, the family history was negative. The patient was exceptionally well as a child and during adolescence. In fact, there was no illness of consequence until he acquired syphilis. Beginning at the age of about 25, he led a very dissolute life, drank alcohol steadily and went on occasional week-end drunks; used tobacco and drank coffee to excess. During September, 1906, he contracted a venereal sore and had well-marked secondaries. Treatment was instituted and kept up in a desultory way for two years after appearance of secondary symptoms. There was seemingly no further manifestation of syphilitic activity until November, 1907, when the patient sustained a stroke of partial hemiplegia of the left side. The hemiplegic stroke was, however, preceded by dizziness and malaise for several weeks; and on treatment the weakness on the left side improved greatly, but never got entirely well. A short time before my observation, he became dull and confused, laughed and cried without cause, and showed other signs of disturbed mentalization.

Examination.—On first physical examination (March 26, 1908), the following observations were made: All deep reflexes were exaggerated, but those of the left arm and leg were most pronouncedly so; ankle clonus partially developed on left, exhausting after a few seconds; the left epigastric and hypogastric reflexes were absent; Babinski sign present on the left, Gordon sign on the right; Romberg test positive. It was impossible to test sensation carefully on account of the mental state, though there was obviously diminution of pain sense on the left side of the body. There was marked weakness of the left arm and leg. With the hands, 38 kilos on right and 12 on left, could be registered on the dynamometer. There was no sign of facial weakness on either side. Tongue deviated slightly to the left; pupils equal, round, active to light and accommodation. There was very slight swelling of the optic disks with obscuration of the edges and what appeared to be

a mild toxic retinitis. The patient articulated awkwardly as if the tongue and lips were stiff on voluntary movement, and the voice was nasal. The soft palate sagged, but was observed to move on forced voluntary effort, not, however, on stimulation. The heart and other important viscera were normal; urine examination being likewise negative. The bowels were obstinately constipated and the tongue had a white coating. Control of the bladder was somewhat impaired, though this could not be determined well on account of the mental state. No hardening could be detected in the peripheral arteries. The mental state was one of universal reduction of all the psychic aptitudes. Patient was unable to tell where he was or anything about his situation. On attempting to answer questions, there was an overplay of the facial muscles of expression and articulation, and the effort would almost invariably end in a fit of crying. Words were enunciated in a clumsy way, amounting to dysarthria. The tendency to weeping obviously did not signify affective depression but the emotional instability seen in cases of gross lesions of the basal structures, especially the optic thalamus and striate bodies. The patient had no care for personal cleanliness. These and numerous other faults of behavior seemingly have their explanation in the mental state of bewilderment and negativism present. Specific treatment was given, but was so poorly tolerated that it had to be used very mildly. The digestive functions seemed to be in abeyance, constipation was obstinate and the general state grew worse.

Fig. 1.—Syphilitic endarteritis.

Subsequent Course of Disease.—May 4, 1908: General state somewhat worse than on last observation; patient required careful nursing, drooled saliva and refused food. Emotional instability continued; patient articulated badly; the gait was now somewhat more spastic; condition of the eye fundus remained the same; Babinski sign was present on both sides. Specific medication increased in quantity.

June 9, 1908: The general state was observed to be improved; patient would now articulate his words better, knew that he was in the hospital, took his food better and gained in weight; spasticity in extremities was much diminished; Babinski sign present on both sides; deep reflexes greatly plus, most pronounced on left.

June 16, 1908: Condition quite the same as on previous observation, possibly a bit better. Patient left the hospital.

During the month of October, 1908, patient was seen casually on the street and seemed almost normal. The gait was unimpaired and he asserted that he could use his extremities as well as ever. He felt strong and expressed intention of resuming his occupation. He was readmitted Aug. 15, 1909, having become practically helpless in all four extremities.

October 2, 1909, the following observations were made: Patient's condition was worse than when first seen. He cried almost continually; signs of the old left hemiplegia were again prominent, and the right side was also weak and spastic; the arms were stiff and awkward on voluntary movement; pronounced weakness in both arms and legs, but most pronounced in left; deep reflexes greatly exaggerated on the

left, less so on the right; sustained ankle-clonus on the left; Babinski sign present on both sides. Sensation could not be tested on account of mental state. No athetoid movements or tremors present. The mental state was the same in kind as that seen on first observation, though of greater depth. The patient lay quietly and discharged the functions of his body without concern, requiring to be fed like a child. Articulation was scarcely intelligible, and he had great difficulty in swallowing. Specific treatment was again instituted, but totally disagreed and had to be withdrawn.

Nov. 28, 1909: Patient was bedridden and could scarcely swallow food from involvement of deglutitory muscles. The mental state was one of negativism, due to the profound reduction of all cerebral functions. He still continued to cry when aroused. Babinski sign was present on both sides; sustained ankle-clonus on left. The optic disks remained partially obscured as noted on previous observations. The patient moved his extremities in an awkward, ataxic, spastic manner; was obstinately constipated and abutments were retracted. Patient was unable to swallow and seemed not to assimilate nourishment given by stomach-tube.

He died December, 1909, from inanition.

Clinical Diagnosis.—Syphilitic endarteritis of the central nervous system, with focus of hemorrhage or softening at first in the right internal capsule; later similar involvement of the left capsule. Probably multiple small foci about the hemi-

Fig. 2.—Syphilitic endarteritis.

spheres from rupture or obliteration of the smaller terminal vessels.

Post-Mortem Findings.—There were found slight universal thickening of the dura, and wide-spread opacities of the pia with cystic formations in places. The walls of the large vessels at the base were observed to be thickened, especially the middle cerebral and its branches. Areas of softening were seen in the region of the two striate bodies, most marked on the right, where the lesion appeared older and involved the thalamus and practically all structures in the lenticulo-striate region, apparently destroying the majority of the fibers of the capsule. These were the two chief gross lesions, but numerous minute foci of necrobiosis were seen in the cortex and subcortical substance of the hemispheres.

Transverse sections of the spinal cord showed the left half of this organ to be distinctly less in volume than the right. The pyramidal tracts were seen to be greatly atrophied on naked eye inspection, apparently from secondary degeneration alone.

On account of the difficulties under which our observations were made, no Wassermann reaction could be done and no search for spirochetes made; but the clinical history and appearances of the lesions found were so overwhelmingly in favor of syphilis as to leave no reasonable doubt.

I realize the great interest that might have attached to a more detailed observation of the symptoms in the case and the exhibition of microscopic sections of the

brain and cord in further illustration of the interesting pathologic lesions present. Lack of opportunity prevented my doing the former. I hope to complete the pathologic work later.

I have the pleasure to express my thanks to Drs. Daspit, Duval, and Couret, who have so kindly assisted me in securing and preparing the specimens.

1328 Second Street.

ABSTRACT OF DISCUSSION

DR. WILLIAM W. GRAVES, St. Louis: Dr. Hummel referred to the frequency of early arterial degenerations as a manifestation of syphilis, especially as pointed out by Nonne in recent years. This great clinical fact is one which is not appreciated. Early arterial degeneration after a syphilitic infection, no matter how carefully treated, is the one preeminent clinical fact on which one may oftentimes hinge a provisional diagnosis. Signs of arterial degeneration, occurring in a man before his time, and one being able to exclude metallic and other poisons as the cause, are in the majority of cases due to a former syphilitic infection. I base this conclusion not on that finding alone, but there are other clinical findings demonstrable in cases of syphilis two or more years after the infection, which are almost as constant as the arterial changes.

During the last few years I have given much attention to syphilis of the nervous system and post syphilitic conditions, and I have made careful studies not only of the arterial systems of syphilitics, but also of their nervous systems; and from these studies it may be stated, though I may be considered radical when I do state it, that there are but few patients, however carefully we may treat them, who two years after a syphilitic infection will not show organic changes as demonstrable by a clinical consideration of the nervous system. Indeed during the secondary manifestations of syphilis in some cases which I have had the opportunity of studying, I have found distinct sensory loss, especially to pin pricks. This loss may and probably does remain throughout the life of the individual. A syphilitic may lead a healthful life, but he reacts badly. The individual who has had a syphilitic infection must be regarded as a blighted individual, reacting poorly to stresses and strains. Such individuals when studied, in addition to cardiovascular changes, show in the majority of cases changes in the oculo-pupillary apparatus and in the nervous system.

DR. GEORGE A. MOLEEN, Denver: I have been greatly pleased with the case report that has just been made, and I believe that this condition is too often neglected by reason of its frequent occurrence. The first phase that appeals to me in this paper is the evidence of neglected syphilis which has been the cause of the arterial degeneration. I have seen quite a number of cases of cerebral arterial degeneration in Colorado, and almost invariably the history of the syphilitic infection carries with it an incompleting treatment, or a treatment extending usually not over two or three months. The length of time of specific treatment, I think, is often in direct relation to the occurrence of an arteritis. I have seen in one instance the occurrence of a syphilitic arteritis within three months of the initial sore. In other cases they have gone, as has been the experience of others, as long as fifteen or twenty or more years. The mental confusion in the case just cited, I take it, is an expression of the general toxic effect of the syphilitic virus, which is further evidenced by the neuritis and the retinitis, and these are not commonly, if ever, present in pure arterial lesions. I do not believe that many such cases should occur if the proper mercurial treatment were established and continued, and particularly continued when once established. I think with Osler that it is lamentable that we should find arterial lesions in specific cases like these, which are so amenable to mercurial treatment.

DR. THEODORE DILLER, Pittsburg: There is a good deal of thickening of arteries, a good deal of arteriosclerosis, that is not syphilitic. For instance, I very often find thickening of arteries in boys with dementia præcox, and I believe that there

is a good deal in the inheritance of bad arteries, arteries which degenerate early, and I feel that we ought to be not too hasty in concluding that thickened arteries indicate specific disease, even in young persons.

DR. E. M. HUMMEL, New Orleans: Fourteen months elapsed between the time of the initial sore and the stroke of hemiplegia which this man suffered, which in the light of subsequent developments was undoubtedly assignable to softening in the right capsule due to obliterating endarteritis. I wish to insist again on the early occurrence of signs of specific endarteritis, dating from the time of the initial sore. Dr. Nonne in his comprehensive treatise, "*Syphilis und Nerven-System*," insists on this repeatedly, and comes to the conclusion that syphilitic processes of this kind always occur practically within three years of the time of the infection. I did not wish to be understood as confusing specific endarteritis with arteritis of other causation, and I quite agree with Dr. Diller that there are numbers of other kinds of endarteritis, but I think, everything considered, there is no doubting the specific character of the arteritic process in this case. There is one point that I should like to mention further in connection with the case, and that is that it is noted in the clinical symptoms that this man underwent great improvement under specific treatment and got practically well. The explanation of that is interesting. It is probable that there was a large exudate around the site of the original softening, and that it was absorbed under specific treatment. One thing further in this connection and of interest here is that when a person under the age of 40 sustains a stroke of hemiplegia or any other sign of gross focal, brain or spinal cord trouble, coming on suddenly, indicating either hemorrhage or softening, the presumption is very strong that such an accident at so early an age indicates the presence of arterial disease of specific causation and the case ought not to be deprived of a therapeutic trial with antisyphilitic agents.

A NEW METHOD OF VACCINATION.

SIGMUND WASSERMANN, M.D.
CLEVELAND

All physicians will agree that with the vaccination method now in vogue, using the scarifier (*Impf-Lanzette*), we can never measure the extent of the trauma and therefore the resulting lesion. As a rule, with experience, we may strike just about the right thing, but in the case of a restless child an unexpected motion on our part or on the part of the patient makes us go beyond the intentional limits. A further point, which has not been considered sufficiently, is that such a large abraded area is a receptacle of a large quantity of vaccine lymph causing too strong a local reaction. Such and other drawbacks can be prevented by a new method, which I herewith present. This method revolves around the instrument ~~to be used~~, which is the scarifier devised by Professor von Pirquet for his cutaneous tuberculin test. It is a small chisel with the sharpened edge of which the drilling of the skin is surprisingly painless, hardly perceptible by children.

MODUS OPERANDI

1. Clean the arm with water and soap, and then rub it thoroughly with alcohol.
2. Apply the vaccine lymph (pulp) on the skin by expressing a capillary tube or by smearing the lymph, in case one prefers the points.
3. Point the chisel perpendicularly to the surface of the skin and press against it with a few rotary movements or, as a child said, "use it like a screw-driver."

These few rotary movements suffice to produce both an abrasion of the skin and an implantation of a minimum amount of vaccine virus.

Within a minute a little wheal, a typical, reddish urticarial papule with a central depression, is formed. It is a vasomotor reaction produced by the blunt pressure of the instrument.

I always cease the operation when the superficial layers of the epidermis appear to be removed and a pinkish hue shines through from beneath (vessels of the *pars papillaris corii*). I have never seen a trace of blood oozing from the scarified skin, which is by no means an attribute of a successful vaccination, as some believe.

DEVELOPMENT OF THE PUSTULE

The course of development is as follows: The traumatic papule spoken of fades away in a few hours and the incubation period begins. Nothing is seen or felt until about the end of the first week, when a little elevation is formed around the point of trauma. A very small area of redness may be seen at this time. This papule transforms itself into a vesicle within the second week, and becomes mature at the end of second or the beginning of the third week.

The most striking peculiarity of this form of vaccination is the mild and slow development, so that neither children nor parents are aware of the effects of the vaccination until the pustule is well formed. In the

Vaccine pustules (new method). Strictly circular, of geometric accuracy. Although very close, their individual halo can be distinguished, no confluence having taken place. Surrounding tissue is only slightly involved.

majority of cases, no subjective symptoms worthy of being mentioned are complained of during the first week (itching). During the second and third week, when the pustule is ripening and the area congested, there is seldom felt a pain in the axillary region. I have not yet witnessed an involvement of the whole arm, as the reactive congestion is small and keeps within the nearest boundaries of the pustule; neither does a bacterial infection take place readily. I have not had a single case showing these little accidents, as in previous years, although the vaccinations performed this year surpassed all those of previous years, on account of the smallpox scare in Cleveland. I explain this in the following way:

Scarifying, especially crosswise, means dissemination of little traumatic lesions over an unlimited area. After the inunction a crop of little pustules will sprout, and a confluence takes place to form a large unbounded pustular surface with an extensive area (halo). The crust later formed cannot completely cover the wound. It is not uniformly thick to resist the exuberant fluid; the scab cracks; matter overflows, sometimes resulting in an unnecessary secondary vaccination, and (what is of more

importance) making an open door for a bacterial invasion. "A scarification produced by rotary movements is more advantageous than scarification by incisions, as it gives a very small superficial wound."¹ These advantages of the drilling method, emphasized by Von Pirquet in his cutaneous tuberculin test, hold equally good of the ordinary vaccination. With this new method, only a single traumatic circumscribed lesion is formed. A minimum of vaccine material is used, and an almost geometrically circular pustule ripens sharply. A crust is formed and covers the underground completely and cover and contents dry down slowly without breaking—the main issue in any uneventful vaccination.

A MODIFICATION OF THE YOUNG PROSTATIC TRACTOR

HARVEY A. MOORE, M.D.

Clinical Professor Genito-Urinary Surgery, Indiana University School of Medicine; Attending Surgeon, Indianapolis City Hospital
INDIANAPOLIS

I have used Dr. Hugh H. Young's prostatic tractor successfully in a number of perineal prostatectomies, yet I have found it very difficult of introduction in a few cases and have therefore devised the instrument here illustrated, which is straight and has the advantage of being

Modification of the Young prostatic tractor; A, parts separated for cleansing and sterilizing; B, instrument closed for introduction; C, instrument open for traction.

easily introduced through the perineal opening in the urethra. By turning the thumb-screw the blades are opened at right angles to the shaft, giving the shape and the tractile advantages of the original instrument.

COBWEB BRAIN

A CONTRIBUTION TO THE PATHOLOGY OF IDIOCY

EDWARD LIVINGSTON HUNT, M.D.,

Instructor in Neurology, Columbia University; Visiting Neurologist to New York City Home for the Aged; Neurologist to the Penitentiary and Workhouse Hospitals; Senior Visiting Neurologist to the Hospital for Nervous Diseases of the City of New York
NEW YORK

The following case occurred in the service of Dr. Robert Abbe at St. Luke's Hospital, New York City. I was called to see the child in the capacity of acting neurologist.

The family were most insistent that something be done to investigate the condition of the child's brain, and therefore urged an exploratory operation.

Fig. 1.—Anterior view, showing the appearance of the frontal lobes; cerebellum is above and behind.

History.—Dorothy C., born Nov. 6, 1906, admitted to St. Luke's Hospital Feb. 27, 1910. The labor began on the morning of November 6; the premonitory symptoms were those of placenta previa. The delivery, hastened by high forceps, was completed the same afternoon. The child was rendered conscious only after considerable efforts. The examination made at the time of birth showed an extensive cut over the right eye, and on both right and left sides an immense swelling at the back of the top of the head. The one on the right side was the larger. During the first month the child was kept in an incubator and sustained by nutrient enemata, gavage, and oxygen. For several days after birth the child had periodical convulsions, as was shown by facial distortions and rigidity of the muscles of the face and arms. These convulsions, which were accompanied by cries, lasted three or four minutes and occurred several times in a day. They lasted several days and then gradually disappeared. The child was apathetic, unobedient, and apparently without emotion. The hands were constantly kept clenched. An external stimulus would elicit a cry; it was thought that sight was present. The child gave every appearance, however, of being an idiot.

Physical Examination.—Well-nourished child of 3. The symptoms on admission were as follows: The child did not talk—never had. If laid on her back she would kick vigorously. Sight was undoubtedly impaired, although there was a distinct realization of the change from extreme darkness to light; the sense of hearing was very acute; the sense of pleasure was apparent, as was shown when a familiar voice spoke; the sense of taste was present, as the child rejected certain things and enjoyed others. The legs showed equal development; the use of the right hand and arm seemed to be better developed than that of the left. The color was good. The child could not sit up; if held up the head fell to the side. The skull was asymmetrical, the diameter from the right cheek being greater than that from the left. There was no depression on the surface; the fontanelles were closed. A lighted match produced a spasm of the entire body and for a brief moment caused the eyes to follow it. Immediately after, however,

they began to roam and continued to do so aimlessly. Drooling was frequent. The jaw was constantly in motion as if chewing. Sixteen teeth were present; they projected very little from the gums. There was no glandular enlargement. The ears were normal. The heart, lungs, and abdomen were normal. There was no rigidity of the neck. The limbs were stiff and spastic, showing occasional aimless movements, without apparent coordination. The kneejerks were exaggerated. There was no Babinski and no Kernig sign. A pin-prick caused no pain. Temperature 101.3, pulse 120, respirations 22.

Ophthalmoscopic Examination.—This, made by Dr. C. W. Cutler, showed that both pupils were dilated; the left reacted to light, the right did not. The media was clear; there was a temporal atrophy of both nerves; an irregularity of the choroidal ring and a sharpness of the edges of the nerves.

Fig. 2.—Posterior view, showing normal size of cerebellum as compared with the very small shriveled appearance of the frontal lobes.

There was no exudate. There were some diffuse signs of an old chorioid retinitis. There was no nystagmus.

Operation.—On March 1, 1910, Dr. Abbe did an exploratory craniotomy. A curved incision 4 inches long was made in the right parietal region. The periosteum was elevated and the opening enlarged with rongeur forceps. The dura mater was bulging but on incision collapsed. The entire right hemisphere was replaced by a reticulum of cobweb-like tissue filled with clear watery fluid. No cerebral substance could be seen at operation, and the wound was closed. This cavity was evidently the result of an old clot, as many adhesive bands were left behind. The patient survived a few hours.

Autopsy.—Performed by Dr. Zinsner. There was a marked asymmetry of the skull, the right side bulging forward especially over the right parietal surface. The sagittal suture ran backward and to the left and there was a slight protuberance of about 1 cm. in extent over the right frontal region. The external appearance of the skull was otherwise normal. Under the incision made at the operation, that is, on the posterior half of the right parietal bone, a disk of skull had been removed. On the removal of the skull-cap a considerable escape of fluid took place where apparently the saw had penetrated the dura. The lateral hemispheres were considerably contracted, leaving a large space between brain and skull. The right hemisphere of the brain showed a very great and marked degree of shrinkage. It was practically a complete atrophy of the hemisphere. There was considerable dense connective tissue, which apparently drew the convolutions together. The cortical substance was extremely thin. The lateral ventricles were very much dilated. The left hemisphere had been converted into a large cystic mass, the cortex in some places being as thin as paper, transparent and distended with fluid. The remaining cortical substance was very thin, showing an attenuated layer of brain substance. The basal portions of the brain were well developed and apparently normal.

Acknowledgement is due the House Staff of St. Luke's Hospital, especially to Dr. Heaton, for the courtesy afforded me and for the assistance in collecting these facts.

UNUSUAL SITE OF TYPHOID PERFORATION

N. C. BLEDSOE, M.D.
BISBEE, ARIZONA

History.—July 8, 1910, J. H. M., a hoisting engineer, married, aged 37, came to see me, giving a history of trouble with his stomach. His temperature was 102.6 F., pulse 100. A diagnosis of typhoid fever was made and he was sent to the hospital, where he ran a very high temperature. He was put on a milk diet, given phenyl salicylate (2½ grs.) every three hours and sponged for temperature above 102.5. He was blue, so he was given whisky (½ oz.) after each sponging. Rose spots appeared on the fifth day in the hospital; on the seventh day he had a severe hemorrhage from the bowels. The patient was given morphin (¼ gr.), and all food withheld for forty-eight hours. He was given all the ice-cold normal salt solution that he would drink (he never made any complaint about it). In twelve hours his temperature dropped to 98, pulse 98, slower than it had been at any previous time. From that time until the tenth day he passed in all 73 ounces of blood. The abdomen was never distended, nor did the patient complain of any discomfort whatever. On the twelfth day at 3 a. m. he suddenly complained of severe pain in his stomach, radiating across the abdomen just under the costal arch. He was given codein (½ gr.) hypodermatically, and I went to the hospital as soon as I could. The codein quieted him a little. At 5 a. m. he had a chill and had very severe pain. Just previous to his attack of pain his condition was, temperature 101.6, pulse 104. When I examined him his pulse was 126, temperature 103 F., face drawn and anxious, both recti tense, but no distention. A diagnosis of perforation was made, relatives called, and all preparations made for operation. The family wanted consultation. A consultant was called and confirmed the diagnosis, but wanted to put off operating, as the patient was resting easily. One hour later his condition was decidedly worse; pulse 130, temperature 103, respiration 36. The relatives were told his condition. They decided, with the consent of the patient, not to operate.

The distention became very marked across the upper part of the abdomen above the transverse colon. The lower part of the abdomen remained flat, but more tense than ever. At 7 p. m. the patient died.

Perforation at the junction of pylorus and duodenum.

Autopsy.—This revealed typhoid ulcers over the whole of the intestinal tract; abdomen full of thin fecal matter; no perforation in the small intestine, or in the colon, but at the junction of the duodenum and the pylorus, as shown in the illustration, was the fatal perforation. On closer examination the perforation was found to be in the center of radiating bands of adhesions, looking like an old duodenal ulcer; it had healed and the typhoid infection had attacked this portion of the intestinal tract causing the perforation and death.

I can find no record in my medical literature of a perforation in this region, hence this report. We see so few perforations that it is hard to say definitely from

rise to no subjective symptoms. The overlying epidermis was normal in color. Two centimeters farther back was a second lesion, smaller than the first, and of a purplish hue. It was quite soft to the touch. Immediately below the anterior fold of the elbow-joint was a larger tumor (Fig. 2) (1.5 by 2 cm. in diameter, and 1 cm. in height), which was also purplish in color, and soft and compressible. Higher up, on the inner surface of the upper arm, were four more nodules, arranged in an irregular chain. In only one of these could fluctuation be obtained. The epitrochlear and axillary glands were not palpable. The signs which commonly mark the presence of an ascending cellulitis were absolutely lacking. The patient's temperature was normal, and she stated that if she had not seen the nodules on the wrist she would not know they were present. Permission to excise one of the smaller lesions was firmly refused.

Bacteriologic Examination.—A clinical diagnosis of sporotrichosis was made, and the case referred to Dr. W. K. Trimble, of this city, for bacteriologic examination. The large lesion near the elbow-joint was incised, under the usual precautions, and two agar and four glycerin-agar tubes inoculated. The pus was of a mahogany color, thick, stringy, and of the consistency of syrup. The tubes were placed in an incubator at 37 C. Four days later, there were abundant growths on all six. On investigation, it was found that pure cultures of the organism had developed on five of the slants (Fig. 3) (one glycerin-agar tube having become contaminated). Some of the patient's blood was secured, and an effort made to prove the feasibility of the spore-agglutination test. The method was found, however, to be of more theoretical than practical value.

Treatment.—Potassium iodid, in doses of from 2.0 to 3.0 gm. per day, has been found to be almost a specific in this disease (I am unable to discover who first suggested its use). Locally, a saturated aqueous solution of the same salt, or one of the iodine, potassium iodid, and oil mixtures, is of great value. The patient was placed on this line of treatment with extremely satisfactory results. When I last saw her, ten days after the first consultation, the lesions had almost entirely disappeared.

610 Commerce Building.

A CONTRIBUTION TO THE SUBJECT OF TUMORS OF THE HYPOPHYSIS

DEAN D. LEWIS, M.D.
CHICAGO

I. TUMORS DEVELOPING FROM CRANIO-PHARYNGEAL DUCT INCLUSIONS

In 1902 Saxer described an epithelial tumor which replaced the infundibulum of the hypophysis, filled up and distended the recessus infundibuli and the recessus opticus, and extended into the third ventricle so as to form a part of its floor, also into the lateral ventricle through the foramen of Monro. The anterior lobe of the hypophysis was normal and the tumor was unconnected with the choroid plexus. The nodular, free surface of the tumor, especially that projecting into the third ventricle, had a definite papillary structure. The papillae consisted of a fairly thick connective tissue ground work, which was covered by epithelial masses, the general arrangement of which corresponded to that of stratified flat epithelium. The most superficial epithelial layers consisted of flattened cells which were fusiform on cross section. The deeper layers were cubical or cylindrical and the cytoplasm of cells was markedly vacuolated. The vacuolation was one of the most striking features of the histologic picture.

In discussing the origin of this tumor Saxer states that he believed at first that the position of the tumor,

especially its relation to the floor of the third ventricle, which formed a considerable part of the upper surface of the growth, warranted him in concluding that it developed from the epithelium of the ventricle or its recess. He later changed his opinion regarding the origin of the growth, because of the character and arrangement of the connective tissue and the appearance of the epithelium, which resembled closely stratified, flat epithelium. He came to the conclusion that the cells of which this tumor was composed resembled morphologically the cells surrounding the infundibulum, which form what is now known as the *pars intermedia*. The relation of the *pars intermedia* to tumor formation will be discussed later.

Saxer in closing the discussion of this tumor states that he did not know of a record of a hypophyseal tumor with similar histologic characteristics. Scattered throughout the literature are descriptions of solid and cystic tumors occurring in the position occupied by the one described by Saxer. These have so many common gross and microscopic characteristics that they should undoubtedly be classified together. They appear in the literature under a number of different terms, such as epithelial tumor of the infundibulum and third ventricle, papilloma of the choroid plexus of the third ven-

Fig. 1. Photomicrograph of section prepared from tissue removed from Case 1. The tissue has a papillomatous structure. Cylindrical cells rest on the connective tissue stalk of the papillae, while the succeeding layers of cells vary in form, the difference apparently being due to pressure. Histologically this growth corresponds to a group of tumors which occur about the infundibulum and develop from cranio-pharyngeal duct inclusions.

tricle, cystic endothelioma developing from the pia mater, epithelioma of the Malpighian type, adenoma and adeno-sarcoma of the hypophysis. Before discussing the origin of these tumors, I wish to cite the histologic descriptions of some of the reported cases in order that I may compare the histology of these with that of the growth which I have examined.

Wagner in 1861 described a growth situated behind the optic chiasm, which displaced the optic tracts to either side. The tumor was composed of many small cysts separated by thin septa. When the posterior part of the growth was incised a cavity leading into a dilated third ventricle was exposed. The lateral and fourth ventricles were normal; the anterior lobe of the hypophysis intact. The cyst walls were composed of a

connective tissue. On the outer surface were numerous villus-like bodies which were covered with many layers of epithelium. The cells covering most of the villus-like bodies were cylindrical. In some areas they resembled stratified squamous epithelium while in others they were irregular in form and grouped in masses. Wagner expressed no opinion concerning the nature of this cyst which contained free cells and cholesterol crystals.

Langer¹ in 1892 reported two cystic growths which surrounded the infundibulum and extended up to the floor of the third ventricle. The walls of these cysts were composed of delicate, cellular connective tissue and supported papillary excrescences, which were covered by cylindrical epithelium. Langer came to the conclusion, after gross and microscopic examination, that these cystic growths took their origin in the infundibulum and that they developed from pieces of tissue constricted off from the anterior extremity of the central canal.

Harbitz describes a tumor which evidently belongs to the same group. It occurred in a woman 58 years of age, who presented none of the symptoms of acromegaly, but other symptoms associated with hypophyseal growths. The tumor occupied the position of the hypophysis. It was as large as a walnut and extended along the infundibulum upward to the floor of the third ventricle, with which it became continuous. The chiasm was stretched over the tumor, the right optic nerve was flat and ribbonlike and the right optic tract could not be distinctly seen. The left optic tract and nerve were normal. Microscopically the tumor presented a fairly uniform structure. The cells were grouped into masses of various shapes and sizes separated by a connective tissue stroma. The cells resting on the stroma were cylindrical with clear cytoplasm, while those occupying the center of the masses were polygonal, round or oval. In many fields the histologic picture resembled that of a papilloma. Harbitz believed that the tumor was an adenoma, although there were evidences of proliferating growths along the periphery.

The histologic characteristics of the tumors mentioned above have been cited at some length in order that they may be compared with those of a growth which, through the kindness of Drs. A. E. Halstead and E. R. LeCount, I have recently had the opportunity of examining. The growth was removed by Dr. Halstead at St. Luke's Hospital, Chicago, from a patient presenting the symptoms associated with hypophyseal growths but without acromegaly.

CASE 1.—The patient, a man aged 39, gave a history extending over a period of two years. He complained first of a frontal headache of a peculiar pricking or sticking character. A year later his eyesight began to fail. A perforated nasal septum and aortic regurgitation suggested the possibility of cerebral syphilis and vigorous antisyphilitic treatment was therefore instituted. It was continued for a number of months without improvement. There were no symptoms of acromegaly. The patient had been impotent for eighteen months. The external genitalia were, however, well developed; there was no adiposity or suggestion of the feminine type.

The diagnosis of an hypophyseal tumor was not made until bitemporal hemianopsia was added to narrowing of the visual fields and bilateral optic atrophy developed.

The diagnosis was verified by an x-ray picture which revealed a shadow occupying the sella turcica and apparently extending upward toward the floor of the third ventricle. The detailed history and postoperative course of this case have been reported by Dr. Halstead.²

Microscopic Examination.—Several fragments of tissue removed during the operation were submitted to me for examination. The tissue was fixed in Zenker's fluid and imbedded in paraffin. The sections were stained with hematoxylin and eosin, Van Gieson's picro-fuchsin, iron-hematoxylin and neutral gentian. The last two stains were used to determine whether or not intercellular bridges and specific granules were present.

Microscopically the growth presents a fairly uniform structure. It is quite cellular, the cells being grouped in masses of various shapes and sizes, which are separated by a delicate connective tissue stroma. In some regions the epithelium has a definite arrangement, a number of layers of cells resting on connective tissue forming the stalk of a papilla. The cells resting on the connective tissue are cylindrical; the cells of the superimposed layers are polygonal or fusiform, being considerably modified by pressure. The cylindrical cells stain differently. In some fields the part of the cell adjacent to the stroma is clear and vacuolated, the distal part staining heavily with eosin; the polygonal and fusiform cells, as a rule, have a clear cytoplasm which is vacuolated.

One of the most conspicuous features of the tumor is its papillomatous structure, but this is not found in all regions. In some the cells covering the connective tissue stalk are not separated from each other, the epithelial masses appearing to be fused. Histologically it appears as if the epithelial masses have been sunken into the connective tissue stroma, the picture often resembling that of a carcinoma, although there are no other cellular changes characteristic of malignancy. Secondary papillae have developed from the primary. In some areas these seem to be connected with the parent

Fig. 2.—Section of tissue removed from Case 2. The cell columns have fused. The cells found in this tissue are almost entirely of the eosinophil type. Hyperplasia is indicated by the large, irregular, fused cell columns, the preponderances of eosinophil cells and karyokinesis, which can be seen with the oil immersion lens (Zellw. Compens. Oc. 6, obj. 8 mm.).

papilla by a narrow pedicle; in others they lie free. The tissue, because of the peculiar arrangement of the secondary outgrowths, presents in many fields an alveolar structure. In some regions the lumen appears to be the result of the degeneration and subsequent liquefaction of cells, in other places masses of what appear to be colloid are present in the lumen of these cellular outgrowths.

I have been unable to demonstrate cells in these sections which resemble those of the anterior lobe of the hypophysis. Delicate granules can be demonstrated in some of the cells by the neutral gentian stain, but they do not have the characteristics of the chromophil cells of the anterior lobe. They correspond to nodal points in the spongiosoplasm of the cell. There is no evidence of keratohyalin or of psammoma granules. The endothelial cells of the blood-vessels, which are abundant, are not proliferating and the cells composing the tumor do not have the radiating, mantle-like arrangement of a perithelioma, so I believe that the tumor cannot be regarded as of either endothelial or perithelial origin. It presents none of the characteristics of a glioma or ependymal tumor. Nothing definite

1. Langer, F.: Ueber cystische Tumoren in Bezirken des Infundibulum Cerebri. Ztschr. f. Heilk., 1892, xiii, 57.
2. Surg., Gynec. and Obst., May, 1910.

can be said concerning the topographical relations of this growth as the field of operation is so deep and restricted in such cases. I believe, however, that it may justly be assumed from the x-ray findings that the tumor lay beneath the floor of the third ventricle and extended downward into the sella—a position occupied by the group of tumors under consideration.

There have appeared in the literature reports of several tumors in this position which have presented clinical as well as histologic similarities. None of these has contained elements peculiar to the anterior lobe of the hypophysis and as a consequence there has arisen con-

Fig. 3.—Pars intermedia of the ox.

siderable confusion as to their classification and origin. Because these growths are not associated with acromegaly, considerable doubt has arisen concerning the causal relationship between tumors of the hypophysis and this disease.

As previously mentioned, Saxer believed that the tumor observed by him took origin from a group of cells which are normally found about the infundibulum. These cells are regarded by a number of investigators as chief cells of the anterior lobe, which have invaded the infundibulum. This is apparently the view of Löwenstein. He states that his observations support the view of a number of other investigators who have found that in almost every adult the cells of the anterior lobe have invaded the posterior lobe. These cells in man lie in small groups surrounded by well developed connective tissue. They may be collected in solid cords or arranged in the form of a vesicle containing material resembling colloid. Those occurring in solid cords differ morphologically from the chief cells found in the anterior lobe, as the cytoplasm is more dense and stains more deeply. As far as I can determine, these cells are not so often vacuolated as those of the anterior lobe. The vesicles containing a colloid material are lined by a low cubical epithelium, the cells of which usually have a clearer cytoplasm than the other cells occurring in this region.

These cells are not to be regarded as invasions from the anterior lobe, but as distinct cellular elements of the

hypophysis, forming what has been called by Herring the pars intermedia. In man the development of this portion of the gland has apparently been somewhat suppressed. In the pig and ox, however, the pars intermedia has attained a much greater development, forming a large group of cells, which lie posterior to the hypophyseal cleft, the remains of the cavity of the hypophyseal vesicle. The cells of the pars intermedia in both the ox and the pig have a clear non-stainable cytoplasm and are grouped in cell columns with and without a lumen, the columns resting on the walls of numerous capillaries. The cells of the human hypophysis—which are regarded by many as ingrowths of the anterior lobe—undoubtedly correspond to those of the well developed pars intermedia of the pig and ox. Morphologically these cells are distinct, differentiation being well established, in a pig measuring 5 cm. Tumors with distinct morphological characteristics arise from the pars intermedia. The cases which have been observed will be mentioned later.

The tumor removed by Dr. Halstead does not contain any of the cellular elements peculiar to the anterior lobe and the pars intermedia. It corresponds in many respects to the descriptions of tumors given by Saxer, Harbitz, Babinski and Onanoff and others, which have been observed about the infundibulum. Some of these have been solid growths, the majority have been cystic. I believe that Saxer was wrong in thinking that the tumor described by him developed from the cells of the pars intermedia. His statements that the epithelium occurring in the tumor observed by him resembled stratified, flat epithelium is sufficient to exclude origin from these cells.

Fig. 4.—Cells of the pars intermedia of the human hypophysis showing their distribution in nervous tissue.

Erdheim⁴ was the first to recognize that a number of growths which had been found about the infundibulum, and had appeared in the literature under a number of different terms, belonged to one group. In 1904 he published a monograph dealing with seven cases which he had studied personally and with twelve cases collected from the literature which had appeared under a number

⁴ Erdheim, J.: Ueber Hypophysengang-Geschwülste und Hirn-Cholesteatome, Wien, 1904.

of different terms. Among the twelve tumors found in the literature, four were solid and eight cystic. Erdheim in examining his cases found cells with distinct intercellular bridges and epithelium which resembled closely stratified epithelium. In order to determine the frequency with which islands of undifferentiated cranio-pharyngeal epithelium occur in the hypophysis, he made serial sections of twenty glands. As islands of cranio-pharyngeal epithelium cannot be accurately determined in the fetus and newborn, because of the failure of complete differentiation, but thirteen glands were used in his studies. In ten of the thirteen cases he found islands of undifferentiated cranio-pharyngeal epithelium within the gland. The epithelial islands were situated in the infundibulum and the upper surface of the anterior lobe adjacent to it; also on the anterior surface of the posterior lobe. This peculiar distribution of this type of epithelium is due to the position of the cranio-pharyngeal duct in the final development of the gland.

While I have been unable to demonstrate intercellular bridges in the tumor under discussion I believe that it has enough of the characteristics common to this group to warrant one in placing it here. The epithelium of the cranio-pharyngeal duct is capable of forming adult cellular elements which differ markedly morphologically. The growth just described corresponds more closely to those arising from cranio-pharyngeal epithelium than to any other.

Some twenty-nine tumors have been described which belong to this group. The sex has been mentioned in twenty-eight, the tumor occurring nineteen times in the female and nine times in the male. The average age at which the tumor has developed is 32. The youngest patient was 9 years of age, the oldest 63.

The clinical courses of these cases have had fairly wide limits. Some cases have run a course of six or eight years, while others have been extremely acute. The patient observed by Bregmann and Steinhaus⁵ had been perfectly well four weeks before entering the hospital. Her illness began with severe pain about the left eye and convulsive movements of the left eyelid. Three weeks later she became apathetic, desired nothing to eat, gave no reply when talked to and showed no concern about her condition. General weakness was a marked feature of the clinical picture. She could not sit upright in bed without considerable difficulty and could not stand without assistance. The gait was ataxic, the left pupil dilated and immobile. Ptosis of the left lid, limitations of movements of the left eye upward and inward, spasm of the left orbicularis oculi, paresis of the lower branches of the right facial, paresis of the right side, especially of the lower extremity, ataxia of the right upper extremity, nasal twang to the voice and some difficulty in swallowing completed the clinical picture. The ophthalmoscopic examination was negative. The clinical diagnosis rested between brain tumor and encephalitis about the crura. The rapid clinical course and absence of pressure symptoms favored the diagnosis of encephalitis.

In Bartels' case the usual symptoms of brain tumor—dizziness, headache, vomiting and mental dullness—were absent and the pulse was constantly rapid. In this case the boy developed normally until 14 years of age, when the changes associated with dystrophia adiposo-genitalis developed rapidly—the clinical course of the tumor extending over a period of seven years.

No definite symptom-complex accompanies the development of these growths. Most of them have been associated with the usual symptoms of brain tumor, but these may be wanting or not pronounced as in the two

cases cited above. The most striking clinical feature, also perhaps the most constant, is the early loss of eyesight, optic atrophy developing in most of the cases without preceding choking of the disk. Choked disk is apparently much less common with hypophyseal than other intracranial growths. Bartels⁶ has collected forty cases of tumors of the hypophysis and studied their relation to choked disk. In twenty of these, 50 per cent., there was simple bilateral atrophy, one unilateral atrophy, in 15 per cent., double choked disk, in 15 per cent. neuritis with subsequent atrophy and in 10 per cent. there was no change at all. These statistics do not support Berger's statement that a very considerable percentage of the tumors of the hypophysis are accompanied by choked disk instead of optic atrophy.

In the clinical histories of nine of the recorded cases of tumor involving the infundibulum—only cases are included which apparently developed from cranio-pharyngeal inclusions—it is noted that the patient was fleshy or had some evidence of interference with genital development, such as small external genitalia or the absence of or falling out of pubic and axillary hair. About 32 per cent. of the cases, then, have had some or all of the features associated with dystrophia adiposo-genitalis.

It has been recognized for a long time that deposition of fat and the development of the feminine type were frequently associated with hypophyseal tumors.

The cause of these trophic disturbances has been variously interpreted. Erdheim believes that the adiposity with genital atrophy, and in the male, with the development of the feminine type, the syndrome described by Fröhlich, is not due to any interference with the function of the hypophysis, but that it is the result of pressure exerted on certain centers at the base of the brain by the enlarging tumor. He has noticed that this syndrome has been most frequently associated with those tumors which grow out of the sella and extend to the base of the brain, and with those in which the tumor has not developed in the sella or the hypophysis proper, but from the infundibulum. In support of his view he cites a number of cases, such as those of Selke, Boyce and Beadles,⁷ Babinski, Cestan and Halberstadt and Gläser. The view advanced by Erdheim is supported by Bartels. It is an interesting fact that in all of these cases the tumor was so situated that it could easily interfere with the function and viability of the cells of the pars intermedia, even if the anterior lobe of the hypophysis were intact.

Fat may be taken on rapidly with brain tumors not occupying the sella or occurring about the infundibulum. The rapid deposition of fat is explained in these cases by the sedentary habits which the patients are obliged to lead as the result of loss of vision or to the apathy attendant on increased intracranial pressure. There is, however, no group of intracranial tumors so frequently associated with the Fröhlich syndrome as those occurring about the infundibulum, which during growth must interfere with the function of the cells of the pars intermedia. As previously mentioned, these cells are entirely distinct from those of the anterior lobe, and while one cannot assume that differences in morphology indicate differences in function, one cannot help being struck with the frequency with which these in-

fundibular tumors—composed of a type of epithelium foreign to the hypophysis—are associated with Fröhlich's syndrome.

The association is so common that one is justified in making a diagnosis of an infundibular growth—probably of cranio-pharyngeal origin—when this syndrome, accompanied by eye changes, develops without any symptoms of acromegaly.

Cushing's⁸ experimental work would seem to indicate that hypopituitarism is the cause of dystrophia adiposogenitalis. This syndrome may be associated in acromegaly. It is difficult to explain this combination of symptoms, if acromegaly is dependent on hyperactivity of the gland, unless we assume that the growth associated with the acromegalic symptoms has interfered with the activity of another part of the gland with a different function.

Creutzfeldt's table, published in 1908, shows that tumors developing from inclusions of the cranio-pharyngeal duct are the most common of the growths of the hypophysis unassociated with acromegaly. The following table indicates the frequency of different varieties of tumors in 55 cases of tumor of the hypophysis without acromegaly which came to autopsy:

No. Cases.	Character.	Per Cent.
19	Cranio-pharyngeal duct tumors.....	34.54
15	Sarcomas	27.27
5	Hyperplasia	9.09
3	Strumas	5.45
10	Adenomas	18.18
1	Metastatic growth from thyroid tumor.....	1.818
1	Teratoma	1.818
1	Lipoma	1.818

II. TUMORS DEVELOPING FROM THE PARS INTERMEDIA

Three cases are found in the literature in which the tumor originated in the cells of the pars intermedia.

Boyce and Beadles describe a small tumor at the base of the brain, which rested on the pituitary body but was entirely outside of the sella turcica. The tumor, which was round, firm, and as large as a medium-sized pea, appeared to be an accessory pituitary body. The gland was of about normal size and appearance and was quite independent of the tumor, except for a slender connection passing up to the infundibulum, from which the accessory body appeared to take origin. Microscopic examination showed that the infundibulum enlarged just above the hypophysis to form a small tumor which measured $\frac{1}{4}$ inch in diameter and projected posteriorly. The tumor was composed of large polygonal cells, larger than those met with in the anterior lobe. A few cells were polynuclear. In some instances the nuclear staining was poor. A definite, acinar grouping of the cells was only slightly apparent at the periphery, but numerous capillaries tended to produce a certain amount of lobulation. One must conclude from the description of the growth and the accompanying figure that it developed from the pars intermedia.

Erdheim mentions a growth which apparently originated in the pars intermedia. It occurred in the infundibulum of a woman 86 years of age and was about as large as a hemp seed. Microscopically it consisted of large cells with heavily-staining cytoplasm, which had grown into the fibrous tissue of the infundibulum, as the normal cells of the anterior lobe so frequently do, as Erdheim states.

Cushing in a recent article states that Crowe, while studying sections of a large adenomatous tumor at the base of the brain, removed from an excessively obese individual, who had died of pressure effects, found a normal, though compressed, anterior hypophyseal lobe with undoubted evidence that the growth originated from the pars intermedia alone. The vesicles contained colloid and the tumor resembled in its arrangement one which might have originated from the thyroid gland.

These are the only undoubted examples of tumors arising in the pars intermedia. I believe it quite possible, however, that some of the peculiar types of sarcoma and adenoma may have arisen from this portion of the gland, for mistakes in anatomic diagnosis could easily be made if the structure of this part of the gland were not recognized.

The tumors described by Boyce and Beadles and Erdheim occurred in women aged 74 and 86 respectively. Neither tumor had given rise to symptoms, being discovered accidentally during routine post-mortem examinations. The age and sex of the case observed by Cushing are not given. It is to be noted, however, that in this instance the patient was excessively obese.

III. HYPERPLASIA OF THE ANTERIOR LOBE OF THE HYPOPHYSIS WITH ACROMEGALY

CASE 2.—The patient was an unmarried woman aged 32. Her illness began two years ago with eye symptoms. Various diagnoses of these were made, until bitemporal hemianopsia, optic atrophy, severe headaches and vomiting, indicating enlargement of the hypophysis, developed. Unmistakable signs of acromegaly now manifested themselves. The diagnosis of a tumor of the hypophysis was verified by the x-ray findings. Menstruation had been irregular for over twelve years, but the flow was not diminished in amount. There had been no polyuria. No adiposity or change in the external genital characteristics had been noted. The technic employed in exposing the hypophysis has already been described by Dr. Halstead. After the fat surrounding the hypophysis had been removed a cyst-like mass with gelatinous contents, not unlike soft granulation tissue, was curetted away. The patient did not recover from the partial hypophysectomy. After the operation she presented a peculiar train of symptoms, which Dr. Hamburger has suggested may have been due to the rapid absorption of hypophyseal secretion. These symptoms had some features in common with those which so often follow partial thyroidectomies for the relief of Basedow's disease.

Microscopic Examination.—The tissues were fixed in Zenker's fluid, imbedded in paraffin and stained with neutral gentian, hematoxylin and eosin, copper-chrome-hematoxylin and Van Gieson's picro-fuchsin. In studying sections of the hypophysis in cases of acromegaly it is necessary to use fixing fluids which will preserve the granules, and stains which will differentiate them. Zenker's fluid gives very satisfactory results, as the chrome salt gives the best results with neutral gentian technic.

Iron-hematoxylin, copper-chrome-hematoxylin and Bensley's mitochondria stain—give good results after fixation in Zenker's fluid. The importance of fixing the granules and of using stains which differentiate them cannot be insisted on too strongly. Hypophyseal cells when proliferating tend to reproduce the structure of a sarcoma and mistakes in anatomic diagnosis have often been made because of the failure to use fixatives and stains which preserve and differentiate the granules. Benda⁹ was the first to call attention to the possibility of interpreting a hyperplasia or an adenoma of the hypophysis as a sarcoma. Mendel then reexamined some cases which had been regarded by him as sarcomas and when granule stains were employed he could demonstrate the granules peculiar to the cells of the anterior lobe of the hypophysis, thus confirming Benda's view.

The histologic appearance of the tissue from this case differs in the various fields. In some, the cell columns are cut parallel to their long axes and appear as long strands between a rather heavy fibrous tissue. The cells appear to be normal and their arrangement does not differ from that usually found in the gland. In other fields the connective tissue between the cell columns is markedly reduced in amount, the cell masses being larger than is normally the case and separated from each other by delicate strands of connective tissue. The histologic picture indicating fusion of adjacent cell columns. In these areas karyokinetic figures are quite frequently encountered in

8. Cushing, H.: The Functions of the Pituitary Body; Am. Jour. Med. Sc., 1910, cxxxix, 473.

9. Benda: Deutsch. med. Wchnschr., 1901, xxiii, 536.

the cells, karyokinesis being most active in the cells with a light brown cytoplasm with few granules, as they appear in copper chrome preparation.

The fusion in some fields becomes so marked that large cell masses without definite boundaries are formed. The histologic picture is that of hyperplasia ending in adenoma formation. I have attempted to determine whether the chromophobe or chromophile cells predominate. So many transitional phases are present that it is impossible to determine accurately the relative proportions of the different cells. Eosinophil cells predominate in the field represented in Figure 2. It is difficult to estimate the relative proportion of the different cellular elements in all of the fields. None of the large vesicular type of cell, largely free from granules, which Cushing is inclined to believe represents the active or at least discharged phase of the gland, is present.

Notwithstanding the number of articles which have appeared dealing with the relation existing between tumors of the hypophysis and acromegaly, there is still considerable diversity of opinion regarding it. Cagnetto¹⁰ believes that acromegaly is not the result of hypophyseal changes, but that the latter are the result of some obscure general disease. In support of this view he cites the following observations: 1. Cases of acromegaly have been observed without a tumor of the hypophysis. 2. Adenomas composed entirely of chromophobe elements but associated with acromegaly have been found. 3. Adenomas composed entirely of chromophil elements (regarded by many as the actively secreting cells of the glands), without acromegaly have been observed.

Those cases in which no changes have been found in acromegaly are open to doubt, for in some instances a careful histologic examination has not been made, and besides the possibility of a *Rachendach* or pharyngeal hypophysis has been overlooked. Haberfeld's¹¹ observations in this connection are exceedingly important. He has found almost constantly in patients of advanced age hypophyseal tissue in the vault of the pharynx, which is not to be regarded as embryonal rests which have undergone partial regressive changes, but as active hypophyseal tissue which is able to perform a function similar to the gland occupying the sella. Those cases in which no changes in the hypophysis have been described cannot be used as an argument against the hypophyseal origin of the disease, for even in the cases in which a careful histologic examination has revealed no changes a search for and examination of the pharyngeal hypophysis have not been made.

Our knowledge concerning the functional stages of the different cellular elements of the hypophysis is still imperfect. I believe that the histologic evidence favors the theory that the different cells of the anterior lobe are functional stages of each other and that the eosinophil elements represent the most actively functioning type. It is difficult to determine this, however, as it is practically impossible to exhaust the gland by repeated pilocarpin injections—a method which has yielded such good results in the study of the functional stages of glands with an external secretion. I attempted some five years ago to exhaust the cells of the anterior lobe by repeated pilocarpin injections without success.

Cagnetto and Modena have reported cases of acromegaly in which adenomas of the hypophysis were

found, which were composed entirely of chromophobe elements, which are regarded by many as the least actively functioning cells of the gland. It is difficult to determine what effect such a growth may have on the remaining cells of such a gland as the hypophysis. The similarity between hypophyseal and thyroid changes have been emphasized for some time. Hyperthyroidism may be associated with cystadenomas and even chondromas, and although actively functioning cells are not found in the tumors the symptoms subside when the growth is removed. The same relation may exist between an adenoma of the hypophysis composed entirely of chromophobe elements and acromegaly as may exist between fetal adenomas of the thyroid and hyperthyroidism. Zak has reported a tumor of the hypophysis occurring in a patient 52 years of age, which was composed almost entirely of eosinophil elements but was unassociated with acromegaly.

Creutzfeldt in a recent article dealing with lesions of the hypophysis gives the following statistics concerning the changes found in the hypophysis in 56 cases of acromegaly:

No. Cases.	Character of Lesion.	Per Cent.
5	Without hypophyseal changes or changes not mentioned	8.9
15	Sarcoma	26.7
12	Hyperplasia	21.4
8	Struma	14.2
12	Adenoma	21.4
4	No anatomic diagnosis	7.1

It will be seen from the above table that hyperplasia, struma or adenoma of the hypophysis was found in 57 per cent. of the cases of acromegaly. It is quite probable that most of the cases regarded as sarcoma were actually adenomas of the hypophysis, the possibilities of error in anatomic diagnosis having been previously discussed. It seems probable, then, that definite evidence of increased hypophyseal function can be found in about 83 per cent. of these cases of acromegaly. The constancy of hypophyseal changes and the frequency with which the same lesion is repeated cannot be overlooked in determining the etiologic relationship between hyperpituitarism and acromegaly. This relationship is still more strikingly emphasized by the improvement noted by Cushing and Hoehenegg in acromegalic patients following partial hypophysectomy.

CONCLUSIONS

1. The most common tumor of the infundibulum is that developing from inclusions of the cranio-pharyngeal duct. These may be cystic or solid. They are more frequently associated with Fröhlich's syndrome than any other type of intracranial tumor.

2. The most common lesion of the hypophysis in cases of acromegaly is the struma or adenoma of the anterior lobe. In the early stages of the disease, the course having been interrupted by an intercurrent affection, a hyperplasia of the anterior lobe may be found.

3. In cases of acromegaly in which there is no enlargement of the hypophysis careful histologic examination as to the character of the cells should be made. In cases of acromegaly in which no gross or microscopic changes are found in the gland the examination should not be regarded as complete unless a careful search for and study of the pharyngeal hypophysis has been made.

4. Tumors developing from the pars intermedia are rare, but three cases being reported. Two of these gave rise to no symptoms, the tumor being discovered during routine post-mortem examinations. Cushing's patient died as the result of increased intracranial pressure. It

should be noted in this case that the patient was excessively obese.

5. It is probable that some of the tumors arising from the pars intermedia may have been regarded as peculiar types of adenoma or sarcoma.

6. Stains which differentiate granules should be used in examining all growths of the hypophysis in order that incorrect anatomic diagnosis may be avoided, for hypophyseal cells tend to reproduce the morphology of a sarcoma when proliferating. The specific granules will differentiate the hypophyseal cells from those of a sarcoma.

7. Failure to recognize the morphology of the different elements in the hypophysis and their relation to tumor formation accounts for much of the confusion concerning the relation of the gland to acromegaly.

THE ESSENTIAL DIFFERENCES BETWEEN THE PHYSICAL FINDINGS IN CHILD- HOOD AND ADULT LIFE

A CLINICAL AND ROENTGENOGRAPHIC STUDY*

LOUIS A. LEVISON, M.D.

AND

HARRY DACHTLER

Roentgenologist to Toledo and St. Vincent's Hospitals
TOLEDO, O.

It has not been our purpose to compare seriatim all the physical findings of infancy and childhood with those in later life, as this would be both long and without advantage. This paper originated rather in the difficulty which we experienced and which has doubtless been duplicated by every diagnostician, in interpreting properly many of the physical findings of childhood, even in normal children. This interpretation of signs in childhood might be compared to those in adult life as the examination of a moving train is to the examination of one stationary. There can be no permanency at any stage of the child's development; there can be no entirely definite and satisfactory standard at any age; there can, indeed, be no certainty of what constitutes the norm in a child, as the abnormal is so frequent and the differentiation so delicate.

It would seem that, with such unlimited material in the hands of nearly every practitioner of medicine, with such abundant opportunities for observation, there would be at this time little difference of opinion in regard to many signs in childhood. Yet this is not true. The ideal method of acquiring skill and accuracy in physical diagnosis is by the checking up process of the autopsy table, but this is unfortunate in that it has to do with pathologic conditions. The acquisition of accuracy in physical diagnosis cannot possibly come from observation of others, reading, or lectures, but must be obtained by the individual on the living body. The autopsy control is clearly impossible to the vast majority and, for the reason above mentioned, not entirely satisfactory to the remaining small minority.

The replacement of this control in diagnosis on the unhealthy dead by another control on the healthy living is made possible with the Roentgen examination, a

means that we have used with much satisfaction. The Roentgen ray can never be a substitute for the eye and the hand and the ear, because it is too often unavailable at the time needed; because it is impossible for poor patients in their homes, and for other very obvious reasons. All of the Roentgen work in this connection has been done by one of us. It has been our aim to check up the physical findings; especially percussion findings, with the Roentgen ray and to pay especial attention to a number of points concerning which there is still much discussion and uncertainty.

EXAMINATION OF THE CHEST

The roentgenographic examination of the thorax in infants is difficult. This is particularly true with the orthodiagraphic method. Fortunately, improvements in apparatus and technic allow young children to be examined by means of the teleroentgenographic method with accuracy and dispatch. This has been the method utilized by us. In order to make the exposures within the time limit necessary to secure good results, a tube distance of 1 meter was adopted. Observations made by us showed that, with children at the ages studied (under 12 years), this distance allowed more accuracy than a distance of 2 meters in adults; a distance which has been generally accepted and proved of such accuracy as to replace the orthodiagraph in routine work. All children old enough to stand upright were examined in this position with face to the plate. This method reduces the apparent enlargement of the heart and great vessels to a minimum, so that it can be virtually disregarded. Seventy children under the age of 12 have been studied by us with this method. Our material has been derived from the St. Vincent Orphanage, the Toledo Juvenile Home, and the private practice of each of us.

The general points of difference in the thorax of childhood and adult life are at once distinctive. The younger the child, the greater is the distinction. The shape of the thorax in the new-born is obtusely conical, with the greatest circumference at the base. The circumference decreases gradually toward the upper aperture, but not with a cone-like regularity. The antero-posterior diameter at birth is practically that of the transverse dimension. This cylinder-like chest has a direct bearing on certain physical findings, especially cardiac, to be touched on at another point. The figures of Rauchfuss show that these dimensions change with some constancy as development progresses. The ratio of the antero-posterior diameter to the transverse is as 14 to 18 at the sixth year and as 14.5 to 20 at the twelfth. The sternum in childhood shows a marked difference in position relative to the vertebral column. It may be fully two vertebrae higher in early life, with a corresponding rise of the anterior border of the upper thoracic aperture, with the result that this aperture lies in a more nearly horizontal plane.

The ribs in childhood vary distinctively from their position in after-life. It is this fact which is responsible for the error incurred in considering ribs and interspaces as landmarks comparable to those of adult life. In childhood the projection of the ribs from the spinal column is transverse rather than the oblique direction of later life. A given point on the thoracic wall in childhood would not correspond to a similar point in adult life measured in terms of spinal vertebrae, which is our most fixed and stable means of comparison. The ribs not only project more transversely at

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

their beginning, but continue around the chest without the downward inclination of adult life, resulting in a chest contour resembling the adult chest at the height of inspiration. The transverse direction of the ribs allows more room for the lungs posteriorly and this fact is not without significance in the interpretation of signs under the sternum, where the anterior lung borders constitute a factor. The epigastric angle in consequence of the horizontally placed ribs is, of course, more obtuse than in adult life.

The examination of the chest in childhood is all too frequently by auscultation alone. This is due to the difficulty of obtaining satisfactory results from percussion. The great number of methods recommended for accurately outlining the thoracic organ borders attest the more or less unsatisfactory nature of most of them. There is a practical unanimity of belief in the greater advantage of light over strong percussion, but a considerable difference of opinion as to the degree of lightness. Strong percussion will not uncommonly produce a tense, involuntary, muscular contraction, which tends to cloud the actual note of the underlying structures. Hein showed by his experiments that with light percussion he could demonstrate the presence of airless organs through layers of lung tissue up to 1 cm. thick. In reality, the edges of the lung which cover the heart in children never reach this thickness.

It is not at all probable that one will percuss too lightly in children, so the care should be taken in the other direction. That form of percussion known as Goldscheider's or "threshold percussion" is peculiarly adapted to children. Here the lightest stroke possible is employed and the note produced is at the extreme limit of audibility. The percussion stroke by this method does not disturb tissue structures except under the percussing finger. No one can be sure that the tone produced by ordinary percussion is not a transmitted one or is influenced by adjacent organs or structures. Ideal conditions of quietness are absolutely essential in order to hear and to interpret properly a note at the extreme limit of audibility. Practically such a degree of quietness is not always attainable and to use Goldscheider's method under other conditions means failure. It is difficult to understand from purely theoretical reasons Goldscheider's statement that by this method only the axial waves produced in the direction of the finger stroke are perceived, and that all divergent, radiating waves are imperceptible.

The vibrations produced by a percussion stroke of the body wall, the underlying tissues, and contained air does not extend only along one line and that a prolongation of the axis of the percussing finger, but radiates, in all directions. Any area of resonance or tympany that is reached by these centrifugal lines of vibration may mask, cloud or disturb a non-resonant note produced immediately under the percussing finger. It is on account of this fact that we should tend to percuss a point rather than an area. In order to do this, the smaller the pleximeter area in contact with the body wall, the greater is the likelihood that the note produced will be from the point or area in question and will not include a transmitted sound. The Plesch method of percussing on the terminal phalanx of the finger is good theoretically, if it does not involve an unnatural over-extension of the terminal interphalangeal joint, resulting in an uncomfortable and difficult position. It happens, not uncommonly, that such a method of percussing cannot be carried out without lavishing such a degree of atten-

tion on the art of percussion *per se*, that the interpretation will seriously suffer thereby. The technic of percussion becomes to all good diagnosticians, a second nature, and one should be entirely unconscious of the stroke, giving his entire attention to the note produced and the degree of resistance encountered. It is questionable if one who has to weigh the individual percussion stroke can interpret the note accurately. The average clinician learns his percussion technic on adults and neglects, or is unable, to change to another method; it is necessary that one should change with children, and still be unconscious of the change.

It is very doubtful if a single method of percussion is applicable to every one. Certainly, different clinicians get equally good results with different methods. Other things being equal, the smaller the pleximeter finger area is in contact with the body wall in children, the better. This is true, especially in children, because of the greater vibration than in the adult from a blow of equal force. There are a number of factors concerned in this—the thinness of the chest wall, the absence of complete ossification in the costal cartilages, and the greater delicateness of the bony framework. We have found that in extending the last two phalanges of the pleximeter finger on the body wall, it is possible to exert the greatest pressure, comparatively speaking, directly under the terminal interphalangeal joint and still to allow the finger to rest lightly in contact with the body wall. This preserves the natural finger position and has been found satisfactory.

There are many points of difference in gross anatomy between childhood and adult life, which have a direct bearing on the differences in the physical signs. The incomplete development of the heart and lungs, the greater relative size of the thymus, the different position of the diaphragm, the differences in the thoracic wall, all have their influence on the diagnostic findings.

EXAMINATION OF THE THYMUS

The thymus gland is a structure producing in infancy and childhood physical signs which are essentially different from those in adult life. This is an instance in which these differences are due to a complete or almost complete obliteration of an anatomic structure in the change from childhood to adolescence. There has been an interesting difference of opinion among anatomists concerning the thymus, which is well illustrated by the extremes of size given, varying from 2.0 gm. to 31 gm., a variation that is difficult to harmonize with normal body differences. A partial explanation at least may be found in the inability of anatomists to secure normal infants for anatomic measurements. The thymus mirrors or reflects in considerable degree the general nutrition of the child. Poorly nourished children, or those dying after prolonged infections or wasting diseases usually show a small thymus. Friedleben gives the following figures of average thymus weights:

Weight at birth.....	14.3 gm.
1 to 9 months.....	20.7 gm.
9 to 24 months.....	27.3 gm.
2 to 14 years.....	27.0 gm.
15 to 25 years.....	22.1 gm.
25 to 35 years.....	3.1 gm.

The examination of the thymus for physical signs is difficult and very often unsatisfactory. Inspection does not show anything and palpation shows but little. Auscultatory help is questionable and our methods fall back on percussion alone. The dulness produced by the

thymus has never been in our experience more than a slight diminution of resonance. The demarcation of borders is very unsatisfactory when the percussion note is not distinctly dull. The differentiation of this diminished resonance is peculiarly difficult on account of the close association and relation with the sternum, great vessels of the thorax and occasional enlarged bronchial glands. Typical cases show, according to Blumenreich, an area of diminished resonance that is roughly triangular, with blunted angles. The base of this triangle is a line drawn between the lower edges of the clavicular extremities. The tip of the triangle lies on the sternum on or more often below the angle of Louis. Lines drawn slightly convex outward, which connect the extremities of the base line with the apex, will map out the lateral edges of diminished resonance. These lateral lines, however, are not symmetrical. The left edge of diminished resonance usually projects considerably over the left sternum border, but not so on the right. A large thymus manifests itself by an extension of the area of diminished resonance downward and to the left rather than to the right. This enlarged area tends to merge with dulness produced by the heart and great vessels.

We have given especial attention to the thymus in our roentgenographic work. Basing conclusions on our seventy examined cases, we believe that reports of other investigators that it is possible to determine the normal thymus shadow by the use of the Roentgen rays, are erroneous. Hochsinger states that "the middle shadow thrown by the thymus under normal conditions rests on the shadow thrown by the heart, just as the slender neck of a bottle is fixed on the body of the bottle." This bottle-neck shadow, due to the thymus and heart, has come to be a sort of fixture in medical literature, mainly by reiteration and quotation. The roentgenographs published by Hochsinger are far from conclusive. It is to be remembered that the thymus shadow from its anatomic location merges with the shadow produced by the sternum, spinal column, and particularly with the great thoracic vessels. A definite enlargement of the thymus could not be differentiated accurately unless the thymus enlargement extended laterally beyond the great vessels, which is improbable in consideration of the great relative width of these structures in childhood. Anatomic studies have, but uncommonly, shown such a degree of hyperplasia. Furthermore, it is entirely probable that a thymus enlargement may extend antero-posteriorly, rather than laterally, rendering the delineation still more difficult.

A broadening of the shadow above the heart is much more probably due to the thoracic vessels than to an hyperplastic thymus. We have not been able to demonstrate this broadened shadow above the heart, even in cases which gave strong clinical evidence of hyperplasia of the thymus. This has also been the experience of Lange in four cases, in which thymus enlargement was definitely diagnosed clinically.

EXAMINATION OF HEART

The heart in childhood is situated nearer the sternum than in adults, and in the developmental change from childhood to adolescence, there is a gradual displacement to the adult position. This situation near the sternum contracts the retrosternal space between the sternum and the anterior layer of the pericardium. The heart is held in this position by the shorter and tighter inferior and superior sternopericardiac ligaments. This

space can be demonstrated distinctly with the Roentgen ray in lateral views. The more transverse or horizontal position of the heart in childhood results in distinct differences in percussion boundaries. In relation to the bony structures, the heart occupies a higher position due to the higher situation of the liver, the position of the diaphragm, the shorter and broader great thoracic vessels. The attachment of the child's heart to adjacent structures is less firm, resulting in greater mobility and easier displacement. The size of the child's heart is relatively large. This is likewise true of the great arteries of the thorax. The heart and the arterial tree gradually decrease in relation to the body weight as the child passes on to adolescence. Baginsky states that the ratio between the heart volume and lumen of the aorta ascendens is as 25 to 20 in the child; 140 to 50 preceding puberty, and 290 to 61 immediately following puberty, during which latter time the heart increases in weight markedly. Anatomists are agreed that the growth and development of the heart occur in an irregular manner. Two points are generally conceded, namely, that the size of the heart is large in relation to the body weight during the first year of life and again at puberty. Von Dusch asserts, however, that in addition to these periods, there is another period of growth from the third to the seventh year, during which the heart becomes again relatively large. Vierordt states (quoted from Hochsinger) that the heart weight is 0.89 per cent. of the body weight during infancy, but only 0.52 per cent. during adult life. The marked difference between the thickness of the ventricular chambers and the heart weight is important anatomically, but does not influence the physical findings as much as the ratio between the size of the great vessels at the base and the heart. This relatively large volume of the great vessels has its bearings on the percussion borders of the heart, and likewise on the differentiation of the heart, great vessels and thymus from one another with the Roentgen ray.

There are a number of factors which make the percussion of the child's heart a difficult procedure. One cannot fairly compare the cardiac percussion dulness in the child with that in the adult. The changed position of the heart in early life, its more horizontal and higher situation results in a different standard of comparison, even after the relative differences in the size of the body has been taken into consideration. This altered situation of the heart brings the right edge of dulness further to the right, a fact which is often ascribed to a disproportion in size between body and heart in childhood. There are particular reasons which make the determination of each heart border peculiarly difficult in the child. The upper heart border has to be demarcated from the great vessels of the thorax, which in the child are relatively large in size and volume, from enlarged bronchial glands, an enlarged thymus, and the dull area described by Hamill. The left cardiac border is difficult of determination for two reasons chiefly. There is a tendency, fixed naturally and by habit, to percuss out the left heart border in children, as well as in adults, with a percussion stroke having its axis perpendicular to the body wall. The more or less circular or cylindrical shape of the child's chest results in a considerable degree of distortion of the cardiac outline, which can be obviated by making the percussion stroke for the left border parallel to that for the right border, regardless of our tendency to percuss at the right angle to the body surface. An impairment of

the note along the left edge of the heart, especially along the lower part, may result from gastric or intestinal dilatation, even when it is not apparent. The right border of the heart is peculiarly difficult to map out, because the higher position of the liver on the right side may influence the normal resonance of the lower right front. Two other factors influence the position of the right border, the diminished resonance normally obtained over the sternum and, secondly, what we believe to be an actual slight degree of normal variation, due to the greater and freer mobility of the child's heart.

There is a considerable difference of opinion as to the advisability of attempting to percuss out the superficial heart dulness or the actual size of the heart. In adults, the percussion of the actual borders of the heart is so difficult that it is not ordinarily attempted. In children, better results can be obtained with the actual heart borders. This does not imply that the determination of the size of the heart in children is easy, either relatively or absolutely. On the contrary, the reverse is true, and to map out the heart percussion borders accurately is truly a difficult procedure. We know from the numerous experiments of Oestreich on the cadaver that the superficial heart dulness in adults can be determined with great accuracy. Superficial dulness maps out simply the lung borders and not at all the shape or size of the heart. It is stated by Mayer and Milehner that there is often a moderate degree of emphysema of the lung edges in young children, which may lead to erroneous conclusions. There are many more objections against the superficial dulness in children than in adults. There are greater numbers of functional disturbances and constitutional anomalies affecting the child's heart than the adult and the superficial dulness helps in no way, or at least but slightly, to determine these. Such disturbances of childhood, which have been described, are the so-called adenoid heart, the *cœur de croissance* of Germain, the relatively small heart of Bouchard, the heart of the narrow-chested of Kraus (*Herz der Engbrustigen*), the constitutionally weak heart of Martius, the dilatative heart weakness of Neumann, and functional disturbances after acute infections.

There are still more important reasons for determining the actual heart size in children. In adult life that part of the heart covered by the chest wall area from the fourth to the sixth costal cartilage and rib is fixed, determined and stable. In childhood this area is changing with the body development, but not with a definite rate of progression. It is impossible at any given age to tell how far the superficial heart dulness is due to the heart itself, or to natural changes of development, which are continually occurring. Likewise, in adults, the relationship between heart and the great vessels, thorax, and mediastinum, are fixed and definite. Not so, however, in childhood, as the bony thorax is constantly developing by a chondro-epiphyseal growth which widens the thorax and, as a result, any bony landmark used to express heart size in children is indefinite and variable.

It is because of this lack of definitely fixed bony landmarks that we should use actual figures of measurement for describing heart borders rather than the relation to a certain variable rib or arbitrarily drawn line. This is true particularly of the lateral borders, if not of the upper. This is one of the points which we desire to emphasize most strongly, and the lack of such

custom has, in our opinion, been one of the causes for the present great difference of opinion concerning heart borders in children. A mapped-out area of cardiac dulness expressed in centimeters from the fixed mid-sternum, a line not subject to variations due to irregular and varying degrees of growth, expresses the heart size without equivocation or possibility of misinterpretation. Sahli's measurements in terms of relation to ribs and nipples may be taken as average boundaries. He gives the superficial area of dulness as follows: above, the upper border of the third interspace; left border, a line drawn between the parasternal and mammary line; right border, the left border of the sternum. The deep heart borders are as follows: above, the second interspace or the lower border of the second costal cartilage; left border, at or beyond the mammary line; right border, at the right of the parasternal line or beyond. These borders are for children, not infants or very young children. Expressed in centimeters, Sahli's figures are as follows:

Age	Widest diameter.	Right.	Left.
2 to 6 years . . .	10.5 cm.	3 cm.	7.5 cm.
7 to 12 years . . .	11.5 cm.	3 cm.	7.5 cm.

Troitzky, summing up various measurements, arrives at the following averages. He has, however, taken the width of dulness at the upper part of the sternum and not at the level of the nipples.

Age	Width.	Right.	Left.
2 to 6 years . . .	7.5 cm.	2.5 cm.	5.0 cm.
7 to 12 years . . .	9.0 cm.	3.0 cm.	6.0 cm.

This shows the lack of uniformity, a desideratum which is much to be desired, if the average clinician or general practitioner is to have recourse to an accepted standard.

Reyher's figures with the orthodiagraph are as follows:

Age.	Width.	Right.	Left.
2 to 6 years . . .	8.2 cm.	3.0 cm.	5.5 cm.
7 to 12 years . . .	11.1 cm.	3.5 cm.	7.6 cm.

In the seventy cases which we have rayed by the teleoroentgenographic method in heart measurements in centimeters were as follows:

Age.	Width.	Right.	Left.	Distance to left of median line of broadest vessel shadow.
3 months	5.4	2	3.4	3.0
2 to 6 years	7.0	2.5	4.5	3.0
7 to 10 years	9.5	3.5	6.0	4.0
11 to 12 years	10.5	3.5	7.0	4.0

It has not been possible for us to compare the roentgenographic measurements of each of these cases with the measurements obtained by heart percussion, but the average figures obtained by us show that our greatest percussion error has been in determining the breadth of the great vessels of the thorax. The right and left borders of the heart can be determined quite accurately by percussion as checked up by the Roentgen examination. The greatest source of error in determining the left border can be overcome, if the axis of the percussion stroke is kept parallel with the axis of the right border percussion stroke and is not made at right angles to the body wall. These figures show what is rather unexpected and surprising, namely, that it is the right border in children that is most accurately demarcated by physical diagnosis and not the left.

EXAMINATION OF LUNG

It is very desirable that one should have a clear understanding of the factors underlying lung percussion sounds, if their interpretation is to be accurate. There is still some difference of opinion concerning the

part played by the thoracic wall in the percussion sound. It is not to be denied that the vibration of the thoracic wall constitutes at least a partial factor of the lung sound. The difference in flexibility and elasticity between the child's thoracic wall and that of the adult accounts in large measure for the normal difference in sound in childhood and adult life. The other factor, the vibration of the bronchial air column, is not subjected to so much difference at the two periods in life, except in the amount of air and the size of the column. If the sound were proportional to the amount of vibrating air alone, with modification by other factors, there would be greater resonance in adult life than in childhood, which is not the case. On the other hand, the great influence of the thoracic wall factor is shown by the change of note in the child when the lateral lying-position is assumed and the chest wall is in contact with the bed. The resultant diminution of thoracic wall vibrations produces a distinct dulling of the percussion note. The same great flexibility and elasticity of the thoracic wall in childhood explains the less resonant percussion note at the end of deep inspiration in children old enough to breathe as directed. Full lung expansion increases the tension of the chest wall, lessens its elasticity and vibratory power, and, notwithstanding the greater amount of air in the lung at the height of inspiration, it is not great enough to counterbalance the diminution in chest wall vibration.

The normal lung sounds in childhood vary from those in adult life, even in other respects than the degree. Posteriorly, the percussion sound in childhood is more resonant than in adult life. This is due to several factors, including the more posterior position of the lung in childhood, relatively speaking. There is a greater volume of air-containing lung tissue nearer the surface of the dorsal body wall. It follows from this that the anterior edges of the lungs should be further separated, relatively, than in adults and this is the case. This is likewise one of the anatomic facts explaining the greater exposure of superficial heart dulness in children. Laterally, the thoracic resonance approaches that obtained over the infraclavicular region anteriorly, until one passes below the sixth rib.

The area of dulness under the inner third of the left clavicle, described by Hamill, has been carefully looked for in every case examined by us, and especial attention has been paid to this area on x-ray plates. Hamill states that, contrary to text-book teaching, it is the left and not the right front which shows a relative impairment of resonance. This area of dulness is indefinite in shape and size, but is to be found, according to Hamill, "beneath the inner third of the clavicle, which (area) sometimes extends outward to the mid-clavicular line, and always downward until it fades into the cardiac dulness." This area of dulness is "constantly present up to the age of 9 or 10 years." Hamill does not give an entirely satisfactory reason for this area of relative dulness, but believes it has to do with the more posterior position of the lungs in childhood and the more exposed condition of the large thoracic vessels. It has not been possible for us to determine this area of dulness as described. We have encountered impaired resonance over this region, but not with sufficient regularity and certainty to consider it a normal condition. According to the studies of Blumenreich mentioned above, there is an asymmetrical area of impaired resonance, reaching farther to the left than to the right, but only up to the sixth year. The location of that part of

the thymus dulness to the left of the sternum and under the inner end of the clavicle corresponds to a part of the area described by Hamill, although it does not extend outward or downward so far. Again, the more posterior position of the lungs in childhood applies equally to both sides, and the measurements by Feer show that at the age of 4 to 5 the right chest circumference exceeds the left by as much as 1.5 cm. The possibility of enlarged bronchial glands necessitating a differentiation will be touched on below. It is our belief, after a careful investigation of this point, that there is no normal impaired resonance directly under the left clavicle. It has been our experience, however, that dulness from the heart and great vessels rises to the upper edge of the left second costal cartilage in young children, and that between this point and the clavicle there is an area, which, while normally resonant to the lightest percussion, may appear relatively impaired in resonance, if the percussion stroke is at all strong. The high position of dulness at the second left costal cartilage in young children is in full harmony with the results obtained with the Roentgen examination. Furthermore, in the area between the great vessels and the clavicle, the Roentgen examination has not revealed anything which could reasonably account for impaired resonance over this area. It is much to be desired that this observation of Hamill be further confirmed. It would seem that such an area of impaired resonance at such an accessible point would not have escaped general observation and acceptance. The diagnostic significance of relative dulness at this point is considerable and the differentiation from the various pathologic conditions that can cause such dulness is of sufficient importance to merit close observation by others.

EXAMINATION OF BRONCHIAL GLANDS

The great frequency of enlarged bronchial glands in childhood makes a trustworthy method of diagnosis very desirable. No method of physical diagnosis can compare with the Roentgen rays. The value of the hitherto described methods of diagnosis have been, as a rule, dependent on the size of the glandular mass. The anatomic landmarks of the bronchial glands are the lower end of the manubrium sterni anteriorly and the fifth dorsal vertebra posteriorly. Dulness or impaired resonance in this region would be therefore in the region of the thymus, the impaired resonance produced by the sternum, the great vessels of the thorax, and the area of Hamill. Localized patches of dulness in the second interspace suggests enlarged bronchial glands, and the tendency of this form of dulness is to extend transversely. It has been advised that attempts to demonstrate such patches of bronchial gland dulness should be made at the end of forced expiration. Curschman and Schlager found dulness due to enlarged bronchial glands in adults, but this is certainly an uncommon finding. There have been a number of signs described to aid in the diagnosis of enlarged bronchial glands, but which have only a secondary value. Camp described relative dulness over the spinal processes of the fifth and sixth thoracic vertebrae. Petruschky's spinalgia is an area of tenderness between the shoulder-blades, but has not been found to be of great value. The better known sign described by Eustace Smith is not trustworthy. This sign consists in a venous hum audible over the manubrium during hyperextension of the neck. Thus, if the child in the erect posture bends the head backward so that the eyes look toward the coil-

ing, the hum will appear in the positive cases, owing to the compression of the left innominate vein between the manubrium and the glandular mass. The great frequency of venous hums in children without glandular enlargement render the interpretation of this sign particularly difficult.

CONCLUSIONS

The following conclusions are drawn from this work:

1. The Roentgen examination affords an unexcelled method of controlling the results obtained by physical diagnosis.
2. The teleroentgenographic method reduces the error by distortion to a negligible quantity and is well adapted to routine work.
3. The anatomic location of the normal thymus renders its differentiation by means of the Roentgen rays improbable.
4. The demarcation of heart-borders in terms of bony landmarks does not offer a fair comparison with adults, owing to the continual change in the development of the bony structures.
5. Absolute heart dulness in children can be quite accurately determined by very light percussion, and the results confirmed by the Roentgen rays.
6. The relatively great volume of the great thoracic vessels in young children offers the greatest difficulty in determining the size of the heart by physical methods only.

7. Extremely light percussion has not given us normal impaired resonance between the upper borders of the great vessels and the clavicle. The Roentgen examination has confirmed the absence of a density of tissue which would produce such dulness.

Sparks Building, 237 Michigan Street.

ABSTRACT OF DISCUSSION

DR. FRANK SMITHIES, Ann Arbor, Mich.: From my experience in teaching physical diagnosis to medical students I have long felt the need of such a piece of work as this. The literature abounds in generalities. There is little said in the text-books or in monographs with respect to the findings spoken of. I was particularly interested in the roentgenographic findings in respect to the thymus. Three cases of thymus death have impressed on me the need of thorough physical examination of the child's thorax before such a simple operation as one on the tonsils or adenoids. In two cases the physician had entirely neglected the examination of the child's thorax except putting the stethoscope over the visible heart beat and saying that that organ was all right. Sometimes a radiograph will give admirable information in regard to the thymus, but it has been my experience that the thymus could be mapped out very readily in infants and in the newborn when the attempt is made. I urge on every one to make careful examination of the thorax before operating on children. The heart is infrequently examined and, where it is examined, unless done systematically, the findings are practically worthless. As to the findings in the mediastinal region, I think often anomalous conditions of the heart and blood-vessels can be traced to glandular conditions in the mediastinum.

Etiology of Intussusception.—H. J. Morgenthauer states that the essential cause of intussusception is irregular peristalsis, particularly atony of one part with increased activity of adjoining parts of intestine. It may thus follow any limited, sudden, and severe peristalsis.—*Am. Jour. Obstet. and Dis. of Women and Children.*

PATHOLOGY AND BACTERIOLOGY OF ACUTE ANTERIOR POLIOMYELITIS *

H. E. ROBERTSON, M.D., AND A. J. CHESLEY, M.D.
MINNEAPOLIS

I. PATHOLOGY

A review of the literature shows records of about 100 autopsies on cases of poliomyelitis, nearly one-half of which were performed years after the acute attack.

Our studies include material from six autopsies performed on cases occurring in the Minnesota epidemic of 1909. In the article the cases are reported in detail.

The process as a whole follows a definite and specific course. Whatever may be finally shown to be the agent of infection, its "optimum locus" is in the perivascular lymph channels of the anterior portions of the cord, especially those located in the gray matter. From this site the reaction spreads on the one hand to the surrounding tissue spaces of the gray matter and on the other to the lymph channels of the white matter and pia, often involving the posterior portions of the cord.

CONCLUSIONS

1. Acute anterior poliomyelitis is a specific infectious disease characterized pathologically by general toxemia affecting the parenchyma of the heart, liver and kidneys and the lymphoid tissues of the body, but spending itself locally on the structures of the spinal cord.
2. Grossly the cord is congested and on transverse section shows softening and often hemorrhages in the gray matter of the anterior horns.
3. In the cord the infectious agent is located in the perivascular lymph channels of the anterior portions, especially invading the gray matter, but extending to the white matter and pia and occasionally the posterior horns. The brain stem and basal ganglia may be involved. In the cord the medulla and cervical and lumbar swellings are particularly affected.
4. The characteristic lesion consists of collections of cells in the perivascular and pial lymph channels and tissue spaces of the anterior horns. Of these cells the polymorphonuclear leukocytes appear early and are relatively few in number. They are soon displaced by endothelial cells arising from proliferation of the lining endothelium and lymphocytes coming from the blood and lymph streams.
5. Edema of the interstitial tissue and degeneration and destruction of the ganglion cells are always present.
6. The vessels are congested, their walls degenerated, and the capillary branches in the gray matter irregularly distended and often ruptured, giving hemorrhages, which always intensify markedly the amount of destruction. Thrombosis was not observed.
7. Early degeneration of nerve fibers from the anterior roots is a constant feature.
8. Stains for micro-organisms were uniformly negative.

II. BACTERIOLOGY

Specimens from twenty cases of poliomyelitis were examined by the laboratory division of the Minnesota State Board of Health during the 1909 epidemic.

The cultural and morphologic characteristics of Geirsvold's diplococcus were found to coincide with the description given by Drs. Fox and Rueker.

Geirsvold's diplococcus was found in purity in the spinal fluids from seven cases (two died, see Dr. Robertson's Cases 1 and 3), and also in cultures from the blood, mouth, lung, spleen, kidney, middle ear and brain substance of Case 3.

The tests to determine the pathogenicity of these pure cultures confirmed the opinion of other observers that Geirsvold's diplococcus is not a causative factor in poliomyelitis.

* Authors' abstract of a paper read before the Sections on Nervous and Mental Diseases and on Pathology and Physiology of the American Medical Association, St. Louis, 1910. The complete article will appear in the Transactions of the Sections and in the Archives of Internal Medicine.

The spinal cords of thirty-eight animals experimentally infected failed to show specific lesions of poliomyelitis though in some animals motor disturbances developed which might have been mistaken for the symptoms of poliomyelitis. The presence of specific lesions was regarded as the crucial test.

We believe that symptoms of inoculated animals must be supported by pathologic findings to have any value as experimental evidence.

THE SURGICAL TREATMENT OF INFANTILE SPINAL PARALYSIS *

DAVID SILVER, M.D.

Professor of Orthopedic Surgery, University of Pittsburg
PITTSBURG, PA.

To one who thoroughly appreciates the pathology of anterior poliomyelitis the surgical treatment of the chronic stage of this affection yields satisfactory and gratifying results. A certain amount of irreparable damage has been done the spinal cord, in consequence of which the muscular power of the affected part has been correspondingly diminished. One may not hope to restore such a member to its normal condition; one may hope, however, to overcome deforming tendencies resulting from loss of muscular balance and to establish conditions such as will enable the part to functionate in the most efficient manner permitted by the existing degree of paralysis.

OBJECTS OF OPERATION

The objects of operation in this affection are two:

1. Improvement of form in the deformed member (by forcible correction, tenotomy, fasciotomy, myotomy, osteotomy, wedge-shaped excision of bone, and bone excavation).
2. Improvement of function in the non-deformed, or corrected, member.
 - A. Through restoration of power to the paralyzed muscle (by nerve anastomosis).
 - B. Through restoration of muscle balance (by muscle and tendon grafting and transplantation).
 - C. Through securing greater stability in the paralyzed member (by arthrodesis, astragalectomy, silk ligaments, tenodesis, fasciodesis, and removal of skin flaps).

I. IMPROVEMENT OF FORM IN THE DEFORMED MEMBER

It is a deplorable fact that, while deformity is generally conceded to be, as a rule, preventable by the early, proper and persistent use of passive motion and retention apparatus, the majority of patients consulting the orthopedic surgeon for this affection present malpositions of greater or less degree.

Deformity is most complex in its causation. One of the most essential factors is loss of muscle-balance resulting from unequal distribution of paralysis; it is well recognized clinically that a generally affected part may retain an approximately normal form, while paralysis of a single muscle or group of muscles, as, for example, the peroneals, may give rise to a severe malposition. To this loss of balance, which through unopposed muscular action permits of gradual lengthening of the affected and shortening of the unaffected muscles, are added the effects of gravity, of habitual posture and of functional use; finally structural adaptation takes place, fixing the part in the deformed position. When a malposition has been allowed to persist for some time, whether structural

adaptation has taken place or not, a new factor, of great importance in the proper estimation of the degree of the paralysis, is added: this is the overstretching of the weakened muscular tissue. That damaged nerve cells may recover sufficiently to functionate, but in the meantime the affected muscles become incapacitated by overstretching and atrophy from disuse, is a fact which, though well known to specialists, does not seem to be recognized by the mass of the profession and which certainly is very frequently disregarded by all in judging the results of operative measures. It is impossible by any tests at our command to judge accurately of the power of such overstretched muscles²; only by maintaining them in a position of maximum relaxation for a sufficient time to permit retraction to take place can we be definitely certain of their condition. Hence, any operation for the correction of deformity necessarily includes long-continued retention in an overcorrected position, and this, furthermore, must obviously precede measures for the improvement of function.

For any cases which have proved intractable to passive motion and mechanical measures a variety of surgical procedures—forcible correction, division of muscles, tendons, ligaments and fasciæ, and operations on the bones—are at our disposal, the choice of which will vary according to the mechanical conditions to be met, a combination of the various procedures being, as a rule, required.

Forcible Correction.—Forcible correction, performed manually or with the aid of various forms of apparatus, yields a uniform stretching of all contracted soft parts, permits the lengthening of deep-lying structures not readily accessible to the knife, and restores the muscle belly to its former length, instead of causing a further shortening and so a further decrease in excursion, as does simple division. With increase in the amount of force used, however, there is increasing danger of injury to soft parts and bones; moreover, under certain conditions one deformity may be increased while another is being corrected. One example of this will suffice: Given a case of talipes equinovarus, any amount of force applied to the sole can have no other than a beneficial effect on the contour of the foot, while in talipes equinovarus, on the contrary, the force used to correct the equinus will necessarily tend to increase the valgus; hence, in this instance, operative lengthening of the tendo Achillis would be preferred.

Tenotomy.—While subcutaneous tenotomy after the original method of Stromeyer, when practiced in suitable cases, ordinarily yields entirely satisfactory results, yet in infantile spinal paralysis there are certain considerations which favor the choice of other methods. In stating these considerations the tendo Achillis only will be mentioned, as it is the one most frequently requiring division.

Simple tenotomy does not permit control of the extent to which the tendon is lengthened, yet this is a matter of considerable moment, for the strength of a muscle depends very largely on its tension, its strength being markedly decreased when the normal tension is lost, since a certain amount of force must be expended in restoring normal tension before joint movement can take place. Hence, in cases of corrected paralytic talipes equinus in which the tendo Achillis has been divided by the old method, it is not uncommon to find the power

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

2. Tubby, A. H.: Recent Surgical Methods in the Treatment of Certain Forms of Paralysis, *Brit. Med. Jour.*, March 1, 1906.

of plantar flexion much diminished, so that the patients are unable for months or even years to stand on the toes.³ In an analysis of eighteen paralytic cases in which simple division of the tendo Achillis had been performed from three to eight years before, Hibbs⁴ found serious modification of the function of the calf in eleven; he attributes this to the following factors: First, shortening as a result of the deformity; second, further shortening as a result of the tenotomy, and third, still further shortening from yielding of the bond of union between the divided ends. The control of the amount of lengthening is, therefore, advisable, and this may be secured through lengthening by the open method or by means of the subcutaneous method of Beyer.

Operations on the Bones.—Should bone changes have become so marked that forcible correction and division of soft parts are not sufficient to overcome deformity, this may still be accomplished through osteotomy, wedge-shaped excision, or bone excavation (Ogston's operation⁵).

While the procedures thus far discussed have for their primary object improvement of form, they necessarily contribute through this to improvement of function, and, when combined with the judicious use of apparatus and muscle development and training, will yield in many cases such satisfactory results that no further operative treatment will be indicated.

II. IMPROVEMENT OF FUNCTION IN THE NON-DEFORMED OR CORRECTED MEMBER

A. Through Restoration of Power to the Paralyzed Muscle (by Nerve Anastomosis)

The restoration of normal nerve impulses to the paralyzed muscle or muscles by means of nerve anastomosis would naturally be the operation of choice were it generally applicable to this affection. While the operation must still be regarded as in the experimental stage as regards anterior poliomyelitis, yet enough has been done to justify certain conclusions.

The operation has here evidently a more limited application than at first supposed. It is ten years since nerve anastomosis was first used in anterior poliomyelitis and five years since the subject was presented before this Association;⁶ yet the successful cases available in literature are not numerous, in many, as is so often the case, the reports being made too early for the final results to be known. The reason for this limited field is to be found in the fact that the paralysis is rarely confined to a muscle group supplied by only one nerve-root or spinal segment, but is in the large majority of cases spread over several spinal segments, and so no nerve or nerve-root anastomosis can be beneficial. For a case to be suitable the lesion must affect an entire nerve-center, while other centers remain free.⁷ Hence, cases in which the operation is indicated are undoubtedly fewer than previously considered.

While in the first burst of enthusiasm the procedure may seem to offer the possibility of ideal results, yet a study of the literature indicates that such is not the case. There is admittedly a certain danger of injury to the

healthy nerve, and so, in the event of failure of the anastomosis, a danger that the condition following operation may be worse than that before: this may result from traumatism at the time of operation, failure of cut fibers to repair, or subsequent impairment from scar formation. Spitzzy⁸ admits that there is a loss in the power-giving nerve, but asserts that it is not permanent. Stoffel,⁹ in operating for restoration of the deltoid chose for the power-giving nerve the branch to the middle head of the triceps, since this could be sacrificed in the event of failure without great loss. Results further fall short of the ideal in that complete restoration of power, so far at least, has not been the usual result: this may be due to choosing a nerve that has itself been slightly affected, to imperfect regeneration in the power-receiving nerve, to injury from scar formation, or to failure of the new center to learn its function.

Early operation offers the best chance of success: the longer the duration and the fewer the signs of life in the affected muscle, the less the chance of recovery, for the muscle finally becomes changed into a fibrous, fatty mass from which restitution to the highly organized nerve-muscle organ is no longer possible.⁶ Four to six months, in some cases nine months, is usually given as the most favorable time, yet operation as early as this is open to the objection that the greatest possible degree of recovery has not yet been attained. Spitzzy, perhaps the most ardent advocate of the procedure, admits that in a few cases recovery might have occurred without the anastomosis.

The newly developing function should encounter as little resistance as possible: hence overcorrection of deformity is a necessity, and this should be performed at a preliminary sitting for the reasons already stated. The combination of correction of deformity, lengthening and shortening of tendons, and even tendon grafting with nerve anastomosis at the same sitting, as has been reported, must be regarded as unscientific, since it is difficult under these circumstances to determine accurately to which procedure improvement is due; where nerve anastomosis is used tendon transplantation should be held in reserve as a secondary operation in the event of failure or of partial success of the anastomosis. As a further step in diminishing resistance to the returning function, alcoholization of the nerve-supply to the active opponents has been used by Allison and Schwab.

The upper extremity at present apparently offers the most promising field for nerve anastomosis. The hand, which on account of its highly differentiated function has not yielded such successful results after tendon transplantation as has the foot, seems for this same reason to offer more from a successful nerve anastomosis. At the shoulder, also, where there is no muscle capable of fully replacing the deltoid, conditions are admirable for anastomosis on account of the accessibility of the nerves, and a study of the reported cases shows that the operation in this region has given a relatively high degree of improvement.⁹

B. Through Restoration of Muscle Balance (by Muscle and Tendon Grafting or Transplantation)

The restoration of muscle balance by means of tendon and muscle grafting or transplantation has been so thoroughly tested that its efficacy in the treatment of the

chronic stage of anterior poliomyelitis is to-day beyond question.

Tendon transplantation is no exception to the rule that every operative procedure has its limitations. In the beginning too much was expected of it. It brings no increase of power, except through subsequent muscular development; it merely permits the restoration of an important lost function at the expense of one or more less important ones, thus securing improved action in a part which is still a paralyzed one. If the paralysis be extensive the muscular tissue remaining will not be sufficient to ensure control after balance is restored; hence the method is obviously not applicable to cases of this character except when combined with other procedures.

In the early operations the use of slips of tendons often yielded nothing more than the benefit to be derived from their action as "additional ligaments," since independent action, without which there can be no restoration of function, was rarely obtained; moreover, relapse through gradual yielding of the bond of union or stretching of the weakened receiving tendon was common.¹⁰ Not only have these causes of failure been overcome, but the usefulness of the method has been further extended through the transplantation of whole muscles or of parts of muscles readily divisible (triceps suræ, extensor digitorum, etc.), the use of silk extensions where the tendons are not of sufficient length, and insertion directly into the periosteum or bone at the most advantageous point.

The operative technic is comparatively simple and easily mastered by anyone acquainted with modern surgical methods, but the planning of the operation requires an intimate knowledge of the disease and an acquaintance with human mechanics which can be acquired only by special study. The lack of ability properly to determine the extent and the degree of the paralysis, definitely to estimate the amount of muscular tissue which must be transplanted in order to restore balance, and wisely to combine other operative procedures¹¹ with that of tendon transplantation, fully explain the failure of many surgeons to secure satisfactory results and make it certain that there will always be bad results.

The importance of an extended period of postoperative treatment, including especially protection of the transplanted tendon and careful muscle training,¹² has been so frequently emphasized that it needs no further mention.

As regards the adaptability of the operation to the various regions, the foot is preeminently the domain of tendon transplantation. Here the movements which are absolutely essential are few in number and relatively simple in character; of those required, plantar and dorsal flexion are of first importance, supination and pronation next, while control of the toes is not necessary in shoe-wearing people.³ Hence, it will usually be possible, except where plantar flexion is lost, to secure a normally balanced foot; with lost plantar flexion, however, full restoration is impossible, since the combined strength of all the muscles on the back of the leg is only one-fourth that of the calf (gastrocnemius and soleus). Peroneal paralysis, one of the most common types, which gives rise to a talipes varus or equinovarus, is perhaps the most favorable condition in the foot for transplantation. In mild cases the extensor proprius hallucis may

be transferred to the outer border of the foot, being attached to the cuboid; in marked cases, where the balance is more severely disturbed, the tibialis anticus may be used, if the posticus is normal; in this deformity weight-bearing is an aid in protection against relapse. Talipes valgus is not so favorable as varus on account of the greater power required for adduction and the deforming tendency of weight-bearing. In paralysis of the calf, transplantation alone will rarely do more than prevent a severe degree of calcaneus, but when combined with procedures which enable the muscles to act at a greater mechanical advantage excellent results are secured.¹³

At the knee the final results of substitution for the paralyzed quadriceps have been reported by Böcker,¹⁴ as follows: Transplantation of the biceps and either the semitendinosus or semimembranosus, one flexor being left to prevent a genu recurvatum, gave the best results, almost normal extension with a good and steady gait being secured in most cases; the combination of the sartorius or the tensor vaginæ femoris with the semitendinosus or semimembranosus was less efficient, yielding only 100 to 130 degrees of active extension; the use of the sartorius or the tensor alone gave only moderate improvement, for, while it was possible for the patient to take a few steps on an even surface, apparatus was required for long distances.

In the region of the hip the results obtained by transplantation have so far been slight. Lange¹⁵ has restored the power of abduction in complete paralysis of the gluteus medius and minimus by attaching the upper end of the vastus externus by means of silk strands, arranged in a fan-shaped manner, to the crest of the ilium; three out of four patients so treated were able to lift the leg when lying on the unaffected side, and the gait was greatly improved.

In the hand, where each muscle plays a definite part in the movements of precision here required, the restoration of any lost function can be purchased only at a high price; furthermore, independent action of the transplanted muscle is essential and a longer period of muscle training is required than is the case in the restoration of the coarser movements of the lower extremity. This is sufficient explanation of the lessened efficiency of transplantation in this region. Moreover, on account of the less frequent affection of the upper extremity (one to eight as compared with the upper), opportunity for working out the problems here involved is much less.

The chief attempt in the upper extremity has been to replace the paralyzed deltoid. The difficulties to be met consist, first, in the fact that the different portions of the deltoid have different functions, and, second, in the lack of sufficient muscular tissue for substitution. A portion of the trapezius, the muscle usually chosen, will obviously replace the action of only one part of the deltoid; when this is supplemented by a portion of the pectoralis major a better result may be obtained, but full replacement would seem to be an impossibility. While the operation, therefore, has resulted in considerable improvement, even in some cases enabling the patient to elevate the arm above the shoulder, it falls far short of full function.

C. Through Securing Greater Stability in the Paralyzed Member (by Arthrodesis, Astragalectomy, Silk Ligaments, Tenodesis, Fasciodesis, Removal of Skin Flaps, etc.)

Arthrodesis.—When all the muscles controlling a joint are paralyzed, or in some instances in which the remaining power is not sufficient to ensure control, the operation of arthrodesis, in which the production of an artificial ankylosis is sought, is advisable in order to free the patient of all apparatus or permit the use of a less cumbersome form. Arthrodesis should never be considered until the use of those conservative measures known to be essential have been persisted in for a sufficient time to remove all doubt that the paralysis is permanent, nor should it ever be performed unless it is certain that the expected result will exceed the damage; that is, that the stiff joint will be a lesser evil than the flail joint.¹⁶

The adaptability of the various joints for the operation is in the order of ankle, knee, shoulder, hip, elbow, wrist; operation on the last two is seldom performed.

The operation is peculiarly suited to the ankle, on account of the character of its articulations and its weight-bearing function. It may be performed between the tibia and the astragalus alone, the usual procedure, or with this may be combined arthrodesis between the astragalus and the os calcis,¹⁷ or at the mid-tarsus, the rigidity of the foot being thus varied according to the needs of the case. Bony ankylosis or strong fibrous union is necessary; the latter gives a more elastic foot but carries with it the danger of yielding under use. Operation on patients under 10 is not so likely to yield satisfactory ankylosis on account of the amount of cartilage present in the joints of those under this age.¹⁸ When proper precautions are taken the number of failures is small, and results are both gratifying and permanent, the disadvantages being only those incident to the rigidity; that is, a lack of elasticity in the gait, some difficulty in walking on an uneven surface, and perhaps more early tire. In cases in which there is some muscle power left, but not enough to ensure control of the foot after transplantation alone, arthrodesis of one or the other joint may be combined with transplantation and will be of especial service where only fibrous ankylosis is secured.

At the knee pathologic ankylosis is so common that the advantages and the disadvantages of an arthrodesis of this joint will be apparent to all. The decision should be left to the patient; hence it is best not to perform the operation in children. The condition is so well controlled by apparatus which will permit bending of the knee in sitting that this will usually be preferred, except in the very poor. Where both sides are affected, arthrodesis of one knee only is indicated.

While arthrodesis of the hip is not common, yet under certain conditions it is of distinct value, since muscle and tendon transplantation does not offer much in this region. Where both hips are paralyzed the production of ankylosis in one, which will usually be fibrous, will enable the patient to get on his feet. The method suggested by Albee for operation in osteo-arthritis should be a distinct addition to the technic of arthrodesis of the hip.

The shoulder, when the scapular muscles are unaffected, yields excellent results from arthrodesis. Vul-

pius,¹⁹ who reports twelve cases, had only two failures, and obtained bony ankylosis, which is to be sought, in 60 per cent. The average active motion possible in his case was 75 degrees of forward elevation, 60 degrees of side elevation and 25 degrees of backward elevation; marked improvement in the atrophied biceps and triceps was observed.

Astragalectomy.—On account of its lack of muscular attachment the astragalus is a factor in instability at the ankle, and hence its removal may be indicated. Astragalectomy is one step in Whitman's operation²⁰ for paralytic talipes calcaneus; when this is done the foot can be displaced backward, a procedure which gives improved stability and better leverage for the muscles which are transplanted into the heel.

Silk Ligaments, Tenodesis, Fasciodesis.—The chief objection to the older method of tendon grafting lies, as has been mentioned, in the fact that the improvement gained is often only that due to the action of the grafted muscle as an "additional ligament," independent action not being secured. Following out this idea, several methods have been suggested for directly utilizing the tendons of paralyzed muscles as ligaments, both as a supplementary operation and to obviate the necessity for an arthrodesis. The proximal ends of the tendons have been sutured to the bone (tenodesis of Codavilla-Reiner) or to the fascia (fasciodesis of Vulpinus). The obvious objection to this is that the degenerated tendons will stretch and the method thus give only temporary improvement. The use of silk ligaments, a method at once simple and efficacious, yields a permanent fixation. These silk ligaments are of service in various joints but are in most common use at the ankle, where they are especially valuable in preventing toe-drop. In this condition, which may be taken as the type, the foot is simply suspended from the tibia by two double strands of silk; one double strand is quilted into the periosteum on the front of the tibia and then carried to the scaphoid, where it is sutured directly to the bone, while the other double strand passes from the same point to the cuboid.²¹ Nature encapsulates the strands of silk and thus the ligaments are formed. Insertion directly into the bone must be at one end only to allow for adaptation in growth. This method of fixation may be used early in treatment, before other measures are indicated, for the purpose of removing all strain from weakened muscles and so giving them a better chance to recover; later in the course of treatment it may be employed when no muscle available for transplantation is present and as a substitute for arthrodesis; it is also of frequent service as an aid to other procedures.

Skin Flaps.—A very useful operation for overcoming the tendency to deformity is the removal of skin flaps,²¹ which recommends itself on account of its simplicity. If the anterior muscles of the leg are weak, an oval piece of skin is removed from the top of the foot of such size that when the edges are approximated and accurately sutured the foot will be held in the desired position of dorsal flexion; by slightly varying the location of the flap to one or the other side the foot may be inclined toward pronation or supination. This procedure has the advantage of not interfering in any way with any subsequent operation: as a means of retaining the foot constantly in the desired position and obviating the objections incident to

brace treatment it is, therefore, applicable early in treatment and in very young children where other procedures are contraindicated. It may also be combined in other cases with tendon shortening and lengthening, and with transplantation or nerve anastomosis, as an aid in holding the part in an overcorrected position. Similarly, at the elbow the removal of a skin flap is of service in holding the joint in flexion, being in this region preferred by its originator to arthrodesis.

CONCLUSION

With all these measures for the improvement of function, orthopedic surgery of the present has much to offer the sufferers from this pitiable condition of infantile spinal paralysis, and it is rare indeed to find an untreated case in which some benefit cannot be given. Fortunately for us, treatment is most efficacious in the region most frequently affected—the foot. Yet in all regions enough can be gained to more than repay us for all our labor. To secure the maximum improvement a wise combination of the various procedures will usually be required.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. SILVER AND ROBERTSON AND CHESLEY

DR. ARCHIBALD CHURCH, Chicago: Every general practitioner must hail with delight the renewed activity of our surgical friends in the treatment of these very trying cases. My own experience is not very gratifying in the recommendations I have made for surgical operations in the correction of the deformities secondary to the inflammation of the cord of a poliomyelitic nature.

It has been the almost invariable result that after one or two operations either the patient, or his friends, or the surgeon becomes discouraged; and these operations have not been applied with sufficient frequency perhaps, to give the general operating surgeon much experience with, or much interest in them. The surgical fixation of a joint sometimes results very satisfactorily, especially in the knee or the ankle, yet I think astragalectomy unnecessary, because with very slight orthopedic apparatus the ankle-joint can usually be retained in a satisfactory position.

The recent recommendations of Dr. Schwab, carried out surgically by Dr. Allison, seem to promise something more satisfactory. They are not mutilating or destructive. By temporarily inhibiting the function by the injection of alcohol into the nerve supplying the muscles which have retained their function, and which tend to overact and so to produce the contracture deformities, one is enabled, according to the observations and experience of Allison and Schwab, to build up the power of the more or less atrophic, or completely paralyzed and atrophic muscles, and to secure better positions of the joints. This gives the opportunity for therapeutic massage and passive

and active movements; so that the patient is led to put into play that fraction of power which has been preserved and which under ordinary circumstances is entirely overmastered by the contracture tendency in the stronger group of muscles. The technic is particularly simple. A nerve supplying the given muscles is exposed and alcohol in various strengths, 50 to 90 per cent., is injected directly into them.

With the transplantation of muscles my experience has been decidedly unfortunate. The functional gain has been of minimal value; but if we can in many of these cases obtain the enthusiastic assistance of a manipulator or massage operator, who will devote himself every day for a number of years to necessary manipulations, apparently severe and hopeless cases will frequently present a degree of recovery almost marvelous. I recall the case of a young girl who suffered quite extensive involvement of the upper extremities, trunk and lower extremities. Yet in the hands of an empirical rubber who calls himself a doctor, who has devoted himself to this case for five or six years, this girl has recovered practically after a time when I supposed recovery was out of the question. She now has a fairly plump pair of lower extremities, walks readily and sits up without orthopedic assistance. Some of her friends do not even know that she has been afflicted with a grave disorder. I attribute the results to the physician's attention and the local manipulations of the muscles by massage. Of course orthopedic apparatus had been applied and modified from time to time; various splints and braces have been devised; but the absolute devotion of this man to this case has produced results which I wish we might parallel in others, and thus gives me the courage to say that under such treatment, perhaps with the assistance of the alcohol injections, we may look for better results than we have attained hitherto, and without the necessity of serious surgical intervention.

DR. L. H. METTLER, Chicago: I congratulate Drs. Robertson and Silver on their thoroughly scientific presentation of this subject. Dr. Robertson's paper indicates the beautifully logical way in which our knowledge has grown in regard to the nature of anterior poliomyelitis. We all remember how the disease used to be regarded as primarily an atrophic condition. In a word, the emphasis used to be laid on the wasting of the muscles and of the associated neurons. Then followed the suggestion that embolic and thrombotic obstructions in the terminal branches of the anterior spinal artery were probably the cause, with or without an accompanying inflammation, of the wasting of the anterior cornual cells. Now we have reached the point of recognizing the condition as a form of infective hemorrhagic myelitis, with the most destructive center of the inflammation located in the anterior horns. And finally we are beginning to suspect, on the strongest sort of grounds, that the infection is more or less specific in character.

It seems to me that this calls for a rewriting and reclassification of the disease in most of our text-books. Instead of referring to it as a systemic affection under the general impression that it is a unique and distinct trouble belonging to a particular functional tract of the cord, we should recognize it as merely a variety of myelitis. Abroad they are suggesting the advisability of dropping the "polio" from the name of the disease and calling it "focal myelitis." Whether we are prepared to make so radical a change in a name that has been so long in use may well be questioned. The use of the term "poliomyelitis" for general clinical purposes can do no very great harm if we are careful to keep always in mind that the disease is nothing but a form of infectious myelitis, with involvement, in some cases at certain stages of the process, of other parts of the cord beside the anterior horns, namely, the white matter and the meninges. The atrophic changes, and their disastrous results, which so dominate the clinical manifestations of the disease later on, are more or less secondary or subordinate phenomena in the sum total of its pathology. These atrophic manifestations (and I am speaking especially of the lower motor neurons whose cell bodies nest in the anterior horns) are in all probability analogous to the pyramidal degenerations that occur in the cerebral palsies of childhood. The essential pathology of the infantile cerebral and spinal palsies, especially when due to infective hemorrhagic

inflammation in the gray matter of the brain and cord, is in all likelihood the same and affords strong ground for the contention of Strümpell, more popular in Europe than in this country, that the differentiation of cerebral from spinal infantile palsy is a mere clinical differentiation dependent on the particular functional characteristics of the parts involved.

It seems to me very practical thus to lay the emphasis in infantile palsy on the infective hemorrhagic inflammation rather than on the later and subordinate degenerative processes. The former condition suggests some better hope of managing the disease than the latter conditions. Infections and vascular troubles are always somewhat more amenable to treatment than are progressive degenerations. An early diagnosis, therefore, is more imperatively demanded under the newer conception of the pathology of anterior poliomyelitis; and if the theory be ultimately confirmed that the disease is due to some special germ or toxin, all the more imperative will be the demand for an early etiologic diagnosis; for in the early recognition of the nature and cause of the disease will rest the highest hopes of preventing its spread and further progress both in the individual and in the community. And finally, if we succeed in discovering a serum or other means of overcoming the specific toxin in this form of myelitis, infantile spinal palsy—and perhaps likewise infantile cerebral palsy in some post-natal cases at least—will not be regarded so hopelessly as it has heretofore been under the old atrophic conceptions of the disease handed down to us by Charcot, who was able to study it pathologically only in the late stages. Much will be accomplished in the future in the prevention and treatment of these cases if the bright indications in the newer conception of their pathology and etiology continue to develop.

DR. P. BASSOR, Chicago: I am not surprised that Dr. Robertson finds no thrombosis in his cases, as that condition is exceptional. The question of meningeal involvement brings up the most interesting controversy that is now going on as to the mode in which the disease extends. Of course it is well recognized that in most of the fatal cases there is either an ascending or a descending infection. Most of the fatal cases present the picture of Landry's paralysis. According to Harbitz and Scheel there is a primary meningitis, very slight, with infection of the spinal fluid, and a secondary involvement of the cord along the vessels. Now, Wickmann of Sweden, who has examined about an equal number of patients, does not agree with this, although his findings are principally the same, but he interprets them in an entirely different manner. In all cases the extent of the inflammation is much greater in the cord than it is in the meninges, and it is greater in the central part of the cord, in the gray matter, and in the adjacent white matter, than at the periphery. So Wickmann says that inflammation occurs primarily in the gray matter of the cord. It is an infection with round-cell infiltration in the perivascular lymphatics, and it extends along the lymphatics up and down, so that the cause of the ascent or descent is not a successive involvement of different levels from the meninges, but an extension along the perivascular channels. Harbitz says that there are not enough lymphatic channels to account for that. The extension must be from the meninges. Now if in Dr. Robertson's cases there is a sufficient degree of meningeal infiltration to account for the extension, that would be of course in favor of Harbitz's theory; but if there are many cord segments in which the meningeal changes are minimal, it would be hard to account for the extension at all levels.

There seems to be no doubt that there are cases of this disease due to the same contagium in which we have only a meningitis; it is also true that there are cases of meningitis due to other organisms in which cord changes may be produced that are exactly like those in poliomyelitis. Attention has quite recently been called to that fact by Claude and Lejonne of Paris, and I have seen a man taken simultaneously with symptoms of meningitis and a flaccid paraplegia. That was three years ago, and I saw the man a week ago and he looked like a patient with an old case of poliomyelitis. If it had not been for the presence of the diplococcus found in the acute stage, I would say that it was an old case of poliomyelitis in which there had been considerable meningeal involvement.

DR. A. L. SKOOG, Kansas City, Mo.: I observed a number of cases last summer, while under appointment of the Kansas State Board of Health to investigate the Kansas epidemic of poliomyelitis acuta, both clinically and pathologically. One striking feature of the epidemic in Kansas was a grouping chiefly in bordering portions of two counties in the north-western part of the state. There were also isolated cases throughout different regions of the state. One of the noticeable points of this epidemic was the high mortality rate, about 33 per cent. of the patients dying. All told there were about forty cases in these two counties. Another interesting feature was the number of cases in adults. Adult cases have been reported, especially by Wickmann and others. Wickmann reports a patient aged 67. In this epidemic I was in consultation on one case, that of a woman aged 45, who also had marked cerebral symptoms. She died on the sixth or seventh day of the illness and I was unable to obtain permission to make an autopsy, but I did examine the cerebro-spinal fluid, which showed a lymphocytosis and a few polymorphonuclear cells, with a count of about 30 or 40 to the field of centrifuged sediment. The fluid was absolutely clear and contained no bacteria. No bacteria appeared on culture, on injection of guinea-pigs, rabbits, chickens and two rhesus monkeys. Another feature about this epidemic was the number of cases which puzzled the local physicians in making differential diagnoses from Landry's paralysis. In fact two physicians did diagnose Landry's paralysis; although from observation of this epidemic I believe Landry's paralysis may be considered as a form of poliomyelitis acuta.

In regard to lumbar puncture, it seems to me very important that we should obtain or look for some means of making an earlier diagnosis than we have in the past, and to me the examination of the cerebrospinal fluid has been attractive. I did a lumbar puncture in all the cases in which I could obtain consent, and that was about 7 cases out of 25. In all of them that I examined there was a mild increase in lymphocytes, ranging usually from 5 to 20 per centifuge or sedimented specimen. The fluid was absolutely clear in all the cases examined, and I could find no bacteria.

DR. ARTHUR S. HAMILTON, Minneapolis: The Section is to be congratulated on having the opportunity of listening to these two papers.

As Dr. Bassor has suggested, it has been shown that the cell changes found in poliomyelitis may be found also in other conditions in which there is an acute intoxication. In fact, as far as I know, it is quite impossible to tell the changes which occur in the large cells of the cord in one intoxication from those that occur in another. I have no doubt that in poliomyelitis most of the changes that occur in the cells are due to mechanical disturbance in the circulation, and the consequent upsetting of the nutritional balance of the cells; but I think we are safe in assuming that some of these changes are due to toxins, especially since the same changes can be found in other conditions where there is intoxication without mechanical disturbance in the circulation.

Six weeks ago there was admitted to the Minneapolis City Hospital a young man of 24, who passed through a very ordinary attack of lobar pneumonia, except that it was rather more severe than the average case. Aside from that there were no unusual features until, at the time when the man was about to sit up in a chair, it was discovered that he had no power in his legs. The physician had not observed it before, and the patient himself, though he had recognized the condition, had thought nothing about it, assuming that it was a natural consequence of his illness. When he came to get up he could not flex his thighs on the abdomen and had but slight power of flexion of the foot on the leg. There was no history of pain and, so far as I could make out, there was no disturbance of sensation. The patellar reflex and the Achilles jerk was absent. It did not look to me like a case of peripheral neuritis, although I find a few such cases have been reported as associated with pneumonia. There was very little subsequently of interest in the case and the man recovered quite rapidly. At the end of two weeks the reflexes had returned; he had obtained fair power in his legs; could stand without assistance, and in three weeks could walk out

of the hospital, and has since fully recovered. It seems to me that this is a case of poliomyelitis, not in a technical sense, but in the sense that the lesion is much more likely in the anterior horn cells than in the peripheral nerves.

In reference to the change of name of poliomyelitis, it does seem that the present term is rather misleading. At the same time I think we should hesitate to apply the term myelitis. It is true that the gross manifestation, as we see it, is a myelitis; but all the recent evidences show that we are dealing with a general intoxication, an infection of some sort. Dr. Robertson has brought that out in his statement of the post-mortem findings that there was evidence of acute intoxication in various other organs in addition to the changes which occurred in the cord. It seems to me, therefore, that we should wait for further light on the subject before we attempt another designation.

DR. NATHANIEL ALLISON, St. Louis: As orthopedic surgeons we are interested in these cases chiefly as the final results of a disease and we deal with final results, or hope to deal with them. The investigations recently made in the pathology of this disease makes it seem quite possible that in a few years there will be no more cases of poliomyelitis and no results of this disease to treat. This is a consummation much to be desired. Dr. Silver has gone over in a most systematic and complete way all the things that have been done surgically for the relief of poliomyelitis. He has taken the subject up in such a way as to leave very little to say about it, except in one particular, and that is the use of nerve anastomosis as a relief.

The selection of any operation for the relief of poliomyelitis must be based on a pretty wide experience and knowledge of the mechanical conditions to be brought about after the operation; many papers have appeared on this subject, and many reasons have been given for failure in tendon transplantation, for failure in arthrodesis, etc., and for failure following anastomosis. The work of Kilvington and other English experimenters shows that nerve anastomoses will regenerate and quite extensively. Dr. Schwab and myself have been working on these problems with the combined point of view of the neurologist and the orthopedic surgeon. We started to alcoholize the nerves in cases of poliomyelitis following the success we had in alcoholizing the nerves supplying muscle groups in spastic paraplegias and spastic quadriplegias. We have had some very successful cases in which there was overaction of the hamstrings, in which the alcoholization of the particular nerves supplying the overacting muscle group caused the overacting muscle group to cease to overact, and gave the weaker antagonistic group in spastic palsy a chance to pick up power.

Where there is sufficient power in a muscle or muscle group in the foot to produce a deformity, such for instance, as the deformity of club-foot, then there are active nervous elements in the leg. The question is to select these nerve elements and make what can be made out of them by nerve anastomosis, leaving the tendons and joints untouched. This should be considered always first as a procedure, because if regeneration is established the result will be better than that obtained by fixing a joint or by tendon or muscle transplantation.

We have done several operations of this nature, one for instance, in two cases of isolated quadriceps paralysis. The branch of the quadriceps was severed from the anterior crural trunk and put under the vessels into the obturator nerve. This has been followed by regeneration in both instances, and the opposing group to this return of power in this weakened quadriceps, is the hamstrings. The sciatic nerve was exposed down the back of the thigh and the branches to the hamstring muscles were injected with alcohol, thereby throwing out the opposing group for a more or less definite period of time.

The relative value of all the procedures properly performed has been clearly demonstrated in Dr. Silver's paper. Dr. Lovett has written a paper recently, in which he showed that failure was due to neglect on the surgeon's part of the after treatment of these cases. The patients are not cured when the operation is done. These are cases on which someone must put time, patience and much physical energy in order to secure the improvement that should be expected.

DR. FRANK R. FRY, St. Louis: We have all been hammering away at various modes of treatment for many years, and, as Dr. Church has intimated, with very little encouragement. In more recent times it seems to me the important function of the neurologist in these cases is to impress on the patient and those who have charge of them the fact that they have a chronic situation on hand for the treatment of which they must stir up as much enthusiasm among themselves as they possibly can in the midst of adverse circumstances. For instance, massage, I believe, is uniformly accepted by neurologists as the only rational routine method. We should tell our patients that massage must be practiced not for a few months but for several years. Many patients cannot afford to have the services of a professional rubber; we must educate somebody in connection with the case to carry on this work effectively.

Some years ago Dr. Hammond, of New York, taking a lot of old cases of poliomyelitis in which muscles showed no reactions whatever to electrical current, was able, continuing the current with persistency, to develop reactions in these muscles. He published this fact, but he never published the sequel of it, which I obtained in personal conversation with him, namely, that afterward these muscles lapsed to their former condition. That is the kind of discouragement to which we have become used. It is on account of that fact that neurologists to-day are more interested in what the orthopedists are doing, than in anything they feel capable of accomplishing themselves. I personally feel no comfort in trying to take care of a poliomyelitis patient without being in contact with a reliable orthopedist all the time.

DR. C. R. WOODSEN, St. Joseph, Mo.: I believe that the lack of success of orthopedic measures is due largely to the fact that too many men undertake to do this work, who are not familiar with the nervous system, especially its anatomy and the function of various nerves. There are few men who do this work well, and there should be a specializing along that line.

There is one thing that every physician who sees a case of poliomyelitis can do and should do, and that is, to make an early diagnosis. A lack of effort to diagnose is responsible in many instances for a failure to diagnose, but the important thing to do is to prevent deformities. It can be diagnosed before paralysis appears. It may not be diagnosed of course, until afterward, as has been stated, but the important thing is to retain a proper temperature and prevent deformity and institute early treatment of massage and electrotherapeutics. It is easy to prevent deformities if the case is taken early. In some cases treatment does not restore function, but the prevention of a deformity makes the cure much more easy.

DR. C. H. HUGHES, St. Louis: Having had a rather extensive experience in the direction of poliomyelitis anterior, as you may probably guess from the color of my hair, I wish to make an addition of something that has not been contributed to this subject.

Two instances are now in my mind of recoveries from poliomyelitis anterior. One child was brought to me in the arms of the nurse, sent to me by a very able physician down there in southern Illinois, where malaria is said by the inhabitants to be so thick that you could cut it with a knife. I noted that there were no cerebral symptoms connected with the case: this absence is to be expected in a typical case of poliomyelitis. There was no delirium; there had been no coma at any time; it was not a case of cerebral apoplexy: both lower limbs were paralyzed, and it occurred to me, being familiar with the practice of medical men in this section of the country and below, that I would add to my treatment a vigorous course of quinin. Quinin and protoiodid of mercury were sufficient to bring about a complete restoration in that case of poliomyelitis anterior within six weeks without deformity. I considered the cure complete in ten weeks and permitted the child to go home. That girl is now a grown woman, free from any evidence of any sort of the after-consequences, contracture deformities, etc., that so often confront us, to our dismay, in the management of poliomyelitis anterior. Unfortunately I have not had the good fortune in

the majority of my cases to see such satisfactory results effected.

In the other case the child was placed by the nurse on the steps on a hot summer day and fell asleep; and when the nurse came to it again the child had no use of its lower limbs, but had not lost consciousness, had no mental impairment, and no evidences of anything else except the involvement of the anterior horns of the spinal cord. That child recovered, and that is all the recoveries out of a good many cases that I might record.

Notwithstanding the microbic invasion in poliomyelitis acuta, we generally believe that its attack is somewhat similar to that of pneumonia. Now the common impression is that the chill permits the microbic invasion, and then we have the work done by the pneumococcus in pneumonia and the infective agent in this essential paralysis of children thus gets in its damaging work.

DR. H. E. ROBERTSON, Minneapolis: In regard to the involvement of the pia mater I am unable to agree with the authorities who urge that such involvement is primary. I have always found the involvement of the cord more marked in any particular region than that of the corresponding pia. The place of infection is the perivascular lymph-channels, extending to the interstitial portions of the gray matter of the cord, and second, to the lymph-channels in the pia mater, and even to the gray and white matter of the posterior columns.

DR. DAVID SILVER, Pittsburg: My paper was intended as a review of the literature of the present-day surgical treatment of this affection. Regarding Dr. Hammond's results, cited by Dr. Fry, one would naturally expect relapse, because, while muscular tissue was present, it was not sufficient to meet the demands of functional use. In such cases some procedure is obviously required to decrease the amount of work demanded of the muscles, as for example, arthrodesis.

An unusual amount of patience is required in dealing with these cases. I mentioned several procedures which seem to me of distinct value and I wish again to emphasize them. My first point is that in a drop-foot, for example, it is obviously of much greater value, early in the treatment, to fix the foot by taking out a skin flap or by making an artificial ligament, which does not interfere with any subsequent operation, than to fix it with a brace, because the brace not only interferes with the function of the part but its daily removal is a disadvantage: the part must be retained constantly in the position of maximum relaxation, if a return of power in the weakened muscles is to be secured. The second point is that in every case deformity must be overcome a long time before any operation for the restoration of function is attempted. Usually when the patient consults the surgeon, some operation like nerve anastomosis or tendon transplantation is at once proposed, instead of preliminary treatment being instituted to determine accurately the degree and the extent of the paralysis and to put the part in the most favorable condition for such operation. If such preliminary treatment is carefully carried out, I am sure our results will be very much more favorable.

BRONCHIAL ASTHMA AS A PHENOMENON OF ANAPHYLAXIS*

S. J. MELTZER, M.D., LL.D.
NEW YORK

It is now generally accepted that bronchial or idiopathic asthma is due primarily to a stenosis of the bronchioli. It is not necessary to dwell here on the particulars of this disease. For the purpose of this paper, however, the following facts may be mentioned. Asthmatic attacks occur only in individuals who are especially subject to it, that is in asthmatics. Furthermore, onset and disappearance of the attacks bear the

character of capriciousness. Heredity, also, seems to be an influential element in some instances. Finally, there is practically no pathologic anatomy in this disease. On the basis of these facts, bronchial asthma is considered as a functional disease which, according to the prevailing view, means a neurosis; hence also the term nervous asthma. From the symptomatology we shall mention here only the following points: By percussion it can be established that during an attack of asthma the lungs are overdistended. The auscultation reveals that there is a considerable decrease of the respiratory exchange of air despite the greatly increased efforts of the respiratory muscles.

There are two theories regarding the nature of the nervous origin of the bronchostenosis in asthma. One theory assumes that the stenosis is due to a vasomotor disturbance, which brings about a swelling of the mucous membranes or of the submucous tissues of the bronchioli, causing thereby a narrowing of their lumen. The other theory assumes that the stenosis is due to a tonic contraction of the muscle fibers surrounding the finest bronchial tubes. At present, the latter theory is accepted by most of the clinical writers, especially since it was established by the careful physiologic investigations of Einthoven¹ and of Brodie and Dixon,² that by stimulation of the peripheral end of the pneumogastric nerves a stenosis of the bronchi takes place which is due exclusively to a contraction of the muscle fibers and not to the production of circulatory changes of any kind. According to this theory an attack is brought on by a stimulation of the broncho-constrictor nerve fibers which run in the pneumogastric nerves. It is assumed that the stimulation takes place, in some obscure way, mostly in the medulla oblongata; in some cases, however, it may be brought about in a reflex way from some peripheral organ. At any rate, asthma, according to this view, is a nervous affection and has its origin in the central nervous system.

It is my intention to attempt to interpret the asthmatic paroxysm as a phenomenon of anaphylaxis, assuming at the same time that the process is a peripheral one. This attempt is based on some very interesting facts recently discovered by Drs. Auer and Lewis³ in the Department of Physiology and Pharmacology of the Rockefeller Institute. In order to understand clearly the points I wish to bring forward, permit me to make a few elementary remarks on the subject of anaphylaxis or hyper-susceptibility.

ANAPHYLAXIS

Anaphylaxis is in an essential point the reverse of immunity. All know what immunity means. Every physician is familiar with the fact that a patient who has recovered from an infectious disease, typhoid, for instance, is less susceptible to a second infection from the same disease. The same applies to the effects of toxins. The experimental work of the last two decades has furnished ample evidence that the injections into an animal of non-fatal doses of toxins, for instance the toxins of diphtheria or tetanus, make this animal more resistant—it immunizes it—against this very toxin. In other words, the passing through a definite infection or intoxication is the means of a decrease of the susceptibility of that animal to the specific infection or intoxication. There were, however, scattered facts which indicated also that the reverse of immunization may occur; that is, that instead of a decrease of susceptibility, an increase may

occur. For instance, the passing through an attack of erysipelas seems to prepare the individual for recurrent attacks of this disease. The same is perhaps also true of pneumonia. In the extensive work on the immunization against toxins, several investigators recorded observations to the effect that an immunization led up to a hypersusceptibility.⁴ However, about five years ago, striking experiments became known which all at once raised this issue to a problem of considerable importance. Our president told us that the present annual meeting is the twenty-fifth of our Society, and pointed with pride to the good work which the members have contributed to medical science. Permit me therefore the historical remark that the striking and fundamental facts on which the very interesting chapter of anaphylaxis rests were first observed and developed by members of our Association. In the course of his studies of the effects of diphtheria toxin and antitoxin on guinea pigs, Theobald Smith observed (1903) that by repeated injections of toxins, these animals instead of becoming immunized sometimes manifested rather a definite increase of their susceptibility to the poisonous effects of the diphtheria toxin. These observations Dr. Smith communicated orally to Paul Ehrlich during his sojourn in this country. On his return to his Institute in Germany, Ehrlich caused one of his pupils, Otto, to investigate systematically this observation, who, in publishing his results, designated the fact of the hypersusceptibility as Theobald Smith's phenomenon. Simultaneously, and independently of any other observer, the striking phenomenon was observed and extensively investigated by Dr. Rosenau in conjunction with Anderson.⁵

EXPERIMENT

The fundamental experiment which brings out this phenomenon in a striking manner is as follows:

A guinea-pig receives a subcutaneous or intraperitoneal injection, let us say, of a small dose of horse serum. The injection produces apparently no effect; the animal remains perfectly normal. When, however, a few weeks later a second injection of horse serum is given to this animal, let us say one c.c. of the serum, given intravenously, the animal dies within a few minutes with striking manifestations. This is an absolutely reliable experiment which never fails. Now you observe that the result as described here was accomplished not with a bacterial secretion, a diphtheria or tetanus toxin, or an endotoxin of any other bacteria, but simply with normal horse serum, which seems to be innocuous in its first injection. In fact, this hypersusceptibility can be produced with such harmless proteins as egg albumin, milk or some vegetable protein, edestin, for instance.⁶ A striking feature of this phenomenon is that it is strictly specific; if the first injection was made with horse serum, the phenomenon will occur only when horse serum is used in the second injection, or if edestin was used in the first injection, only a second injection of edestin is capable of producing the fatal phenomenon.

Let me now say a word about the origin of the term anaphylaxis. It was created by Richet some eight years ago. In studying the effects of a poison which he isolated from actinia he distinguished two opposite actions one which produces prophylaxis (immunity) and another which produces anaphylaxis (hypersusceptibility). The term anaphylaxis found general acceptance.

Now let us remember first of all that for the production of anaphylaxis two stages, two separate processes are necessary. The first part consists simply in an injection into the animal body of some foreign proteid. It produces practically no visible effect, but it sensitizes the organism; we call it therefore the sensitizing injection. It need not be an intravenous injection; an incorporation of the proteid in any other manner will have the same effect. The quantity of the proteid is also of no special importance; a very minute dose of the proteid sensitizes an animal. The second part consists, as stated before, in a repeated injection of the same proteid; this is the toxic injection. The effect of this injection is, indeed, most striking, especially when it is given intravenously. The quantity is also of some importance; the larger the dose, the more prompt is the effect. The second injection should not be given too soon after the sensitizing injection; the interval between the two injections should be at least twelve or fourteen days.

The sensitizing effect may be transmitted from the mother to the offspring which, however, may gradually dwindle away. The acquired sensitization leaves a long-lasting impression; even after years a second injection is capable of producing a definite toxic effect. The effect, however, is not always fatal and as striking as described above. When the second dose is not sufficiently large, or when administered in a less effective manner, the guinea-pigs may recover from the "anaphylactic shock" (as the violent attack is often designated), or the attack may set in with less violence.

PHENOMENA OF ANAPHYLACTIC SHOCK

We now come to a discussion of the point which interests us here mostly, namely the character of the attack. From the start, all observers agreed that the death of a guinea-pig in an anaphylactic attack is due to respiratory failure. The attack consists in exaggerated respiratory efforts and manifestations of profound dyspnea. Most of the writers assumed that the cause of this fatal respiratory disorder is located within the respiratory center in the medulla oblongata. Gay and Southard,⁷ who have done meritorious work on the problem of anaphylaxis, are emphatic in their claim that the fatal respiratory phenomenon is due to a hyperstimulation of the respiratory center. Although Gay and Southard noticed that the lungs of guinea-pigs dying in anaphylactic shock are "emphysematous" they considered this condition as being only a secondary effect of the violent inspiratory contractions of the diaphragm, the primary cause of the attack being, as stated before, the over-stimulation of the respiratory center.

The recent investigations of Auer and Lewis, however, have in my opinion definitely established the true cause of the anaphylactic shock in guinea-pigs. In the first place, they have established that the lungs, which become greatly distended with the onset of the attack, remain in a distended state even after their complete removal from the thoracic cavity after the death of the animal; in fact, the lungs do not collapse even when cut into pieces. An anatomic study of the lungs demonstrated that the distention is due neither to emphysema nor to pulmonary edema. Furthermore, the typical condition of the lungs remained the same even if the second, toxic injection of the serum was administered while the animal was under the influence of curare (and the life kept up by artificial respiration); that shows that the

4. We may mention here: Behring (1893), Richet (1902), Arthus (1903), Wolf (Elsner), (1904) v. Pirquet and Schick (1905).

5. The publications of Otto as well as those of Rosenau and Anderson appeared in 1906, and I am at present unable to state which one of the publications was ahead of the other. But I can bear witness to the complete independence of the observations of Rosenau and Anderson, because in December, 1905, Dr. Rosenau was kind enough to communicate to me their remarkable experience, and we discussed the possible meaning of the phenomenon.

6. First successfully employed by P. A. Lewis.

7. Gay and Southard: Jour. Med. Research, 1908, xix, 22.

distended state of the lungs cannot be simply a secondary effect of the violent contractions of the diaphragm. The real character of the dyspnea was revealed by the fact that during the anaphylactic attack the lungs could not be further inflated by artificial respiration; that is, air could not pass through the bronchi into the alveoli while the respiratory efforts produced at the same time a strong negative pressure in the pleural cavities. Finally, Auer and Lewis have established that the anaphylactic attack takes place in animals with a destroyed central nervous system, exactly in the same way as in normal animals, which proves that the process is of peripheral origin. In other words, Auer and Lewis have definitely proved that the cause of the acute anaphylactic death of guinea-pigs is a stenosis of the bronchi due to a peripheral process. This process consists, Auer and Lewis believe, in a constriction of the bronchi due to a tonic contraction of their muscle fibers. It is sure that these contractions are not brought about by central impulses. Whether these contractions are brought about by a stimulation of the muscle fibers themselves or of the nerve endings, this question Auer and Lewis have not attempted to decide for the present. They have discovered the important fact that in many cases the anaphylactic attack can be prevented by a previous injection of atropin. This fact would indicate, according to the accepted view, that the nerve endings are responsible for the attack. On the other hand, Auer⁸ recently found that the attack would set in even in animals in which the vagus nerves were cut a long time before the second injection. The nerve-endings therefore must have been degenerated previous to the anaphylactic attack. We may add here that the important results of Auer and Lewis were confirmed by Anderson and Schultz⁹ and by Biedl and Kraus.¹⁰

SIMILARITY TO NERVOUS ASTHMA

The following facts, observed by Auer and Lewis, are of special interest to us here. In an anaphylactic attack the bronchi are constricted: no air can pass into the alveoli, nor can it escape from them; and the lungs are greatly distended and cannot collapse. It was shown that the constriction of the bronchi is of peripheral and not of central origin. Now exactly similar symptoms are met with in so-called nervous asthma. During the attack the bronchi are constricted, air passes through them only with great difficulty. Is asthma a nervous process and of central origin, as is generally assumed, or is it an anaphylactic phenomenon and essentially of peripheral origin? That is, may we not assume that asthmatics are individuals who are sensitized to a definite proteid substance and that the asthmatic attack takes place when the same proteid substance invades the body in the same manner? For one form of asthma this has been established experimentally, and that is for hay fever asthma. As is now well-known, hay-fever is due to the toxalbumins of the pollen of some plants. When such a toxin is injected subcutaneously into a normal individual, it causes no effect whatsoever. If, however, a minute quantity of it is injected into an individual who is subject to hay-fever, in a short time all the symptoms of hay-fever appear, and among them a definite attack of asthma. This can mean only that hay-fever subjects are sensitized to a specific proteid of the pollen of a definite plant, and that whenever the same proteid

invades these individuals in some way or other the result is an anaphylactic attack, which, among other phenomena manifests itself in the form of asthma. May we not explain all other forms of asthma in the same manner?

According to this view, to repeat again, an asthmatic is an individual who is sensitized to a definite substance and an asthmatic attack sets in every time this substance manages in some way to enter into the circulation of that individual. We must bear in mind that even in the crude manner of our experiments a very minute quantity of the specific proteid is sufficient for the sensitization as well as for the intoxication. In the actual processes which take place in Nature the effective doses may be infinitely small, and it may well be possible that the minute quantities contained in the emanations from horses, cats or guinea-pigs are sufficient to act as a toxic dose and call forth the non-fatal stenosis of the bronchi evidently present in an asthmatic attack in the human. Perhaps certain digestion products of the proteins become now and then absorbed into the circulation from the alimentary canal in some cases in an abnormal stage.

Such an absorption may have little or no influence on normal individuals, but will call forth an anaphylactic attack, that is, an attack of asthma, in an individual sensitized to this protein product. We need not attempt to work out the details of our theory. Our knowledge of the anaphylactic process is yet too young and too scanty for such an undertaking; any application in detail will surely soon have to be rearranged. But with our theory in mind, a future study of cases of asthma might bring to light definite causal relations, just as happened in the studies of hay-fever. For the present, the following parallel facts may be recalled to mind. The sensitization to anaphylaxis may be hereditary or acquired; so is the disposition to asthma either hereditary or acquired. Anaphylaxis is specific; animals sensitized to a definite proteid can be intoxicated only by that proteid. The same seems to be true also for asthma. This is certainly true for the hay-fever asthma. Individuals who suffer from hay-fever in the spring due to the grass pollen are not subject to the autumnal attacks which are caused by the ragweed pollen. But the specificity seems to hold good also for other cases of asthma. For instance, individuals who get attacks of asthma in the presence of cats do not get it by the emanations from horses or from guinea-pigs. A most interesting and valuable point is the fact that atropin, which relieves asthma, relieves, as it was discovered by Auer and Lewis, also the anaphylactic attack. On the basis of the identification of the two phenomena there is an encouraging outlook for the therapeutics of anaphylaxis as well as for asthma. But I shall not indulge in a further discussion of the details of our subject.

SUMMARY

It is generally agreed that the so-called nervous asthma is due to a stenosis of the bronchioli. It was discovered that the so-called anaphylactic shock is due also to a stenosis of the fine bronchi. The theory is here offered that asthma is an anaphylactic phenomenon; that is, that asthmatics are individuals who are "sensitized" to a specific substance and the attack of asthma sets in whenever they are "intoxicated" by that substance.

It has been proved that the anaphylactic attack is of peripheral and not of central origin. It is therefore suggested that the so-called nervous asthma is also due to a

peripheral and not a central cause; in other words, "nervous" asthma is not a neurosis.

On account of the capriciousness of the onset and courses of asthmatic attacks, as well as on account of the absence of pathological-anatomical changes in this affection, asthma was considered a functional disease and hence a neurosis. From our point of view asthma is still a functional disease but not a neurosis. We have therefore a significant instance in which a functional disease need not be of nervous origin.

VOMITING OF GALL-STONE

J. M. PFEIFFENBERGER, M.D.

ALTON, ILL.

The following is herewith reported to place on record a case which I believe is rare enough to be of some interest:

History.—Mrs. S., aged 40, was seen on July 3, 1910, at which time she complained of nausea and "feelings of distress" in the epigastric region. There was no rise in pulse-rate or temperature. Palpation over gastric and hepatic region elicited no tenderness. The patient had been constipated for several days and gave a history of three attacks of similar nature while traveling in the west, one on April 7, another April 15 and the third about May 1, the attack on May 1 being diagnosed as appendicitis. She was given one grain of mild mercurous chlorid every hour for three doses, the evening of July 3. Early the next morning, July 4, the nausea became very distressing and the patient vomited about 6 to 8 ounces of mucus and gastric juice, after which she took a glass of champagne to relieve the distress. About twenty minutes after taking the champagne she vomited (in my presence) a drachm or more of what looked to be pure bile and a small dark substance which made an audible click when it struck the side of the vessel. On closer examination of the substance it was found to be a gall-stone of the cholesterol and bilirubin-calcium variety, with two facets on it. Following the expulsion of the stone and bile the patient seemed to obtain immediate relief and did not vomit again. On deep palpation I could now find some tenderness over the gall-bladder area.

Dr. O. H. Elbrecht of St. Louis saw the case in the evening with me.

Operation.—July 6, the gall-bladder was exposed through a right rectus incision and found irregular in shape, of normal size, with walls in a healthy condition and no adhesions present. The appendix was looked at and found to be held down with a few adhesions which were separated and the organ removed by the usual method of crushing and invaginating the stump with purse-string suture. The area around the gall-bladder was walled off with gauze and the organ incised at the fundus, allowing the escape of a small quantity of bile and seven medium-sized stones, ranging in size from a grain of wheat to a hazel-nut, then one large stone the size of a large Brazil-nut was removed with a spoon curette, the gall-bladder thoroughly sponged out and the cystic, common, and hepatic ducts palpated but no stones felt. The packing was next removed and the gall-bladder drained with a rubber tube placed in the fundus and fixed by a purse-string suture to the parietal peritoneum, the wound closed by tier suture, and the patient dressed and placed in bed.

Postoperative History.—The patient was nauseated for some time afterward and next morning vomited a large quantity of bile, and passed a quantity by tube. The tube was removed on the fourth day; the stool was bile-stained on the

seventh day. There was no rise of temperature or pulse following the operation. The patient was removed to her home on twelfth day and her bowels moved of own accord on fourteenth day. The wound was entirely healed on the fifteenth day. A very interesting and extremely satisfactory result to the patient, who had been dependent on cathartics and enemas for the last eighteen years, is that since two weeks following the operation her bowels have been moving daily and sometimes twice daily without assistance.

I am preparing a paper on the records of all cases reported of vomited gall-stones and I should be pleased to hear from physicians who have had such cases to report.

Special Article

EPIDEMIC POLIOMYELITIS.

A DISCUSSION OF THE PREVALENT INFANTILE PARALYSIS

Epidemic poliomyelitis has long been known under the name of infantile paralysis and under this name its symptomatology has been described in the text-books. Small outbreaks have been described, one occurring in the United States as early as 1841, but epidemics were not frequently noticed until about 15 years ago. The prevalence of the disease appears to have been increasing since that time. An extensive outbreak occurred in Sweden in 1905 and two have occurred in Australia, one in 1903 and the other in 1908. An extensive epidemic occurred last year in Prussia, especially in Westphalia. The principal epidemics in this country during the last 3 years have occurred in Boston, New York, Minnesota, Kansas, etc., and the disease has been unusually prevalent during the past summer in many states.

The interest excited by these epidemics has led to a great deal of investigation which has advanced our knowledge of the nature of the disease.

The disease is a general infection, attacking chiefly the nervous system and localizing itself in the anterior horns of the spinal cord.

ETIOLOGY

July, August, September and October are the months in which most cases occur. Both sporadic cases and those in epidemics have been noted to occur after hot dry weather. The disease is more prevalent in cold than in warm countries. Clinical experience has shown that the disease is contagious, though it is perhaps not highly so. The way in which it is communicated is not certainly known. Dust has been suggested as one means of conveying the contagium. In the Massachusetts epidemic out of 150 cases investigated 62, or nearly half, had been swimming or wading in water contaminated by sewage, just before the onset of the disease. The experiments of Flexner give some reason to believe that the virus is contained in the mucous membrane of the pharynx to an unusual degree. On the other hand, careful autopsies have shown that lesions of the tonsils or of the pharyngeal mucosa are not constant.

The nature of the virus is not known. That it is a living organism is rendered probable by the fact that it can be transmitted from man to the ape and from this ape to a second ape, as shown by experiments of Flexner and Lewi-

and Römer. The disease was first communicated to apes by intradural injection of the substance of the spinal cord. Subsequent experiments of Flexner have shown that the same results can be obtained by intraperitoneal and even by subcutaneous injection of the filterable virus. The germ, if such there be, is so small as to pass through a Berkefeld filter. No micro-organism has been discovered that can be regarded as the cause of the disease.

PATHOLOGY

The pathologic changes are thus summed up by Hochhaus: There is a vascular inflammation of the anterior horns (gray matter) throughout the whole axis of the spinal cord; in addition the inflammation often extends to the posterior cornua, the white substance and to the meninges. In many cases the medulla and the pons are affected as also the brain. This appears to be constantly the case in the severe cases.

SYMPTOMATOLOGY AND COURSE

The disease varies as to degree of severity, type and structures most prominently involved, and for convenience in description may be divided into the following forms: The abortive form, those of moderate severity, the acute ascending poliomyelitis of severe type, the bulbar and the encephalic. Abortive cases may not be recognized by one not familiar with the condition even during epidemics. The incubation period is from five to thirty-three days, the average being about ten days in the experimental cases of Flexner and Lewis. Beneke found in some experiments on rabbits that the animals showed no symptoms for from eight to eleven days. The first symptoms usually observed in all forms are connected with the gastro-intestinal tract; in 90 per cent. of cases as found by Krause. In two-thirds of these there was diarrhea and in the remainder constipation. Rarely the disease begins with angina or with inflammation in the respiratory tract. In the mild or abortive cases there may be a moderate degree of fever, sweating, some headache, the patient is restless and complains of neckache and backache, with pains down the legs, and in young infants there may be muscular twitchings and sensitiveness when handled. Leucopenia is an important initial symptom, as noted by E. Müller. In many cases the child cries with the slightest movement. Delirium rarely occurs. The sensorium is usually unaffected. Symptoms occurring during the course of the fever, at first interpreted as weakness, may be the signs of the beginning paralysis, and should be watched for. The child may not be able to sit up or hold up its head. According to some authors, there is no forcible retraction of the head, but a falling backward of the head from paretic relaxation of the muscles. The symptoms subside in a few days and then it may be noted for the first time that the patient is disinclined to use the legs, or complains of muscular weakness and fatigue to a greater extent than would be warranted by the length of the illness, but no actual paralysis develops and recovery is complete in a week or two.

In the moderately severe form the symptoms are similar, but more severe. There may be rigidity of the neck and retraction of the head, the temperature is higher, running up to 101 to 103 F., with vomiting, sweating, prostration, restlessness and severe pains in the back and extremities, and in some cases with inability to empty

the bladder or to control the bowels. In three or four days a flaccid paralysis occurs involving a group of muscles, one extremity, or both, or may involve the trunk or upper extremities. This paralysis reaches its maximum in a few hours, or perhaps in three or four days, and in a week or ten days begins to improve, which improvement continues until only a small amount of paralysis remains, but this is usually permanent. Recovery may, however, be complete even in severe cases during epidemics. The ganglion cells controlling many muscles do not degenerate. These recover in a short time, while the muscles corresponding to permanent lesions in the spinal cord remain permanently paralyzed. This permanent paralysis usually affects the legs; rarely the arms. Paralysis of the thighs is uncommon, and usually only a group of the leg muscles is permanently affected. Anesthesia has been observed.

The acute ascending type is like that last described, but the lower extremities, bladder, rectum, abdomen, diaphragm, back, chest, upper extremities, throat, etc., are involved in succession until the paralysis reaches the medulla when respiratory paralysis and death ensue.

In the bulbar form, aside from the other general symptoms, the paralysis first attacks the bulbar region, causing paralysis of the throat, eyes, face, tongue, with strabismus in various forms, difficulty in deglutition and phonation, choking and other related symptoms. Respiratory paralysis may also occur in this form as in the ascending type. Recovery may be complete or partial.

In the severer forms in which death does not occur there may be a period in which the patient remains in about the same condition and then improvement in the paralysis occurs rapidly to a certain point, and then slowly for a period of about two years, after which any remaining paralysis is permanent.

IMMUNITY

Flexner and Lewis have found in their experiments that one attack probably confers immunity from subsequent attacks. They have also established immunity by repeated injections of the filterable virus in gradually increased quantities.

DIAGNOSIS

The prospect of efficient treatment of this disease depends on early diagnosis. No treatment can accomplish much after paralysis has supervened. It is during the period of fever and initial paralysis that an antitoxin or immune serum if one were available would need to be applied in order to do any good. It is therefore of the utmost importance that the earliest symptoms of illness—especially in children during the prevalence of poliomyelitis—should be closely scrutinized with a view to discovering diagnostic points that may make the early recognition of the disease possible. At present little positive aid can be obtained from our knowledge of the symptomatology. It must be differentiated from cerebrospinal meningitis. In the latter disease the cerebral symptoms are more pronounced, the retraction of the head and stiffness of the spine more characteristic, and there is absence of paralysis. Examination of the cerebrospinal fluid would also help to differentiate the two conditions. The conjunction of diarrhea, fever, and sweating is suggestive and should afford reason for investigating the case carefully. Such a patient, especially a child, should

be visited at frequent intervals and examined for the first symptoms of paralysis. The examination of the blood will show leucopenia. Some observers have found an increase of lymphocytes in the cerebrospinal fluid. The occurrence of the general paralysis manifesting itself in the form of weakness, together with pain in the limbs and tenderness on moving the spine, is confirmatory. The predominance of a flaccid paralysis in one or more groups of muscles in the lower extremity completes the diagnosis.

PROGNOSIS

The mortality has varied considerably: in various epidemics from 5 to 20 per cent., in some cases being as high as 40 per cent. It is usually not very great. Evidence of abortive cases is afforded by the fact that in many instances other members of the family have suffered from diarrhea without the paralytic symptoms (Krause). There are probably also cases in which death occurs, sometimes suddenly, from the general infection without any symptoms of paralysis. Beneke noted such results in two of the rabbits inoculated by him. The possibility of complete recovery from the paralysis is admitted, but Krause met only one such case in the Westphal epidemic. In the Boston epidemic 10 per cent. of 628 patients recovered completely. In a smaller group of 150 patients who were carefully examined 25 or 16.7 per cent. recovered completely (R. W. Lovett). The prospect of improvement in the paralyzed limbs is good, although regeneration of the destroyed ganglion cells is not to be hoped for. The causes of death are the toxemia, cerebral complications, such as meningitis, and respiratory paralysis.

TREATMENT

As no specific is known, treatment must be symptomatic. Treatment suitable to an infection and toxemia should be promptly instituted. The bowels should be emptied by calomel and a saline and by colonic flushing, whether diarrhea or constipation be present. Elimination by the kidneys should be stimulated by a suitable alkaline diuretic, such as liquor potassii citratis. Salicylates may be given both for the relief of the pain and as being antagonistic in a general way to infections. The patient should be confined to bed and kept warm and comfortable. In view of the marked tenderness, Hohmann has recommended the application of a plaster cast. Gowers recommends that the patient be not permitted to lie on the back on account of the danger of increasing the congestion in the spinal cord. If a position on one or the other side is impracticable, pillows against the back will raise the spine from the lowest position and save the inevitable hyperemia from being augmented by the effect of gravitation. Strychnin should not be given until after the first two or three weeks. Electricity should be deferred a little longer. Gentle massage may be commenced sooner by upward rubbing with such pressure as causes no pain. Kneading of the muscles is better avoided. Re-education of the muscles by encouraging the child to use the paralyzed limbs should be begun after the acute symptoms have subsided. In this way other groups of muscles may be made to perform more or less perfectly the functions of those permanently paralyzed.

Therapeutics

CHRONIC ARTHRITIS

Whether one or more joints are in chronic trouble, or whether the disease is more general as in arthritis deformans, or whether the trouble with the joints is due to gout, chronic arthritis is one of the most troublesome, unsatisfactory, and discouraging conditions to treat. Anything that will cause a better understanding of the etiology of the condition will not only lead to its prevention before actual lesions of the joints have occurred, but will often aid in producing a cure or stay of the disease if the etiologic factor can be removed.

Dr. Hermann W. Marshall (*Johns Hopkins Hospital Bulletin*, July 1910) discusses this troublesome subject, and reminds us "that joint symptoms occur in constitutional infections and nervous diseases, and that their causes are manifold, and moreover the various etiologic elements do not act on a simple tissue, but on a complex structure including bone, cartilage, connective tissue, nerves, synovial membranes, blood capillaries, and lymphatics." As a result the bone may atrophy or hypertrophy, cartilage may be destroyed, there may be thickening of the fibrous tissue, there may be localized edemas or actual effusion into the joints, there is always stiffening and pain, and there may be ankylosis.

Marshall emphasizes the importance of the character of the blood, as it by bringing irritants to the joints, becomes an important factor in the cause of joint disturbances. Besides these chemical irritants, disturbances in the nervous system can reflexly affect joints, and the joints may be disturbed by physical conditions, pressure, sprains, etc. In any particular instance any one of these three factors may act in varying degree, and also Marshall believes that one or more joints may have their vital resistance reduced so as to be susceptible to what another joint may withstand.

Irritating substances in the blood that may injure joints are "chemical products of bacterial growth, chemical products derived from the gastro-intestinal tract, metabolic products of organ activities, and drugs such as lead." Bacteria may locally infect a joint and produce substances that are irritant. Ptoains circulating in the blood may irritate joints as seems proved by the fact that eradication of ptoain infection from the gastro-intestinal tract and a modification of the diet to prevent further ptoain poisoning or ptoain production has immediately relieved joint pains. While we cannot exactly define or chemically describe a toxin, Marshall states that these are formed by the action of bacteria on nitrogenous food materials, and certainly it has been shown that the removal of all such toxins from the system has many times entirely removed and prevented joint pains. In other words, there seems to be no question that irritants (whether the actual chemical substance produced by bacteria, or whether toxins from bacterial activity, or ptoains absorbed from the intestines) can cause joint pains often general, perhaps localized in joints that are physically disabled, and have their withstand power temporarily reduced. The removal of such intestinal malproducts cures the joint pains.

Marshall believes that the products absorbed from bacterial action in the colon, and from the stomach and intestines under pathologic conditions without bacteria, are causes of joint irritations. Certainly clinically, as he states, many a chronic arthritis patient gives no antecedent except chronic indigestion. Visceral displace-

ments causing indigestion without any apparent bacterial infection have been accompanied by joint disturbances and the joint disturbances have become better when the displacements were corrected. Marshall states that when chronic indigestion seems to be an etiologic factor in joint inflammations generally the bone hypertrophies, which seems to indicate a different kind of irritant from that produced by bacterial toxins which lead to destructive atrophic bone changes.

Hyperactivities or disturbed activities of the organs or glands of the body seem to frequently be the cause of joint irritations. This is sometimes noted after pregnancy, in thyroid disturbances, and pancreatic disturbances. It is certainly true that the beginning of gouty joints and sometimes of arthritis deformans dates from the cessation of ovarian activity.

When disturbances of the nervous system affect the joints, as Marshall well says, it can hardly be a simple proposition. If an individual nerve to a particular joint or set of joints is in trouble it can readily be understood how tropic changes in the joints take place; or if a particular portion of the spinal cord is affected how the joints that are enervated by that portion may become so disturbed as to show signs of irritation and inflammation. In general nervous conditions, however, the organs concerned in digestion are greatly disturbed, intestinal indigestion occurs and the absorption of irritants may take place, and these irritants may be the cause of joint disturbances in many nervous diseases.

Mechanical injury to the joints whether irritation, pressure, over-work, or insufficient circulation from some old injury, or anything that disturbs the nutrition of a particular joint or set of joints may become causes of chronic arthritis.

A thorough investigation of an individual patient who has chronic arthritis, with all of these etiologic suggestions in mind, will discover the best possible treatment and the treatment that promises most for the individual. It certainly is useless to direct a local treatment or even a general treatment without first endeavoring to remove the etiologic factor, if such a factor can be removed. If the diseased joints incapacitate a patient for work or exercise, compelling him to live a sedentary life, mal-digestions are bound to take place, and irritants in the blood will be ever present, if not actually on the increase, and the arthritis must progress. Prevention, then, of gastro-intestinal indigestion and the regulation of the diet in such a way as to assure the least possible absorption of toxins or chemical irritants is of primary importance. Although not mentioned by Marshall, it seems very necessary to study, by examinations of the feces and examination of the twenty-four hours' urine, the ability of the patient to digest the different kinds of food and properly to excrete the various salts, and to limit his diet to those which he properly cares for and to remove a food or salt, or diminish it at least, that he did not normally digest, metabolize or excrete. The amount of water a patient should drink seems to be another important factor in aiding the cure or prevention of progress of the joint affection. A blood count is also necessary. Many patients are anemic; many not. Many such patients have disturbances of the white blood corpuscles which should be noted. Worry, nervous frets, and all excitement that tends to neurotic conditions should be prevented, if possible. Here is one of the greatest values of temporarily removing a patient who has a number of joints affected, showing that there is a general cause for the trouble, to a private hospital or

sanatorium for treatment. Serious nervous affections give, of course, a serious prognosis to the joints affected.

Various measures for producing local hyperemia are valuable. If the disease is more or less general nothing is any more valuable than body baking, the so-called hot air treatment. It increases elimination through the skin, promotes the circulation of the surface of the body, relieves pain, and increases the activity of the circulation in the joints. It also relieves the congestion of the internal organs and therefore is an aid to digestion. If the general circulation is poor the baking should be done under careful supervision, to promote the circulation, and not to have the baking so frequent or so prolonged as to debilitate the patient. If properly managed this baking is of the greatest aid in helping these patients. If the disease is localized in one or more joints repeated local baking may be valuable, but often does no good, and may do harm. If there is no improvement after a certain length of time certainly the treatment should be discontinued.

The production of localized hyperemia in certain joints by bandaging, the Bier's treatment, may be of value, but often in chronic conditions it is of no value. Active massage and passive movements may be of great value. Various electric stimulations to the spine may be of value in individual patients, but often probably do more good psychically than physically. Electric light bath treatments and various hydrotherapeutic measures all have their value and all do good. Whether a joint should be immobilized or not is a question for careful decision. If there is acute inflammation it should probably be temporarily immobilized. Sometimes such immobilization will almost produce a cure, and again a joint becomes stiff and is really injured. Such fixation treatments, then, should be carefully considered before they are inaugurated.

Medicinal treatment, except such treatment as is aimed to promote digestion, proper bowel activity, proper circulation, and proper character of the blood, is of little value. If there is thought to be hyperacidity of the secretions or at least decreased alkalinity, alkalies may be of value, but certainly alkalies should not be pushed to the point of interfering with stomach digestion. Salicylates are of but little value in chronic joint disturbances. Iodids in large doses will produce waste, and may be what a fat patient needs. Small doses of iodid stimulate the thyroid to extra activity, promote general metabolism, and may be of value in the individual case. Colchicum in chronic arthritis is probably of little value except as it may increase intestinal activity. All of the various lithia salts, and all of the various laxative and alkaline waters have no specific action, but if combined with increased muscular activity, increased activity of the skin, increased drinking of water in proper selected cases, a regulated diet and a regulated life, in other words, proper regime, they may be of apparent benefit. It is the regime, however, and not the particular kind of lithium or other salt that works the cure.

Let it be urged that a physician cannot spend too much time in the study of a patient who shows beginning chronic arthritis, to endeavor to prevent the progress of the disease and to prevent a life of more or less invalidism. No matter how tedious, and no matter how expensive it is for the patient to be scientifically studied in this condition, it will pay him and his physician for the outlay to arrive at the best management of his disease.

THE CHARACTERISTICS OF IMMUNITY IN SYPHILIS

Before the discovery of the *Spirochaeta pallida* (*Treponema pallidum*) by Schaudinn there exists a reasonable suspicion that the then unknown parasite of syphilis was one which passed through distinct cycles of development within the human host, thus accounting for the differences in the lesions observed in the classical three stages of the disease. This explanation for the variations in the lesions of syphilis collapsed with the earliest investigations made after the causative organism had been identified, for it was at once found that there was no difference in its appearance and characteristics whether it was examined in chancres, secondary eruptions, congenital lesions in deep-seated organs, or even in tertiary lesions, where it can be found sparsely distributed. Later investigations supplemented the evidence of morphologic identity by showing that biologically the organism is the same, since syphilitic material from lesions of any stage when inoculated into susceptible anthropoids gives rise always to the same sort of lesion, the primary chancre. From an extensive study of the historical facts and experimental investigations, with particular reference to the immunologic process of the disease, Levaditi of the Paris Pasteur Institute has developed an interesting and plausible conception of the processes which follow infection with syphilis, and which cause the peculiar development in stages that characterize its course in man.¹

While it is universally recognized that a strong degree of immunity is developed in syphilis, yet it is also recognized that this immunity is not absolutely protective and that it manifests itself in various ways. Persons with a definite history of syphilis may again acquire a primary lesion and develop the usual sequence of manifestations, and an individual may have multiple primary lesions, but neither of these occurrences is common. As a rule the existence of syphilitic lesions, whether active, quiescent or apparently healed, guarantees the individual against a new infection, and numerous actual experiments have established this protection. Now this condition of resistance to infection in syphilis is somewhat

peculiar, in that at the same time the protected individual may be, and usually is, harboring living organisms which may even be actively engaged in causing injury to his tissues. This is quite different from the ordinary conception of immunity, which implies that the immunity is the result of a refractory state incompatible with the life of the infectious agent. As a matter of fact, the immunity in syphilis is really not absolute but relative; during the period of incubation, and during the early stages of the history of the chancre, a second inoculation may result in the formation of more or less typical primary lesions; the later in the disease the less frequently and less typically will successful results be obtained. After the chancre is well developed, and during the secondary stage, inoculation with active virus under the skin may produce atypical lesions, or lesions resembling those of the secondary stage, although to such doses of virus as are commonly received by natural means of infection there will usually be no reaction. In the tertiary stage there is almost absolute insusceptibility to infection by inoculation, either natural or artificial, in spite of the fact that at the same time within the tissues a localization of a very small number of organisms coming from the patient's blood will produce large, rapidly spreading lesions, with great destruction of tissues, the gummas.

These apparently contradictory facts Levaditi explains in the following hypothesis: During the period of incubation, and before the primary sore appears, the parasites invade the body, for during this stage in experimental animals the virus can be found in the internal organs, particularly the spleen. This invasion causes the development of immune bodies, which soon are manifested by a partial refractory condition of the skin to further infection by natural exposure to syphilitic virus; this resistance is slight during the early stages of chancre formation, but is well developed by the time of the onset of secondary lesions, although not usually so complete that it may not be overcome by inoculation with a sufficiently large quantity of active virus. During the secondary stage we find that the lesions are chiefly of an inflammatory character, with evidence of great resistance by the tissues, which suffer comparatively little injury, in spite of the presence in these lesions of very great numbers of parasites; whereas in the tertiary stage, when the resistance to infection coming from without is highly developed, the lesions show great tissue destruction produced by an extremely small number of parasites.

Since the parasite seems to be the same in all conditions and stages of the disease, the differences in the effects produced are to be accounted for by differences in the resistance of the host to the invading organism. Levaditi suggests that the resistance developed during the primary stage may be sufficient to hold the parasites in check for a time, until they acquire a certain degree of immunity of their own to the antibodies of the host; they then enter the blood and set up a generalized

1. Levaditi, C.: De l'immunité acquise dans la syphilis, Ztschr. f. Immunitätsforsch. Referate, 1910, II, 277.

infection, characteristic of the secondary stage. In reaction to the infection of this stage greater quantities of antibodies are formed, which suppress the growth of the parasites to a large degree, although not destroying all of them. In the course of time the tissues themselves, however, may acquire a hypersensitive condition, so that even a few spirochetes may be able to cause extensive local necrosis, characteristic of the gumma of the tertiary stage. It is of course possible for the host to develop sufficiently great amounts of antibodies to destroy all the infecting organisms, thus accounting for those cases in which one or both of the last two stages of the disease are not manifested. Tertiary lesions as a rule, however, develop in spite of a highly developed resistance to the parasites of syphilis, which is shown by the difficulty or impossibility of producing a new infection by inoculation with new virus; presumably, therefore, the lesions of the tertiary stage are produced by organisms which are refractory to the antibodies of the host, but which are growing in tissues that have become hypersensitive or anaphylactic to the syphilitic virus. On this basis the efficiency of iodids in the tertiary stage would be ascribable to their action on the tissues, which they render less sensitive, or antianaphylactic, rather than to an action on the parasite comparable to that of mercury in the earlier stages.

These speculations of Levaditi have much to commend them as worthy of serious consideration, and to those who are familiar with the features of infection and immunity manifested in the trypanosome and spirillary diseases, on which much of Levaditi's reasoning is based, they will seem to be well grounded and far from visionary.

A NATIONAL DEPARTMENT OF HEALTH

Since the introduction in the Senate, by Senator Owen, of the bill providing for the establishment of a federal department of health, there has been much discussion in both the scientific and the secular press regarding the proposed measure. Several congressional committee meetings have been held at which appeared those favoring and those opposing the measure. Both proponents and opponents, however, at the committee meetings and in the public press, have dealt largely in general statements. No definite scheme has been submitted as a basis of discussion or action; and only general—and in the main irrelevant—objections have been advanced. This week we publish an article by Dr. Young, who for twenty years has been connected with one branch of the government health work. In this article the question is presented in its broader aspect. So far as we are aware, this is the first attempt that has been made to bring together and to present in concrete form the various activities, relating directly or indirectly to public health, carried on in the several departments of the government.

A careful reading of the paper reveals two important points. First, while the government is doing a large amount of excellent health work, its efforts are scattered and more or less duplicated, and, in the interest of economy and of far more effective ultimate results, the various enterprises, so far as practicable, should be coordinated and brought under one general head. Second, the problem of unifying all these enterprises and bringing them into one department or bureau is not so complex as some suppose, and yet it is a problem whose solution should not be attempted without careful study of existing conditions in order that reorganization may not result in halting or hindering some of the good work now being done.

As the first definite outline of a national department of health, Dr. Young's article is deserving of careful and critical study. Probably few will agree with him in all his conclusions, but the paper will serve as a basis for that common-sense, dispassionate and logical discussion of the problems involved which is needed if we are to secure satisfactory constructive legislation. The importance of the subject and the necessity of a provision for the health of the public are admitted by all—all, that is, except those having a faddistic or mercenary interest in the perpetuation of existing conditions. The only question on which there is any room for a difference of opinion is: In what way should the government's health activities be organized so as to result in the highest good to all the people?

The organization of a new department of our national government is an administrative problem of great importance, which can scarcely be solved by sweeping general statements. Dr. Young's contribution is of great value, especially in that it offers a tangible basis for discussion and can be taken as a starting-point for actual constructive efforts.

THE PURIFICATION OF WATER BY STORAGE

It has long been known that when cholera vibrios or typhoid bacilli are added to raw river water under laboratory conditions of experiment these pathogenic microbes die off rather rapidly; over 99 per cent. of the two species mentioned are destroyed within the first week. The inference seems justified that the longer a contaminated water can be kept from reaching the consumer the less likely is it to be the bearer of infection. The time element is probably more important than any other in the familiar process of the self-purification of streams, and its effect is particularly marked when water is retained for any considerable period in storage reservoirs.

In some cases the principle of purification by storage has been recognized and taken advantage of by the officials in charge of municipal water-supplies, but, on

the other hand, storage has been looked on often merely as a safeguard against drought and has not been utilized to its full value as a protection against water-borne infection.

This seems, for example, to have been until recently the case in London where, it is stated, the two large Staines reservoirs with a total capacity of 3,338 million gallons had their inlet and outlet pipes in the same towers, thus rendering impossible any proper circulation of the water. The work of Houston,¹ however, has drawn attention to the influence of storage on the character of the London supply, and should go far to make the beneficial effect of water storage more generally appreciated.

Briefly speaking, storage reduces the amount of suspended matter, the amount of "free ammonia" and of "oxygen absorbed" and removes some of the color; the hardness also is usually decreased. The number of bacteria of all sorts is diminished by storage, and this diminution is especially marked in case of the excremental bacteria, including the typical *Bacillus coli*. Indeed, Houston's work demonstrates that storage "reduces the number of typical *B. coli* to a proportionately greater extent than it reduces the number of bacteria of all sorts." As a prefiltration process it lengthens the life of the filter and produces uniformity in the character of the water delivered to the filtration beds.

The important fact is brought out also in the Report of the Metropolitan Water Board that London is not really drinking filtered raw river water, but river water which by storage processes has been bacterially purified to a remarkable extent antecedent to filtration. In spite, therefore, of the somewhat unsavory origin of much of the river water which serves as the source of the London supply, the water actually distributed to the consumers is of a high degree of bacterial purity. It seems very unlikely that any noteworthy portion of the typhoid fever in London at the present time is water-borne. At all events the death-rate from this disease is as low (3 per 100,000 inhabitants in 1909!) as in those cities that are provided with a supply of known and unexceptionable purity.

Curiously enough, some of the English authorities now appear inclined to attribute more importance to storage than to filtration in the purification of polluted river water. It does not seem necessary, however, to place the two processes in antithesis. Sand filtration, even when a raw and rather highly contaminated water is directly applied to the filter bed, has abundantly demonstrated its efficiency as a means of reducing typhoid infection. But it is indeed true that the beneficial effects of storage need to be just as widely known; in many cases this important process of purification can be taken advantage of with safety and economy.

Current Comment

THE DISINFECTION OF THE HANDS OF TYPHOID CARRIERS

The well-known difficulty of checking completely and permanently the excretion of typhoid bacilli from the bodies of "carriers" is leading to a search for other measures likely to avoid or lessen the danger to the community which is involved in the existence of these "walking germ-factories." Obvious measures are the prohibition to them of certain occupations, and instruction in habits of personal cleanliness. The motive for the latter precaution is readily found in the high degree of peril to which the family and immediate associates of the carriers are exposed. Clear and emphatic descriptions of the consequences to family and friends likely to follow from neglect will in many cases lead to willing compliance with instructions. The most effective method of obtaining hand-disinfection is made the subject of a recent study by Gachtgens,² a writer well known for his researches in connection with the intensive campaign against typhoid in the Rhine provinces. In this study, hands soiled with the infectious material have been subjected to various cleansing processes and then carefully tested for the survival of typhoid and colon bacilli. Thorough washing with soap and water, especially when followed by rinsing in fresh water and wiping on a clean individual towel, diminishes enormously the danger of infection and may in some cases lead to entire removal of the intestinal microbes from the infected hands. Since in some cases, however, this procedure does not effect complete removal of the adhering germs, Gachtgens recommends for greater security the use of some disinfectant. In his experiments formaldehyd soap solution, alkaline hypochlorite solution, hydrogen peroxid and even phenol proved unsuitable for the purpose, but good results were obtained with alcohol, especially in the form of eau de cologne and the ordinary cooking alcohol (*Brennspiritus*).

FISH AS FOOD

The enhanced cost of living in all civilized countries has directed attention to the less expensive forms of food. It has been said that the production of wheat is not keeping pace with the increase in population and that some more productive substitute must be found for it. Meat, likewise, for reasons not to be discussed here, is becoming relatively scarcer, and consequently so much more expensive as to portend at no distant time its compulsory partial abandonment as an article of diet by the poorer portion of the population. A more extensive use of fish has been suggested as one way out of the difficulty. As reported in our London Letter, at a recent meeting of the Sanitary Inspectors' Association in London, Sir James Crichton-Browne remarked on the value of fish as food, especially for the poor; from a physiologic standpoint it ranks second only to meat, containing somewhat less of protein but often more fat, while being far less expensive. Salmon is found the equal of lean

1. Report of the Metropolitan Water Board, 1905-1910.

2. Arch. f. Hyg., 1910, 73, p. 233.

meat in food value, and a pound and a half of cod is equal in nutritive value to a pound of lean beef, while the cost is very much less. Improved transportation facilities and methods of distribution make fish available as food to a much wider extent than formerly. At present, on account of fashion, prejudice, taste, etc., many of the coarser kinds of fish are tabooed, although of equal or greater nutritive value than those that are more popular. With present measures of conservation of fish and fisheries extended, along with the conservation of our other natural resources, and with proper encouragement in the use of this form of nitrogenous food, there would be an enormous development in the fishing industry and an accompanying economic saving to the people, while still maintaining the public health by a high plane of living in the presence of a waning meat supply.

TWO REMEDIES FOR RACE SUICIDE

"The best crop is the baby crop," said Mr. Roosevelt at Ames, Iowa, recently. True, but what shall it profit a nation if it produce ever so large a crop of babies but fail to keep them alive until they grow to years of maturity and usefulness? That nation is the strongest which has the largest number of mature, healthy and capable men and women. Mr. Roosevelt has done great service in decrying race suicide and urging a larger birth-rate. There are, however, two ways in which a nation can annihilate itself. One is by a diminishing birth-rate and the other is by an increasing death-rate among infants and young adults. The child which dies before it reaches maturity is a dead loss to the community. If Mr. Roosevelt will take up, with his accustomed vigor, the conservation of existing lives, in conjunction with his campaign for an increase in the number of new lives, as a combined remedy for race suicide, he will aid a growing and inevitable reform and will vastly increase the obligations of the country to him for his services.

ITALIAN IMMIGRANTS AND TUBERCULOSIS

It is reported that tuberculosis is increasing in Italy, and the reason given is that many of the immigrants returning from the United States are consumptive. How much increase there is, and how much truth there is in the statement that the increase is due to the immigrants from America, we do not know. It would not be at all strange, however, if there were some foundation of facts to warrant the statement. Most of the immigrants from southern Italy have been country laborers at home. When they reach this country, they swarm to the slums of our large cities, and naturally become easy prey to tuberculosis and to other diseases favored by the new conditions and modes of life. In their native country they lived chiefly in the open air under a mild and equable climate, where they were less subject to direct infection, to artificial conditions of life, and to violent extremes of temperature; their new life in all its phases is conducive to the changing of healthy men into consumptives. It would be better for these

Italian immigrants, as well as for us, if they would go into the agricultural districts, where they are really more needed and where they would be better off physically and in every other way. That the Italian immigrant, established in a suitable rural environment, and in a climate not too unlike that of his native country, is capable of becoming, with little assistance, a self-sustaining and useful citizen, is shown by the success of the Italian colony of St. Helena in North Carolina.

UNHYGIENIC CIGAR-MAKING

A matter worth the attention of health authorities is afforded by the custom among cigar-makers of biting off the tobacco at the end with their teeth and finishing the cigar by plastering down the outside leaves with saliva. We cannot say how extensive this custom is, but from our acquaintance with cigar-makers it appears to be not uncommon. The excuse given for this insanitary method is that, while the managers do not actually demand it, it is practically impossible to finish a cigar to meet the demands of the foremen without resorting to it. The practice if generally known ought to diminish the sale of cigars on esthetic considerations alone, to say nothing of the very obvious danger of the transmission of disease—tuberculosis, for example, which is quite prevalent among cigar-makers. The practice is injurious not only to the customer, but to the workman as well. The frequent occurrence of functional stomach disease, among them, chiefly hyperchlorhydria, is at least greatly favored by this practice.

EPIDEMIC POLIOMYELITIS—INFANTILE PARALYSIS

We have received many requests for information on various points regarding poliomyelitis, showing the desire for more information than is to be found in the majority of text-books. These requests have come from all parts of the country, emphasizing what is known to be a fact—that this disease is epidemic in many localities. On account of this desire for information, we have prepared, and publish this week, a short article on the subject. In addition there is in this issue an abstract of a paper by Robertson and Chesley on the pathology and bacteriology, and an article by Silver on the surgical treatment, together with the discussion which took place thereon in the Section on Nervous and Mental Diseases at the St. Louis session of the Association. From the history of the past few years it would seem that the disease is increasing in frequency; it is certainly a subject that needs the most careful thought on the part of the hygienist and of the family physician. The public should be taught that the disease is a contagious one. While this contagiousness may not be great—probably one-quarter as great as that of scarlet fever—the danger is sufficient to justify the isolation of actual and suspected cases. The disease should be reported, and health officers should endeavor to make clear the dangers which are sufficient to warrant moderate quarantine. Probably the infectious period does not extend much beyond the acute period. The observations of

Flexner that the mucosa of the pharynx contains an unusual proportion of the virus would indicate that the secretions of the throat may form one of the sources of the infectious material. Further investigation should be directed to the possibility of conveyance of the virus by the feces, urine and perspiration. Physicians should impress on their clientele the importance of prompt medical supervision in cases of acute intestinal disturbances in children in localities in which the epidemic is prevailing. Careful records of such cases should be kept, so that if poliomyelitis develops, the preliminary symptoms could be carefully reviewed. It is by such careful observation of the preliminary symptoms by a large number of observers that we may hope to learn more of the initial symptoms than is now known; this will assist in the early diagnosis of the disease. Next week we shall publish a paper from Dr. Flexner, in which he reviews the experimental work on the disease and what it has revealed.

Medical News

CALIFORNIA

Personal.—Dr. A. Miles Taylor, San Francisco, chief surgeon of the Northwestern Pacific Railroad, gave a dinner August 27 to the surgeons of the road who had been in attendance at the meeting of the Pacific Railway Surgeons' Association.—Dr. Charles W. Decker, Palo Alto, is said to be seriously ill with rheumatism in San Francisco.—Dr. Louis P. Howe, San Francisco, has been appointed local surgeon of the Western Pacific Railroad for San Francisco and vicinity.

Stanford Adds to Medical School.—A number of additions are being made to the medical school at Stanford University. Last year one wing of the museum building was set aside for an anatomy building, and this year two additional wings are being used, one to be devoted to bacteriology under the charge of Dr. Hans Zinsser, a newly appointed member of the faculty, and the other to pharmacology under the charge of another new member of the faculty, Dr. Albert C. Crawford.

Items About Hospitals.—A new hospital is to be erected on the east side of Stockton by the San Joaquin Hospital Association, to cost about \$75,000. The hospital will occupy a site of eight or nine acres, and it is said subscriptions amounting to \$50,000 have already been secured.—A new hospital is soon to be opened at Visalia in the former home of Dr. Neame. It has been purchased and remodeled at a cost of about \$30,000.—Articles incorporating the Oakland Maternity Hospital, with a capital stock of \$15,000, have been filed with the county clerk of Tulare county.—The work of construction on the Kings County Hospital, Hanford, was started August 1.—Dr. Albert J. Elliott has formed a company with a capital stock of \$50,000 to build and conduct a hospital for helpless invalids, under the name of the San Diego General Hospital Company.—The Pacific Lumber Hospital, Scotia, was incorporated August 20.—The King's Daughters of Oakland are making earnest efforts to secure the \$42,000 required to build the new building of the California King's Daughters' Home for Incurables.

COLORADO

Personal.—Dr. Henry W. Rover, Denver, has returned after six months' travel in Europe.—Dr. and Mrs. Horace G. Wetherill, Denver, left September 3 to attend the International Congress of Obstetrics and Gynecology in St. Petersburg.—Dr. Thomas Damhey has resigned as resident physician at the Denver County Hospital.—Dr. Robert S. Allen, physician of Denver County, is recovering from appendicitis for which he was operated on August 23 at St. Luke's Hospital.

GEORGIA

District Society Meeting.—The sixth semi-annual meeting of the Fourth District Medical Society will be held in Pine- dale, September 20, under the presidency of Dr. T. Neal Kitchens, Columbus. The program shows several interesting titles, such as "Christian Science, the Religio-Medical Masquerade," "Why a Physician Should Identify Himself with the Medical Society," "Professional Courtesy," and "What a General Practitioner Ought to Be."

The La Grange Sanatorium.—The legislature of Georgia has appropriated \$30,000 for completing the buildings of the La Grange Sanatorium, and \$20,000 for maintenance of the institution for 1911. At the meeting of the executive committee of the trustees, held in Atlanta August 27, plans were perfected for completing the buildings and preparing for patients. They hope to have the institution ready to receive patients January 1, and expect to be able to accommodate 100.

ILLINOIS

Patten Helps Hospital.—George W. Patten, Evanston, has donated \$500,000 to the Evanston Hospital Association. The gift creates the "Agnes and Louisa Patten Fund" and is to make up a part of the endowment fund of the institution, only the income of which can be used.

Personal.—Dr. and Mrs. A. D. Bridgman, Decatur, celebrated their golden wedding anniversary August 31.—Dr. Herbert C. Jones, Decatur, has returned from Europe.—Dr. Porter W. Hopkins, Cullom, has sailed for England.—Dr. Hiram T. Hardy, Kaneville, who was operated on for the removal of gall-stones August 27, is reported to be doing well.

The New Cook County Hospital.—A plaster cast model of the new Cook County Hospital, for which \$3,000,000 has been appropriated, shows the twelve proposed new structures, six medical buildings, two surgical buildings, one administration building, a detention building, a pathologic building, and a morgue. Among the features of the plans submitted by the committee are roof gardens on the ward buildings and outdoor camps for tuberculosis patients.

Chicago

Personal.—Dr. and Mrs. Arthur Dean Bevan have returned from Europe.—Dr. John Edwin Rhodes has returned from a month's outing in British Columbia.—Dr. and Mrs. David Fiske have returned from Europe.

Increases Requirements.—Northwestern University announces that the requirements for admission to its medical school hereafter will be two years in college. Under present conditions students registering for the medical department are required to show only one year of college work. The new plan is expected to go into effect next year.

Increased Death Rate.—The report of the Department of Health for the first eight months of 1910 shows 22,808 deaths as compared with 20,822 in the first eight months of 1909, an increase for the year 1910 of 1986 or 6 per cent., the respective annual death rates per 1,000 being 15 and 14.1. The chief increases noted were pneumonia from 3,372 to 4,133, an increase of 761, and diarrheal diseases of infants, from 1,576 to 2,265, an increase of 389.—During the week ended September 9, 27 new cases of diphtheria were received at the Isolation hospital and 100 cases were reported.

Ground Broken for Jewish Hospital.—Orthodox Jews raised a sum estimated at \$10,000, September 11, at the groundbreaking ceremony for the establishment of the Maimonides Kosher Hospital, at South California and Ogden avenues. The chief privileges sold were turning of the first clod of earth, placing the name on the golden scroll, and burning the mortgage. The building is to be six stories high, will cost about \$175,000, and will accommodate 175 patients, 75 of whom will be free patients. The first wing of the hospital is expected to be completed in less than a year.

IOWA

Hospital News.—The Sisters of St. Francis of the Home for the Aged, Dubuque, are having constructed a new chapel and hospital addition which will be completed in about two months. The hospital will be for the use of sick sisters of the order and for those advanced in years and unable to work.—The lease of the LeMars Hospital having expired, the hospital has been closed.

Personal.—Dr. George Donohoe, assistant physician at the State Hospital, Independence, has been appointed superintendent of the State Hospital for Inebriates, Knoxville, vice Dr.

Herbert S. Miner, resigned.—Dr. John A. White, Olin, who was operated on at a sanitarium at Anamosa, August 18, for gall-stones, is reported to be doing well.—Dr. Henry G. Langworthy is building a private infirmary at Dubuque.

KENTUCKY

Personal.—Dr. Ernest B. Bradley, Lexington, city bacteriologist, has been appointed health officer of Fayette County, vice Dr. William J. Foley, deceased.—Dr. Porter Prather, Lexington, has been elected a representative of the fiscal court of Fayette county.—Dr. John B. House, Scottsville, is reported to be critically ill.

Will Label Adulterations.—As a result of the prosecutions of the local ice cream dealers charged with alleged violations of the pure food law a compromise has been effected between R. M. Allen, chief of the State Pure Food Department, and the attorneys for the ice cream dealers by which the dealers agree to label all of their products which contain gelatin, coloring matter, etc.

Convicted of Manslaughter.—In the case of the state against Dr. Fred D. Marcum, Louisa, charged with killing John Whittaker, the jury is said to have brought in a verdict of manslaughter and fixed the punishment at seven years' imprisonment in the penitentiary. The killing occurred on a train two years ago, when Dr. Marcum was marshal of Louisa, and was requested by the conductor to arrest Whittaker and three companions for alleged disorderly conduct. They resisted arrest and in the fight which followed, Whittaker was fatally shot. At the first trial the jury disagreed.

Asks Modification of Ruling.—The Shelby County Dairymen's Association has passed resolutions asking the State Board of Health to modify its recent ruling which requires a dairyman in whose barn cows affected with tuberculosis have been found to have it disinfected by an inspector selected by the State Board of Health and paid for by the dairymen at the rate of \$10.00 per day for the time so employed. The dairymen claim that they are willing to do all the necessary disinfecting, but protest against the employment of the State Board of Health inspectors as an unnecessary expense. They contend that the work can be done just as thoroughly and at much less cost by the county boards of health. Their resolutions state that they are willing to have their barns disinfected according to the rules laid down by the State Board of Health, by and under the direction of the county board.

Water Supply and Typhoid.—An interesting report has been published by the superintendent of the Louisville Water Works which shows the percentage, for the past four years, of deaths from typhoid fever in the city. The filter plant of the Louisville Water Works was put in operation in August, 1909. The deaths from typhoid fever in 1906 were 137, for 1907, 168, for 1908, 109, and for 1909, 96, the average death rate for the four years being 129. For the year ended August 1, 1910, in which the filter was in operation the total number of deaths from typhoid fever was 73. It is estimated that the mains of the water works system were fairly well cleaned by November, 1909, and that only filtered water circulated through them. The total number of deaths from November 1, 1909, to August 1, 1910, was 38. Comparing these figures with previous years shows a reduction of 60 per cent. in the number of deaths from typhoid fever over the average of the preceding years.

Proposed New City Hospital.—The Hospital Commission of Louisville has submitted a report to the mayor in regard to their plans for the proposed new million-dollar hospital for the city. It recommends the present site of the hospital for the new building because of the central location and easy access, and condemns the present hospital as being far below a modern public institution. With an estimated population of 240,000 the commission recommends a building of not less than 350 beds. The present location comprises about 6 acres. The new building is to be provided with well equipped laboratories; of fire-proof construction; roofs arranged for out-door air and sunlight for convalescents and the building to be a modification of the condensed and pavilion plans. A special department is to be provided for insane patients pending their commitment to asylums. Ample accommodations for the out-patient department with baths and lockers is planned. A mortuary chapel and pathologic building are also arranged. A separate power house and nurses' home will be provided for in the plans. Ample arrangements will be made for the housing and care of patients at present in the hospital before the building is demolished.

MARYLAND

Personal.—Dr. Lewis Mines Allen, associate professor of obstetrics in the University of Maryland, has resigned to engage in general practice in Winchester, Va.—Dr. Francis E. Harrington has been appointed secretary of the board of health of Cumberland.

Better Medical Practice Act Wanted.—The *Bulletin of the Medical and Chirurgical Faculty of Maryland* discusses the evils of the medical practice act in Maryland, and starts an agitation for "a new model practice law the central plank of which should be the single-board idea" . . . "After the brilliant series of successes achieved by the faculty during the last session of the legislature, there can be little doubt that the lawmakers who will assemble at Annapolis in 1912 will enact into law any essentially good medical practice act which has the support of a united medical profession."

Baltimore

The Floating Hospital for Sick Babies.—Dr. P. Martin Bruns has arranged to deliver a series of illustrated lectures on the need of a floating hospital for sick babies. His idea is to have one or two barges for this purpose towed by tugs, and estimates the initial expense at \$20,000 and the annual expense at \$20,000.

Personal.—Dr. James Bordley has returned from a thousand-mile automobile trip through the middle states.—Dr. John T. Powers has resigned from the staff of the Bayview Hospital.—Dr. G. Milton Linthicum, who has been ill with typhoid fever, has had a relapse and returned from Atlantic City to the Maryland General Hospital, September 5.

MASSACHUSETTS

New Ruling on Liquor Law.—In the District Court of Middleboro, August 20, Judge Allan gave a new interpretation of the liquor law of the state, when he decided that a Middleboro druggist who sold liquor on a prescription from a Bridgewater physician had violated the law, and that the Bridgewater physician could not be held to be practicing in Middleboro unless he had an office in the latter town.

Personal.—Dr. Charles H. Fessenden, Newton Center, has been elected director for the New England Division of the North American Esperanto Association.—Dr. Thomas F. Harrington, Boston, director of school hygiene, has returned from Europe.—Dr. John T. Cahill has been elected mayor of Lawrence.—Dr. G. S. Dodds of the biologic laboratory, Woods Hole, has been appointed a member of the faculty of the Medical Department of St. Louis University.—Dr. Francis H. Slack, director of the bacteriologic laboratory of the Boston Health Department, has resigned to accept an appointment as instructor of bacteriology of the Kansas State College, Manhattan.—Dr. Winfred O. Wilder has been appointed medical inspector of schools of Pittsfield.

MICHIGAN

Personal.—Dr. Herbert W. Yemans, Detroit, has been elected vice-president of the North American Esperanto Association.—Dr. R. Grace Hendrick, Jackson, is going to Europe.

Work of County Antituberculosis Society.—The Houghton County Antituberculosis Society, which is making a request for funds for the furtherance of its work, states that the visiting nurse employed now has 82 patients under her care. Of these 25 are sleeping in the open air under the advice and direction of the society. Since the establishment of the service in February, 20 patients have died; 5 families have been moved to more sanitary homes, and 12 families are receiving daily from one to two quarts of milk provided by the society or by the Associated Charities of Calumet.

NEW JERSEY

Personal.—Dr. and Mrs. Walter Reynolds, Atlantic City, sailed for Europe September 10.—Dr. M. Jones Luffbary, Glassboro is reported to be seriously ill with tuberculosis.—Dr. M. A. Davis, Vineland, was operated on in Cooper Hospital, Camden, September 9, for appendicitis.

Money for New Children's Seashore Home.—Mr. Max Bamberger, Philadelphia, who died at Kissengen, Germany, August 5, left a bequest of \$40,000, "to erect and maintain at Atlantic City, or at some point in the vicinity thereof, a home similar to the Children's Seashore Home, for the accommodation and treatment of invalid Jewish women and children, to be known as the Max and Sarah Bamberger Seashore

Home." It is the desire of the testator that children of Philadelphia be given the preference.

NEW YORK

Personal.—Dr. E. S. McClellan of Saranac Lake, president of the local Board of Health, was struck by a train and severely injured. There is slight hope of his recovery.—Dr. John H. Martin has been elected president and Dr. John C. S. Lappeus, secretary of the newly organized Mutual Protective Association of Doctors of the City of Binghamton.

New Tuberculosis Hospitals.—An institution for the treatment of tuberculosis has been completed and was to be opened in East Bloomfield, Ontario county, September 15. This sanitarium was built at a cost of \$15,000.—The Board of Supervisors of Canandaigua on September 3 voted \$3,000 for the finishing and equipment of the new tuberculosis hospital, and \$1,200 for maintenance of the present institution for October, November and December.

New York City

Personal.—Dr. Mariano Scimeca has recovered his son who was kidnaped June 21.—Dr. Aaron B. Cohen, who severed his connection with the Eastern District Hospital, Brooklyn, September 1, was presented with a silver loving-cup and a set of surgical instruments at a dinner given in his honor August 31.

Clinic for Italian Consumptives.—The Board of Health maintains a clinic for Italian consumptives at 339 East 109th Street. Although this clinic has been in existence for three years, the Italian public has not been made aware of the fact to any extent, and a request has been made that the existence of this institution should be more widely published.

Plan for Better Health Work.—Dr. Lederle has asked the Board of Estimate and Apportionment for a sum which is \$1,328,855 in excess of the allowance for this year. This request has brought to light the fact that there are in this city fewer inspectors than there were ten years ago and that there exist three times the number of contagious diseases. The largest increase asked for is \$486,056, in the division of hospitals, while the division of child hygiene has asked for an increase of \$320,545. This increase is asked so that every school in the city, including kindergartens, parochial schools, industrial schools and the school of correction may all be brought under the supervision of the health board. It is also planned to open winter headquarters corresponding to the recreation piers and summer vacation schools, where mothers will be taught the year round to care for their babies.

Buffalo

Memorial to Sanitarian.—It is proposed to name the new hospital for contagious diseases after the late Dr. Ernest Wende, as a memorial of his services as a sanitarian and health officer.

Addition to Medical Building.—A new addition to the medical building of the University of Buffalo Medical Department is being constructed and will cost, when completed, about \$20,000. The first floor of this addition will be occupied by the chemical laboratory and the second floor will be given over to rooms for research. Larger quarters in the old building will also be provided for the department of pathology.

OHIO

New Location for College.—Following the adoption of a resolution of the new Cincinnati Hospital Commission, declaring its intention of appropriating the property between Eden Avenue and Vine Street, it was announced, September 1, that the commission, after acquiring the property, would donate a hilltop site for the new buildings for the Ohio-Miami Medical School.

Personal.—Dr. Martin H. Fischer has been appointed professor of physiology, Dr. H. Knower, of Johns Hopkins Medical School, professor of practical anatomy, and Dr. Julius H. Eichberg, professor of pharmacology in the Medical Department of the University of Cincinnati.—Dr. James E. Torrence, Hamilton, has returned after two months in St. Ignace, Mich., greatly improved in health.

Addition to College.—The Starling-Ohio Medical College is erecting an addition to the college building, to be used for laboratories at a cost of about \$10,000. Mr. Roy Graham Hoskins, Ph.D., formerly teaching fellow in physiology at Harvard Medical School, has been secured as professor of physiology and will devote all of his time to teaching. He will be assisted by Dr. Clayton C. McPeck.

PENNSYLVANIA

Personal.—Dr. John W. Luther, chief surgeon of the Palmetton Hospital, Mauch Chunk, was operated on in the University Hospital for appendicitis, September 8.—Dr. and Mrs. Wm. J. Hickson, Pittsburg, are going to Europe.—Dr. Allan W. Urmson, New Castle, has been appointed squadron surgeon with the rank of captain in the Pennsylvania National Guard.—Dr. Francis N. Baker, of Media, sailed September 3 for an extended trip through Europe.

Philadelphia

Another Public Bath House.—A permit has been granted for the erection of a public bath house for the city of Philadelphia at the corner of Montrose and Darien Streets. The building will measure 34x95 feet and will cost \$15,000.

Soothing Syrup Maker Held.—Mrs. M. M. Harvey, maker of "Mother's Comfort," for whom a warrant was sworn out several weeks ago, was finally arrested and given a hearing before Magistrate Beaton on September 6. She was held in \$500 bail for court.

Vaccination Rule Changed.—Under revision of the compulsory vaccination law, children who have been vaccinated within five years may be admitted to the public schools. Heretofore a certificate of vaccination was required every three years. This change was made after a careful investigation and on an authoritative statement that the period of five years was sufficient.

Personal.—Dr. Charles F. Judson sailed for Europe September 10.—Dr. H. G. Wetherill, Denver, who sailed for Europe September 10 to attend the Gynecologic Congress, in St. Petersburg, was given a dinner at the University Club, September 6, by Dr. Montgomery.—Dr. Sidney Stephenson, of England, who is to make an address before the American Academy of Ophthalmology and Otolaryngology in Cincinnati, has been a guest of Dr. Wendell Reber.

Facts Brought Out by Milk Inquiry.—At the milk inquiry held in the mayor's office on September 3, Dr. Neff showed that 89.2 per cent. of the milk coming to Philadelphia is over 55 degrees on the platform and 98.2 per cent. is over 50 degrees. Mr. Boyd of the Pennsylvania Railroad reported that refrigerator cars and the refrigeration of the milk in transit would cost a mill a quart, or less. Farmers testified that refrigerating milk had saved its cost for them by preventing milk from souring.

Health Report.—There has been an increase of 77 in the number of cases of typhoid fever reported to the health bureau in the seven days ending September 10. Ten deaths were reported as compared with 4 for the preceding week. These cases are not limited to the city proper as 29 cases have been reported from the York Road, Main Line and Lansdowne suburbs. There is a decrease in the number of cases of whooping cough, 16 being reported this week as compared with 27 last. There were also 11 cases of infantile paralysis reported, an increase of 4.

New Playground for City's Poor.—Plans for the transformation of Starr Garden Park into a model recreation center have been made. A building will be erected 44x144 feet. This will contain shower baths for both sexes, gymnasium, club, class, reading and game rooms and also administrative and teachers' quarters. The building will be of colonial architecture, of Flemish bond brick with limestone trimmings and the floors will be of cement and the building fireproof throughout. The structure will be erected on a plot of ground 400 feet long, at a cost of \$40,000. Improvements to the grounds, including the establishment of track, a wading pool, tennis courts and every facility for play and recreation will cost \$15,000.

Arrests in Pure Food Crusade.—Eleven ice cream manufacturers were arrested and arraigned before Magistrate Beaton, September 9. They were charged with adulterating their products and ten of the eleven pleaded guilty and paid fines of \$25 and costs each. Samples of their products examined by Professor LaWall, chemist for the department, and Dr. Randall Rosenberger, of Jefferson Hospital, were found to contain amyl acetate, ethyl acetate, butyric acid and furniture glue. The last was used instead of gelatin and on analysis was found to contain sulphurous acid or sulphur dioxide, and a bacteriologic examination showed each cubic centimeter of the glue contained 350,000 colonies of bacteria.—On September 9, Judge McPherson granted an order in the United States District Court directing the destruction of 822 cans of tomatoes, 9 barrels of catsup and 114 packages of ice cream recently seized by federal pure food authorities.

GENERAL NEWS

American Physicians in Mexico to Meet.—The International Medical Association of Mexico, an organization of American physicians residing and practicing in the republic, will be held in Juarez or El Paso the first week in November, under the presidency of Dr. C. E. Husk, Santa Barbara, Chihuahua.

Health Association Election.—At the thirty-eighth annual meeting of the American Public Health Association, held in Milwaukee, September 6 to 9, the following officers were elected: President, Dr. Robert M. Simpson, Winnipeg, Man.; vice-presidents, Drs. Fernando Lopez, Mexico City, Mexico; John Anderson, Washington, D. C., and Gerhard A. Bading, Milwaukee; secretary, Dr. William C. Woodward, Washington, D. C., and treasurer, T. H. Wine, New Haven, Conn.

Missouri Valley Physicians Elect.—At the annual meeting of the Missouri Valley Medical Association held in Council Bluffs, Iowa, September 1 and 2, Dr. Donald Macrae, Council Bluffs, was elected president; Dr. John M. Bell, St. Joseph, Mo., first vice-president; Dr. John M. Banister, Omaha, second vice-president; and Drs. Charles Wood Fessett, St. Joseph, Mo., and Thomas B. Lacey, Council Bluffs, were reelected secretary and treasurer respectively. The next semi-annual meeting will be held in St. Joseph, Mo., March 23.

The Cumberland Valley Meeting.—The eighth annual meeting of the Cumberland Valley Medical Association was held at Blue Mountain House, September 1. The following officers were elected: President, Dr. John B. McCreary, Shippensburg, Pa.; vice-president for Washington county, Md., Dr. C. J. Wingard, Funkstown; for Franklin county, Pa., Dr. John C. Gilland, Greencastle; for Cumberland county, Pa., Dr. Harry A. Spangler, Carlisle; secretary, Dr. John J. Coffman, Scotland, Pa. (reelected); assistant secretaries, Drs. John R. Laughlin, Hagerstown, Md., E. Roberts Plank, Carlisle, Pa., and Henry C. Devilbiss, Chambersburg, Pa., and treasurer, Dr. John J. Koser, Shippensburg, Pa.

Health of the Canal Zone.—The report of the Department of Sanitation of the Isthmian Canal Commission for July shows a death rate of 11.80 per 1,000 per annum, which is a little larger than that of July, 1909, but much smaller than that of the previous four years. There were 12 deaths of white employees, an annual rate per 1,000 of 10.37, while of the colored employees, 39 died, equivalent to an annual mortality of 12.32 per 1,000. Malaria caused 11 deaths; violence, 11; lobar pneumonia, 8; tuberculosis, 5; dysentery, 3; typhoid fever and hemoglobinuric fever, each 1, and other diseases, 11. No case of yellow fever, smallpox, or plague was brought to or originated on the isthmus during the month. As prophylactics 43,159 gallons of crude oil, 9,890 gallons of larvicide, 11.25 pounds of arsenic, 32 pounds of pyrethrum, 541 pounds of sulphate of copper, and 216 pounds of phenol were expended by the department during July.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Sept. 3, 1910.

Irish Vital Statistics

The official figures for 1909 which have just been issued, show that the population of Ireland is still decreasing, the loss by emigration more than wiping out the excess of births over deaths. In 1908 there was a slight gain of population (1853), the first for more than half a century. In 1909 the figures were as follows: Births, 102,759; deaths, 74,973; emigration, 28,676; decrease of population, 890. It is satisfactory that the deaths from tuberculosis continue to decrease; they numbered 10,594, which are 699 less than in 1908, in which year there was a decrease of 386. This result is attributed to the work of the Women's National Health Association, which has been described in previous letters.

Killed by Tattooing

An inquest has been held on a soldier, aged 21, who died from tuberculous meningitis, the result of tattooing on the right arm, which was followed by a tuberculous scar. The medical evidence was to the effect that tuberculosis might have been inoculated in consequence of the tattooist using a needle with which he had previously tattooed a person suffering from the disease, without proper disinfection of the needle, or that the tattooist might have been consumptive and put the needle in his mouth during the operation. Such a result from tattooing must be extremely rare. A few cases have been observed in this country in which local tuberculosis in the form of lupus has followed tattooing.

Outbreak of Cerebrospinal Meningitis

An outbreak of cerebrospinal meningitis has occurred at certain villages in Leicestershire. In all, 35 cases have so far been observed in an area of 50 square miles, the patients being mostly children between the ages of 2 and 11 years; 4 deaths are reported. As a precautionary measure, the schools have been closed. Three years ago a similar outbreak occurred in the neighboring town of Nottingham.

The Value of Fish as a Food

At the annual meeting of the Sanitary Inspectors' Association held at the Fishmongers' Hall, the president, Sir James Crichton Browne, delivered an address on "Food and Fish Supply" in which he emphasized the value of fish as a food, especially to the poor. Away from our coast towns fish hitherto has been regarded too much as an accessory, and too little as a staple article of diet. Many artisans and people of the middle class might with economic advantage raise their expenditure on fish. They fail to realize the comparative food value of the cheaper, or as they are unfortunately called, the poorer kinds of fish. From a physiologic standpoint fish is the next best thing to meat; 1½ pounds of cod are equal in food value to 1 pound of beef and cost not half the former. If a general call for fish would arise a vast development of the fishing industry would result and good digestible food would be made accessible to the poorest. This might prove a useful auxiliary in the campaign against tuberculosis. We have, as it were, lived on the wild life of the ocean, as our forefathers did on the wild life of the forest. But on the sea, as on the land, we must exchange the chase in a large measure for the ranch and the fold. We should have marine stock farms bordering all our coasts and be able to pride ourselves on our prize turbot and pedigreed cod.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 2, 1910.

The Campaign Against Alcoholism in the Army

Alcoholism and criminality due thereto, which are in general increasing among the civil population, are, on the contrary, diminishing in most of the European armies. This is notably so in France, where a series of official measures promulgated from 1892 to 1909 tends toward the prophylaxis of alcoholism in the army. All official distribution of brandy or rum has been suppressed in time of peace, and on campaign the distribution of a ration of 0.0625 liter of brandy per man per day is permitted only exceptionally and under rare circumstances, prescribed by the regulation. It is, moreover, absolutely forbidden to sell any brandy or alcoholic distilled liquor in the canteens or on the fields of maneuver. Fermented drinks, however, are still in general use. The moderate use of wine, beer or cider, according to the region, is even recommended and regulated as a hygienic measure and a national custom by the ministerial circulars. Although, thanks to these measures, the French soldier never indulges in alcohol in barracks, unfortunately alcohol still continues to permeate the army. The cause of the evil is outside of the barracks, in those "blind pigs," so numerous near the barracks and camps, where the soldier obtains alcoholic drinks, and contracts syphilis and gonorrhea. For a few years, official instruction in regard to the distribution of alcohol has been given to commissioned and non-commissioned officers and soldiers through lectures, pictures, etc., posted in the messes and dining-rooms. But this is not always sufficient to protect the soldier against the attraction of the saloon. The Red Cross, therefore, has begun to organize "soldiers' firesides" or clubhouses—places where the soldier is, so to speak, at home, where he may deposit his personal belongings, find paper and ink for correspondence, books, games and no alcohol. The military administration has authorized such establishments on condition that they shall be free from religious and political influences.

The Medical Studies of Rabelais

The important place held by the medical sciences in the work of Rabelais is well known. "Gargantua and Pantagruel" abounds in anatomic descriptions and dissertations on pathologic and therapeutic matters. What was the source of the medical knowledge of the great sixteenth-century writer? In a recent thesis for the doctorat *ès lettres* devoted to the work of Rabelais and defended before the Paris college of letters, M. Jean Plattard devoted a whole chapter to the medical

studies of Rabelais and to the place of the medical sciences in his work. M. Plattard showed that the medical bent of Rabelais was due to the fact that at the beginning of the sixteenth century theoretical medicine was entirely founded on treatises of the Greeks and Latins. Whoever knew Greek well could give an authoritative opinion on the interpretation of Galen and Hippocrates. The most technical works were studied by the philologists or "humanists," who had a better knowledge of ancient languages than practicing physicians had. Medicine was founded on "philosophy," in the large sense assigned to the word at that time. Rabelais came to study medicine through the example of his masters and through the natural operation of his humanistic curiosity. He brought to it an enthusiasm of his own and the extraordinary learning thus acquired was put to use in his writings.

New Press for Books for the Blind

M. E. Vaughan, director of the Hospice national des Quinze-Vingts, a hospital for the blind, has invented a little press which permits a 10-year-old child to print in the Braille alphabet without even knowing that alphabet. The operator touches ordinary characters; the machine automatically prints Braille characters. The number of books for the blind and especially for blind children is far too small; therefore this press is capable of rendering valuable service to libraries for the blind.

Employment of Dogs to Seek the Wounded

Lately, during the course of instruction of the sanitary service at Paris, some interesting experiments were made in regard to the finding of the wounded by dogs. The wounded were hidden among high bushes, behind bundles of hay, etc. Dogs brought to the field by the Société nationale du chien sanitaire found the wounded with surprising certainty and rapidity. The dogs worked even better and more quickly by night than by day. When a well-trained dog has gone over a field, even a difficult one, by night or by day, he leaves no wounded person overlooked, which is a point of the greatest importance.

The Renovation of Old Corks

About ten years ago the council of hygiene of the department of the Seine attempted to forbid all employment of old corks, even when cleaned, for bottles or containers of liquids to be taken internally. There exists, however, a trade in the renovation of corks, and the protests of the merchants affected compelled the council of hygiene to modify the order so as merely to impose on the renovators certain conditions, such as the boiling of the corks for a quarter of an hour in 2 per cent. sodium carbonate, followed by immersion for some hours in 1 per cent. sulphuric acid. These precautions appeared, however, insufficient and on the report of M. Guignard, director of the superior school of pharmacy at Paris, and member of the Académie de Médecine, the following rules for the sale of renovated corks have just been adopted: Corks gathered from the streets, from the Seine, from gutters, etc., must not be sold until they have been submitted to the action of live steam under a pressure of at least two atmospheres, the time of sterilization being not less than twenty minutes. Sterilized corks may be decolorized, provided the chemical used for whitening them shall be completely eliminated. Corks so treated may be put on sale only as "renovated sterilized corks."

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 2, 1910.

Death of Professor Henoch

A few weeks after the celebration of his ninetieth birthday the senior of pediatrics, Professor Henoch of Dresden, died. Senile weakness which compelled him even on his birthday to limit the reception of delegates as much as possible was increased by the excitement inseparable from the celebration, and in a short time led to fatal results. Henoch was not only one of the founders of modern pediatrics but a distinguished clinician and physician, a remarkable teacher and a striking personality. His academic activity began as assistant to his uncle, the renowned neurologist, Professor Romberg of Berlin. At this time he published his first notable work "Clinical Results from the University Polyclinic" (*Klinische Ergebnisse aus der Poliklinik der Universität*). As privat-docent (after 1859), he published the "Clinic of Abdominal Diseases" (*Die Klinik der Unterleibs-Krankheiten*) which in spite of the fact that it embraces three volumes has

appeared in three editions. His most noted work is "Lectures on Children's Diseases" which has appeared in a large number of editions and has been translated into many languages. He resigned his direction of the Berlin Children's Clinic in 1893. It distressed him not a little that he could not succeed in getting his extraordinary professorship converted into a regular one, and this dissatisfaction was greatly increased by the fact that what was refused him was assured to his successor, Professor Heubner, on his nomination. There can be little doubt that the Israelitish faith of Henoch was a marked factor in causing the refusal of his request.

Death of Professor von Recklinghausen

On the same day as Henoch, namely, August 26, the distinguished professor of pathology of Strasburg, von Recklinghausen died at the age of 76. He was the earliest assistant of Rudolf Virchow in Berlin, was then appointed as regular professor at Königsberg and six months later went from there to Würzburg. From here he was transferred in 1872 to the newly founded university of Strasburg. The most important of his investigations are the discovery of the wandering connective tissue cells and the establishment of the functions of lymph vessels. Of his monographs his "Handbook of General Pathology, Circulation and Nutrition" is worthy of special mention.

The Cholera

As was to be expected the cholera has also reached us. August 26 a man and wife in our neighboring city, Spandau, sickened of cholera and the woman died the next day. The source of this infection has not yet been determined. Other cases have not yet occurred; the suspicion of cholera in several cases of vomiting and diarrhea was not sustained. August 27 the department of education in conjunction with representatives of the imperial and Prussian provincial authorities adopted further measures for the prevention of an invasion of cholera. In view of the increasing spread of cholera in Russia, the passengers coming by vessels and rafts from Russia have not only been inspected by physicians but their excretions have been bacteriologically examined for the presence of cholera. In this way it was possible to arrest three persons on the Vistula river who seemed perfectly healthy but nevertheless harbored cholera germs in their intestinal contents that might easily cause contamination of a stream by their excretions. These persons were immediately removed and placed under observation. For more careful supervision of commerce along this river as it emerges from Russia into German territory, the establishment of a supervising station at Thorn has been ordered in addition to those already established at Schillno, Schulitz and Einlage. The Russian raftsmen discharged at Thorn are returned by the railroad to Alexandrowo just over the border in Russia. Necessary measures have also been taken against the danger of an invasion of cholera from Italy or Austria. As was to be assumed, the cholera was imported to Italy from the Black Sea. In Russia up to August 19, about 115,000 were attacked, of whom 50,000 died. According to the statement of a Russian journal, thousands of localities are affected. As usual the people oppose the orders of the physicians and the authorities and recognize only brandy as the single remedy for cholera.

Personal

Professor Gaffky, director of the Berlin institute for infectious diseases, has been appointed a regular honorary professor. —Professor Payr, of Greifswald, has declined the call to Zurich as successor to Krönlein. —Professor Perthes, of Leipzig, has been appointed successor to Professor von Bruns, of Tübingen. —Professor Schwartz, the distinguished otologist of Halle, died August 22, at the age of 72. He has been director of the ear clinic in that place since 1884. The most important of his numerous works are "Pathologic Anatomy of the Ear," in the unfinished "Handbook of Pathologic Anatomy" by Klebs, the "Text-book of Surgical Diseases of the Ear," the fiftieth number of "Deutsche Chirurgie" and the "Handbook of Ear Diseases." For a long time he was editor of the *Archiv für Ohrenheilkunde*.

Disbursements for Wage-Earners' Insurance

In 1909 the German Empire, according to the recently published report, expended \$12,500,000 (51,500,000 marks) for disability and old age insurance, \$250,000 (1,000,000 marks) more than in the previous year.

Quackery in Prussia

According to a report published by the department of education, the number of quacks inscribed in the lists of the official physicians in the year 1908 was 7,549. The number has constantly risen in recent years. The proportion of quacks to the number of physicians and dentists in the same year was 36.29 per cent., while in the previous year it was 32.72. In spite of the care of the officials to enlighten the public and in spite of the judicial punishment of quacks for fraud and physical injury, even with fatal results, the activity of the quacks is scarcely diminished. For this reason the government is contemplating again the introduction into the Reichstag of a bill for a German law against quackery. Meanwhile it is being discussed by the upper house.

Nursing Premiums

Especially good results are reported from a district of Württemberg from the introduction of nursing premiums. In that district the infant mortality in the country is very remarkable; in one community in late years on the average about 30 per cent. of the children died in the first year of life. After a philanthropic society offered a daily premium of from 25 to 50 pfennigs (6 to 12 cents) for all needy mothers who nurse their children after the first six weeks, more than two-thirds of the children were nursed during the first 3 months, and only 3 died, while of the rest who were artificially fed during the same time, 26 died.

Instruction in Biology in the Higher Schools

As a result of repeated efforts by a committee appointed at the German Naturforscher annual meeting, biologic instruction was introduced a few years ago into the higher schools, gymnasia, etc. Especially exercises in natural science have been more and more introduced and have given good results. The Prussian minister of education has for that reason made an announcement in which he holds it very desirable to continue these exercises because great value must be attributed to practical methods of instruction for stimulating observation and independent thought as well as for a recognition of the peculiar importance and limited applicability of scientific methods of work. The instruction consists of laboratory exercises in chemistry, instruction in natural history, observation in the school garden, terrariums and aquariums, experiments in plant physiology and exercises in simple macroscopic and microscopic preparations. Schools which are unable to provide for such exercises from their own means are assured aid from the department.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, August 29, 1910.

Sporadic Cholera in Vienna

As pointed out in the last Vienna letter, the spread of cholera toward central Europe has been energetically combated. Only two cases have appeared in this city: one patient died, the other survived. Isolation and disinfection, promptly applied, proved efficient, and these two cases remain as yet the only ones reported. Wide publicity has been given to the fact that the disease has found its way into the heart of the empire. But the Board of Public Health thought it wisest to let the people know the actual conditions, so as to justify the very strict measures and restrictions of commerce which modern hygiene and prophylaxis require. In Hungary, too, sporadic cases have been reported, but here also, the authorities have succeeded so far in stamping out any extension of the infection.

University Students in Austria

Statistical data are now available about the students inscribed at the Austrian universities during the summer term, 1910. Altogether there are eight universities in this country, with a little less than 25,000 students, or an increase of 8 per cent. over the figures of 1909. Ninety-two per cent. were men, 8 per cent. women. The medical students numbered 4,098, an increase of 14 per cent. when compared with last year's figures; while nearly 11,000, or 47 per cent. of all, studied jurisprudence, the increase in the latter group being only 8 per cent. The medical course was taken up by only 16 per cent. of the total. This is explained by the necessity of producing a diploma of jurisprudence for appointment in the civil service. Two hundred and twenty-one women, constituting 5 per cent. of the total number of medical students, took up medicine. As the number of female students was

altogether 1,950, this means that over 11 per cent. of all women studying at the universities want to become doctors of medicine. There is a decrease, both relative and absolute, of the number of female medical students, and an increase of male medical students. The reasons are as yet obscure, for the expectations and openings for female practitioners are rather more numerous and better than before. More puzzling still is the increase in numbers of men taking up medicine. In spite of the warnings to the graduates of colleges and gymnasiums, the admonitions of medical associations, the explanations published often in the dailies as to the hardships and difficulties of a general practitioner, the output of doctors is still increasing. In Vienna alone, last year, there were 1,813 students in hospitals, laboratories and clinics, while the remaining seven universities each had between 300 and 500 medical students to provide for. The teaching is uniform all over the empire as far as possible. Therefore, there is no distinction whatever made between diplomas gained at any of our seats of learning. On the contrary, students are encouraged to frequent as many universities as possible, preferably those of their own language. The age at entrance to university has been fixed at 18 years, but there were seventy-two persons younger than that, while there is no upper age limit. The final medical examinations, however, must be passed within seven years after the first examination to be regarded as valid. The oldest medical students were a man of 64, a retired judge, and a man of 60, who thus prepares himself for his arduous career as a missionary.

The attempt has been made to obtain reliable figures showing how many students were non-consumers of alcohol, and also as regards the general health. In Vienna it was found that not only pulmonary troubles, but also genital diseases, especially gonorrhea, were not infrequent. Exact figures will be forthcoming shortly.

Discontinuation of Weak Diphtheria Antitoxin

The results obtained in treatment of diphtheria with antitoxin are still not recognized uniformly, but it is the opinion of the majority of doctors that only strong doses are really useful. Therefore, the ministry of the interior has ordered the serotherapeutic institute in Vienna (the only authorized serum factory here) to discontinue the production of serum containing less than 1,000 units. This has been received with great satisfaction by practitioners.

The Health of Austria

Every three months a report is issued by the board of health on the health conditions in the empire. Thus for the spring of 1910, it appears that we have had exceptionally favorable conditions. With the exception of diphtheria (with 11 per cent. mortality) and typhoid (7 per cent. mortality) all infectious diseases have diminished in severity and frequency. Especially measles, cerebrospinal meningitis, scarlet fever and poliomyelitis have gone down; smallpox was reported only in ten cases altogether. Anthrax (eleven cases with three deaths) appeared sporadically. In every instance the infection was traced to occupation with hides and hair. Altogether there is constant decline in morbidity since the spring of 1909, in spite of the very changeable weather prevailing in Central Europe.

Miscellany

Parasitic Culture.—That the general culture ideal that certain courses of physical or mental discipline will give a fund of physical or mental energy potentially available for all the demands of subsequent life, may be a mistaken one, is a proposition advanced by George E. Dawson, Ph.D. (*Pop. Sc. Monthly*, September, 1910). The term "general culture" as applied to the organic life is probably a misnomer. The culture we get from gymnastic training and from the athletic field is really special in character and is applicable mainly or solely to the types of physical activity that constitute the training, and unless organs continue to perform the functions for which they were trained they become useless and a detriment to life. They become parasitic. The same proposition holds true with regard to the brain and the intellect, and applies to the unused organs of the mind that have been trained through stunts in mathematics and the classical languages, though the evidence may seem less tangible and

conclusive. Functionless physical structures derived through artificial exercises of any kind thus fall under the general biologic law of atrophy with all its attendant consequences of waste and disease. The only really economical form of physical culture, biologically speaking, is the culture derived through performing activities associated with the natural, fundamental and long-established functions of life. These are, in general, the spontaneous play-activities of childhood and the productive work-activities of manhood, each performed under normal conditions of stimulus and environment. Dawson quotes Payot, who says that the qualities of vital resistance are in no way dependent on muscular strength. A man may be an athlete in a circus and yet have very poor health, while a man who lives in his study may have an iron constitution with mediocre muscular power. Applying this to mental culture, Dawson lays down the proposition that the intellectual culture derived through standardized branches of education, as mathematics and Latin, for example, instead of having a general mental economy for those who study them, in reality becomes parasitic in the nervous and mental life, and thus a cause of wasted energy and possibly of disease. This has been proved by the test of exact experiments by psychologists, and neurology supplies additional indirect evidence. The study of the development of the cortical neurones and association fibers makes it probable that every mental process modifies these nervous elements. Thus the study of mathematics means, on the neurologic side, the building up of neurons that constitute a mathematical nervous mechanism, and the study of Latin or Greek means the building up of nervous structures specifically adapted for those languages, and those nervous organs when unused become parasitic on the nervous vitality, just as the unused muscles of the athlete become parasitic on the general organic vitality. Dawson therefore summarizes his conclusions as follows: 1. It is a law of the biologic world that unused organs become parasitic and tend toward disease. 2. Physical culture which leads to the hypertrophy of special muscles entails a drain on general vitality. 3. Experimental psychology shows that culture of particular intellectual organs and functions cannot be transferred to other organs and functions, except where there are elements in common. The histology and pathology of the nervous system confirm these conclusions. 4. Intellectual culture, not being transferable, must become parasitic and a cause of mental disorganization when it fails of application in the form or channel in which it is acquired. Illustrations are found in the overrefinements of culture in academic communities, in the nervous instability frequently encountered among educated men and women, and in the religious and social vagaries and perversions that crop out in the older and more highly cultivated centers of population. 5. This artificial culture is likely to develop a cultured proletariat, ill-balanced and inefficient as individuals, and a source of danger in our civilization.

Pharmacologic Fetishisms; Another Challenge to the Iconoclast.—The *Journal-Record of Medicine* (Atlanta) protests in its August number as follows: Barton (THE JOURNAL A. M. A., July 23, 1910) makes an attack on a number of well-known drugs, such as calomel, aconite, ammonium chlorid, sweet spirits of niter, veratrum viride, etc. The matter seems to have been considered exclusively from the standpoint of animal experimentation or at least one would judge so from the nihilistic views expressed. So at variance are Barton's ideas with those of thousands of practitioners who are daily using these remedies, that a protest hardly seems necessary. Whether calomel acts as a cholagogue or as an intestinal antiseptic matters not at all to the patient with intestinal auto-intoxication or the so-called biliousness. Incontestable facts have proved calomel to be the best remedy to make the patient well under such circumstances, so why "split hairs" and bewilder the physician who already has few enough of drugs with physiologic effects that may be relied on? Have we not all seen the diuretic effect of sweet spirits of niter? Are there sufficient millions of animals to prove it has no such action in human beings who are being treated with it? Spartein is maligned as being a worthless cardiac stimulant, but not a word said of its value as a renal stimu-

lant; given hypodermically in 1 to 2 grain doses, the writer knows of no more dependable drug when suppression of the urine is feared—especially if it be given early, for instance, twelve hours before an operation where suppression is a danger. It is not to fight the individual battles of these separate drugs that this editorial is written, but rather is it intended to condemn the indiscriminate nihilism underlying the above article. For the sake of hyper-scientific accuracy, Barton marshals before us an array of petty points of weakness of our most valuable drugs, and thus he weakens our faith in our best and most reliable friends and makes us all the easier prey to the alleged virtues of many worthless proprietary preparations so scientifically (?) heralded before us. If we are not to use these drugs which are condemned, in part if not totally, then what should we use in their stead? Can Barton provide for us more reliable drugs than those he declares so worthless?

The Etiology and Biology of Tumors.—The present communication is the last of a series of ten articles dealing with the etiology and biology of tumors of different types. In it E. Saul (*Centralbl. f. Bakteriologie, Parasitenk. u. Infektionskr., Orig.*, 1909, lii, 235) gives a summary of the principal results obtained from a long series of experiments and observations. He finds that in fibromas, cystomas, carcinomas and sarcomas, a special class of parasitic organisms exist. These same organisms may occur extracellularly, either as ameboid or encysted forms, or intracellularly, when they appear as granules or vacuoles. The ameboid and encysted forms are destroyed by fixation and imbedding. Protozoa, says Saul, which give rise to chronic infections, may, under the influence of the living organism, acquire such developmental forms that it is impossible to demonstrate them within the tissues. There are parasitic protozoa, which are infectious in the ameboid stage only, which infiltrate embryonic cells only and which appear as granules or vacuoles in the cells thus infiltrated. By inoculating the ordinary experimental animals with a certain type of cancer parasite, Saul asserts that it is possible to bring about in these animals acute fatal intoxication, granulation tumors, interstitial lymphatic and connective-tissue proliferation in the kidney and the lung (which present the typical picture of chronic interstitial nephritis and fibrous peribronchitis) and cachexia which takes the form of extreme emaciation, ending with death. As in the case of tuberculosis, carcinoma shows a tendency to follow certain chosen paths. Regarding metastases, it is believed that carcinoma fluid is avirulent in the blood-stream, while sarcoma fluid is avirulent in the lymph-stream. From subcutaneous implantation of parts of *Cysticercus fasciolaris* either acute fatal intoxication resulted in the experimental animals or neoplasms developed, which were on the boundary zone of fibroma, sarcoma and granulation tumors.

The Rôle of Streptococci in Scarlet-Fever Infections.—F. Schleissner finds (*Folia Serologica*, 1909, iii, 221) that the blood of scarlet-fever patients always contains antibodies for streptococci. By the method of complement-fixation he attempted to determine whatever etiologic significance streptococci possess in scarlet-fever infections. Various strains of streptococci from the blood of scarlet-fever patients were cultivated and emulsions of these strains were used, according to the method of Bordet-Gengou, with a series of scarlet-fever cases for the fixation of the complement. Two sets of controls were also employed; on the one hand, serum from various classes of diseases which were not in any way connected with streptococcus infection, and on the other hand, streptococcus strains from erysipelas, sepsis puerperalis and panophthalmia. In the majority of cases of scarlet fever (2 to 5 weeks), the serum gave a positive reaction with scarlet fever streptococcus cultures. With streptococci from erysipelas the reaction was always negative, while with other streptococci there was usually a retarding of hemolysis. From his experiments Schleissner concludes that the constant occurrence of antibodies in the blood of scarlet-fever patients indicates that streptococci stand in some biological relationship to the disease processes in scarlet fever. This relationship, however, is at present, so obscure that it furnishes no certain proof that streptococci have a definite etiologic significance in the disease.

Deaths

James Nevins Hyde, M.D. University of Pennsylvania, Philadelphia, 1869; a member of the American Medical Association; twice president of the Chicago Dermatological Association; second president of the American Dermatological Association; and an honorary, active or corresponding member of the leading dermatologic associations of Europe; assistant surgeon in the Navy for two years during the Civil War and for three years thereafter; for thirty-one years professor of skin, venereal and genito-urinary diseases in Rush Medical College and secretary of the council administration and faculty of the institution; professorial lecturer on dermatology at the University of Chicago since 1902; a notable contributor to the literature of dermatology; and the author of a standard text-book which is already in its eighth edition; dermatologist to the Presbyterian, Augustana and Michael Reese hospitals, and the Chicago Orphan Asylum; a member of the Mayflower Society, the Society of Colonial Wars, and the Sons of the American Revolution; one of the most prominent specialists on skin and venereal diseases of America; died suddenly September 6, at his summer home, Prout's Neck, Maine, aged 70.

Dr. Hyde was one of the best known of American medical men. Not only was he highly regarded by his coworkers in his chosen field of professional work on account of that work, but because of his interest in medical affairs and the medical profession generally. All who knew him loved him for his liberality and for his kindness toward all who approached him, young men especially.

William Bailey Sanford, M.D. University of Nashville, Tenn., 1880; of Memphis; a member of the Tennessee State Medical Association; for ten years health officer of Alcorn county, Miss.; surgeon to the Memphis and Charleston Railroad; vice-president of the Mississippi Medical Association, and surgeon and chief of the North Mississippi Medical and Surgical Infirmary; professor of medical economics and life insurance in the College of Physicians and Surgeons, Memphis; died in Colorado Springs, September 2, from erysipelas, aged 59.

David D. Bramble, M.D. Medical College of Ohio, Cincinnati, 1862; a member of the Ohio State Medical Association and Cincinnati Academy of Medicine; for many years professor of surgery and dean of the Cincinnati College of Medicine and Surgery; health officer of the city in 1883 and 1884; died at his home in Avondale, September 2, from nephritis, aged 70.

Frank Fleury, (years of practice, Ill., 1887); of Springfield; from 1881 to 1885 secretary of the State Board of Pharmacy; secretary of the Illinois State Pharmaceutical Association in 1880; died at the home of his daughter in Springfield, August 29, from uremia, aged 68.

Emily Blackwell, M.D. Western Reserve University, Cleveland, 1854; of Montclair, N. J.; who with her sister, the late Dr. Elizabeth Blackwell, founded the New York Infirmary for Women and Children, the first hospital for women in America; died at her summer home in York Cliffs, Maine, September 8, aged 84.

Otto Clarence Baird, M.D. University of Iowa, Iowa City, 1910; of Lockridge, Iowa; while attempting to board a moving train at that place, August 19, was thrown under the wheels and had both legs cut off just above the ankle, and died in the Burlington (Iowa) Hospital, August 21, aged 24.

JAMES NEVINS HYDE. 1840-1910

Parley Howard Eaton, M.D. Howard University, Washington, D. C., 1881; chief of the Division of Issue, Treasury Department, Washington, D. C.; died in Georgetown University Hospital, Washington, February 12, thirty-six hours after an operation for ulcer of the stomach, aged 67.

Joseph Theodore Green, M.D. Kentucky School of Medicine, Louisville, 1893; a member of the American Medical Association; local pension examining surgeon and surgeon of the Illinois Central Railway; died in St. Anthony's Hospital, Louisville, August 30, from pneumonia, aged 43.

Alfred Hamilton Iddings, M.D. Bellevue Medical College, 1866; for several terms health officer of Dayton, Ohio, and for two terms a member of the board of education; local United States pension examiner; died at his home August 20, from chronic interstitial nephritis, aged 70.

Harry Vroom Day, M.D. New York University, New York City, 1877; a member of the American Medical Association; president of the Borough council of Butler, N. J., and vice-president of the First National Bank; died at his home in Butler, August 30, from cancer, aged 58.

George F. Perry, M.D. Washington University, St. Louis, 1875; of Ochiltree; a member of the State Medical Association of Texas; in 1890, representative in the state legislature; died in St. Francis Hospital, Colorado Springs, August 30, from uremia, aged 63.

Ernest Douglas Powell, M.D. Vanderbilt University, Nashville, 1900; one of the inspectors of public schools of Memphis, Tenn.; died in his office from the effects of a gunshot wound of the head believed to have been self-inflicted while despondent, aged 36.

Edmund Livingstone Moodie, M.D. Baltimore Medical College, 1902; of Chatham, Ohio; a member of the American Medical Association; died in St. Louis, July 8, from sepsis, following an operation for hemorrhoids, aged 36.

William J. W. Cornwell, M.D. Medical College of the State of South Carolina, Charleston, 1866; a member of the South Carolina Medical Association, and a Confederate veteran; died at his home in Cornwell, July 16, from gastritis, aged 69.

T. Frank Keys, M.D. University of Pennsylvania, Philadelphia, 1883; died at his home in Chicago, September 6, from inanition following operations necessitated by pyloric stenosis of long standing, aged 50.

Chancellor Yager, M.D. Kentucky School of Medicine, 1877; a member of the Kentucky State Medical Association; died at his home in Shelbyville, September 4, from typhoid fever, aged 53.

George Barstow Richmond, M.D. New York University, New York City, 1879; formerly of Salinas, Cal.; died at his home in Westboro, Mass., July 31, from pulmonary hemorrhage, aged 52.

Harold Lee Barnum, M.D. Hahnemann Medical College of Philadelphia, 1902; city physician of Sedalia, Mo., for two years; died at his home, August 30, from cerebral hemorrhage, aged 35.

Umberto Buffo, M.D. University of Turin, Italy, 1904; a member of the American Medical Association; of McAlester, Okla.; died in New York City, August 31, from nephritis, aged 31.

Tobie Lucien Lougarre, M.D. Tulane University, New Orleans, 1876; a member of the Louisiana State Medical Society; died at his home in Moreauville, August 29, aged 72.

Charles T. Buckholtz, M.D. Homeopathic Medical College of Missouri, St. Louis, 1874; died at his home near Murphysboro, Ill., August 30, from angina pectoris, aged 69.

Harry Hunter Fox, M.D. Southern Homeopathic Medical College, Baltimore, 1904; died at his home in Baltimore, August 29, from nervous breakdown, aged 30.

John Allan Batton, M.D. Jefferson Medical College, 1882; a member of the American Medical Association; died at his home in Uniontown, Pa., March 14, aged 53.

Samuel C. Johnson, M.D. Jefferson Medical College, 1879; of Sharon, Pa., died from angina pectoris while sitting at the bedside of a patient, August 28, aged 57.

John Wilson, M.R.C.S. England, 1858; of Detroit; died at the home of his son in St. Joseph, Mich., August 19, from myocarditis, aged 71.

Harrison McFadden, M.D. Medical College of Ohio, Cincinnati, 1862; died at his home in Magnetic Springs, Ohio, August 31, aged 70.

Jane Howarth Bowker, M.D. Tufts Medical College, Boston, 1896; died at her home in Cambridge, Mass., August 5, from paralysis, aged 69.

Marshall Job Brown, M.D. University of Maryland, Baltimore, 1907; died in Baltimore, September 4, from acute gastritis, aged 27.

Marion D. Ditzler, M.D. Cincinnati College of Medicine and Surgery, 1876; died at his home in Lewistown, Ohio, August 31, aged 56.

Jennie E. Barrows, M.D. Eclectic Medical College of the city of New York, 1872; died at her home in Berkeley, Cal., August 27.

Henry B. Arnold, M.D. Jefferson Medical College; died at his home in California, Pa., January 5, from senile debility, aged 83.

Melvin Rhorer, M.D. University of Louisville, 1871; died at his home in Lexington, September 5, from tuberculosis, aged 68.

James Monroe Carver, (license. Ind., 1897); died at his home in Winchester, March 16, from chronic nephritis, aged 55.

Marriages

H. A. BORN, M.D., to Miss Elizabeth T. Blankner, at Baltimore, August 31.

MILO GOSS SLOO, M.D., Topeka, Kan., to Miss Louise Fuerst of Chicago, August 27.

JOHN R. BUSER, M.D., Delavan, Minn., to Miss Alma Rosine Arnold of St. Louis, Mo., September 1.

HENRY NEILL WHITELOW, M.D., Oakesdale, Wash., to Miss Mary Macklin of Pasadena, Cal., September 7.

SAMUEL STUART HACKWELL, M.D., Blaney, Mich., to Miss Jean Beulah MacTaggart of Bad Axe, Mich., August 31.

THEODORE GAWN FINLEY, M.D., Los Angeles, Cal., to Miss Bertha Madelaine Vilas of Berkeley, Cal., September 1.

HARRY PIDDOCK KNOWLES, M.D., South Haven, Kan., to Miss Eleanor Malinda Porter of Sterling, Kan., September 1.

JOHN WALKER CARTER JONES, M.D., Newport News, Va., to Miss Charlotte Wilson Stephenson of Warm Springs, Va., August 31.

CHARLES KNICKERBOCKER WINNE, JR., M.D., Albany, N. Y., to Miss Sarah Foster Merrill of Baltimore, at New York City, September 1.

Japanese Medical Archives.—The first number of the ninth volume of the archives published in the German language by the medical department of the Tokyo University maintains the high standard of the preceding volumes. It is a work of 174 pages, and contains also the total list of contents from the inception of the *Mitteilungen*. The leading article is on the pathologic anatomy of the nerves and muscles in beriberi, with fine illustrations and tabulation of the findings compared with those of fourteen other workers in this line at home and abroad.

Pharmacology

KEPHALOSE

A French Headache Remedy That Has Been Declared Misbranded

The following communication from Dr. J. R. Hurley, a district health officer at Iloilo, P. I., throws an interesting light on the "patent medicine" business in the Philippine Islands:

"I believe that you are keeping a record of the prosecutions and judgments obtained under the Food and Drugs act. I don't know whether you are interested in such matters in the Philippines or not, but I am reporting the following case for your information. The case was brought against the firm known as 'The Estrella del Norte' doing a general retail business, and which imports and distributes a French proprietary remedy known as 'Kephalse.' All sorts of impossible claims are advertised for this nostrum, including those for which acetanilid is recognized as being useful when intelligently prescribed by a physician. In fact it was the intention of the manufacturers and exploiters to introduce this nostrum in this country as a common household remedy.

"The nostrum was advertised as being harmless, and rules for dosage were contained in a circular which goes with each box, also setting forth the manifold ailments in which it is a 'sure cure.'

"Apparently to comply with the customs regulations, on a small yellow label on the box it states that each dose (one tablet) contains 2 grs. of acetanilid. Inasmuch as it was obviously to be sold broadcast to the native Filipinos, a small proportion of whom can read English at all, much less know what acetanilid is, and on account of the well-known toxic effects of acetanilid, unless prescribed intelligently and with discretion where it is indicated by a physician, it was decided to prosecute the distributing firm under two counts.

"To prove that the nostrum was misbranded, and that the company was selling dangerous drugs without a pharmacist's license, samples were bought in the open market, and, properly labeled, sent to the Bureau of Science, Manila, for analysis. The analysis showed Kephalse to be composed of the following:

Moisture	5.0
Antipyrin and caffeine.....	75.9
Acetanilid	trace
Potassium bromid	3.8
Sodium carbonate	3.3
Sugar	12.0
	100.0

Colored with an anilin dye.

"This fact was brought forward at the trial, together with such other evidence necessary to show that the nostrum contained a dangerous drug, and could not be considered as a household remedy, which proved that the nostrum was misbranded, and that the company was therein selling a dangerous drug, without a physician's prescription, and without a licensed druggist to put it up.

"The court found the Estrella del Norte guilty, and fined the company fifty pesos, an amount equal to twenty-five dollars, gold."

COMMENT.—Dr. Hurley's letter goes to show that the American government safeguards the health of the Filipinos more jealously than it does that of the native American. If the manufacturers of the thousand-and-one acetanilid or antipyrin-containing nostrums sold to the laity in this country should be fined for selling a dangerous drug as a household remedy what a howl of protest would go up. Doubtless Dr. U. S. Boone, of St. Louis, the Antikamnia people or the Proprietary Association of America would at once set to work collecting "statistics" to prove the innocuousness of antipyrin and acetanilid.

Association News

DATE OF NEXT SESSION

Suggestions Desired by Board of Trustees Concerning Los Angeles Session, 1911

The date of the next session of the American Medical Association, to be held in Los Angeles, California, is a matter of considerable importance. The great distance which a majority of those who attend will be obliged to travel, and the length of time necessarily consumed in the journey, make it more essential than usual that the date be the one which shall accommodate the greatest number of those who desire to attend. That several of the members are already taking an interest in the matter is evidenced by a number of letters on the subject which the Chairman of the Board of Trustees has received recently and he takes this opportunity not only to acknowledge their receipt but also to express his thanks to the writers thereof for their views thus presented.

It seems to be generally recognized that the first week in June is not a desirable time for the session for the reason that it conflicts with the examinations and the commencement exercises of a large majority of the medical colleges throughout the country.

The question, then, is whether the session should be held early enough in May or April to permit those living in the east to attend and to return in time to close up their college work for the year, or late in June after the college work is over.

If held during the college term it means that many who desire to attend will be unable to do so, perhaps, and that others will be obliged to make a flying trip, while in favor of a later date it may be said that we shall probably secure very favorable railroad rates, with long time extension and choice of diverse route returning with liberal stop-over privileges. This will enable those who so desire to spend their summer vacations in the west or northwest where there are many beautiful and interesting places to visit.

It has been suggested by some that the weather in Los Angeles late in June might be uncomfortably hot. In order to have some reliable information on the subject, the Chairman of the Board of Trustees has secured, from the director of the government weather bureau at Los Angeles, extensive data concerning the weather—temperature, humidity, winds, etc.—at that point for several years past. The following extracts from a letter received from A. B. Wollaber, local forecaster at Los Angeles, indicate very well what may be expected in the line of weather:

"I take pleasure in stating that a careful examination of the records of this office covering a period of 33 years shows that the temperature conditions here are very equable and, with the exception of an occasional warm spell that might occur at any time throughout the year, not at all unpleasant. The highest minimum temperature on record for May is 70 degrees, the average minimum being 52 degrees. For June the highest minimum on record is 70 degrees, the average minimum is 56 degrees and for July the highest minimum is 76 degrees, average minimum 59 degrees. The minimum temperature may be said to fairly represent the night temperature. The average maximum or day temperature during May is 73 degrees, June 78 degrees and July 82 degrees.

"There is one important factor in our temperature conditions here in Los Angeles not easily shown by figures. I refer to the comparatively short duration of the extremes of both heat and cold. It is very rare for the temperature to stay at a maximum for over two hours at a time and the maximum, as a rule, occurs shortly before or shortly after noon. The temperature rises gradually with the advance of the day, until it reaches the maximum when, under the influence of the daily ocean breeze it drops gradually downward until it reaches the minimum during the early morning hours.

"Another and most important factor to be considered is the low humidity which always prevails during the heat of

the day. During heated terms it is not unusual for the humidity to drop as low as 6 per cent, while the average humidity during the heat of an ordinary summer day ranges between 35 and 50 per cent."

Thermograph and hydrograph trace sheets showing the actual temperature and humidity during this period were received, fully confirming the statements above mentioned. It will thus be seen that the fear of meeting with excessively hot weather, even though the session should be held as late as the last week in June or the first in July, are entirely without foundation.

In setting the date of the meeting the Board of Trustees desires solely to accommodate the greatest number and the Chairman of the Board will be very grateful if all who are interested in the date of the session will indicate to him by postal or letter the date on which it will be most convenient for them to attend.

M. L. HARRIS, Chairman, Board of Trustees.
100 State Street, Chicago.

Correspondence

Registration of Foreign Physicians

To the Editor: To elucidate further the matter of "Registration of Foreign Physicians," I beg leave to comment on the remarks of the writers of the letters in THE JOURNAL, September 3 and 10. Dr. Honeij is right; I am a Canadian, but again he is wrong. I have no friends who wish to register in the United States in the near future or at any other time. If I did have, I should not need to apologize for them, as I am sure that they would acquit themselves honorably.

He is also wrong when he says that I do injustice to American physicians. I reiterate my letter of August 27, and as I spoke truthfully, wherein lieth the injustice? I am sure that the American physician (and not every practitioner is a physician) would rightly resent being classed among the ill-trained aspirants for license to practice in Canada or elsewhere who admit their inability to qualify. That the best colleges of the United States are all I will not deny, but that the graduates from the best colleges find the expressed difficulty in obtaining license to practice in Canada, I question. I could easily qualify the remarks as to the thoroughness of the various state board examinations, but I will pass them over, only saying that they are relatively hard, i. e. comparing one state with another. I do not know the requirements of all foreign countries. I was talking about Canada.

A word about the requirements of Great Britain. The conjoint and other boards require a statement of the time spent in each subject, with an examination in that subject in which the candidate passed successfully, certified to by the professor of the subject, before he is permitted to take the examination. The medical council in London accepts the proper credentials from the best American schools, but not from "diploma mills." The examination is both oral and written.

The only reason I can put forth for Dr. Honeij being referred to the Nova Scotia school is that, poor as is its standing, it came nearer the standard required by the licensing board than did the school from which he graduated. I knew several graduates of American universities when I was in London and these had no difficulty in qualifying for and passing the examination. The fact that Dr. Honeij was a citizen of South Africa is no reason why less should be required of him in order to practice medicine there. I would rather suggest raising the standard of examination, requirements, etc., as a means toward keeping foreign physicians out, than by making appeals for legislation whereby the public must suffer. Possibly in the future the foreign countries in question will lower their standards and then the poorly informed "Doc." will be able to shake hands with his friend from abroad and feel himself an equal.

D. NATHAN, Norristown, Pa.

Fleming Test in Serodiagnosis of Syphilis

To the Editor:—A communication from Dr. Bernard Oettinger calls my attention to an omission in my article on serum diagnosis of syphilis (THE JOURNAL, August 27, 1910) I quoted Bassett-Smith as having found the Fleming modification unsatisfactory. In a later communication Bassett-Smith revises his previous opinion of the Fleming test as the result of further experience (Brit. Med. Jour., 1910, March 12, p. 632). From a series of 500 cases his results were indefinite in only 10 per cent. "A positive result was always reliable, in fact it was obtained in some cases earlier in the disease than with the other methods tried."

HOWARD FOX, New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DATA WANTED ON POSTOPERATIVE TETANY

Dr Francis D. Patterson, 2103 Locust St., Philadelphia, is anxious to secure the details of any hitherto unreported cases of postoperative tetany.

PRAIRIE ITCH

To the Editor:—What is the medical term for what is known in the northwest as "prairie itch"? J. F. KENNEDY, New York

ANSWER:—"Prairie itch" is a term applied in the west and northwest to a number of forms of pruritus, the most frequent of which is a pruritus described under the name of pruritus hiemalis. Similar conditions exist in various parts of the country among farmers, lumbermen, miners and others and are variously called "Texas mange," "Ohio scratches," "swamp itch," "lumberman's itch," etc. Many cases of so-called "prairie itch" are undoubtedly scabies.

PALATABLE COUGH MIXTURES

To the Editor:—I do not like the idea of having to use "patent medicines," consequently I would like to know of a cough mixture that is serviceable and palatable, and also a good anodyne liniment which is not obnoxious to the patient. E. J. G. S.

ANSWER:—The Physicians' Manual of the Pharmacopeia and the National Formulary refers to thirteen official cough mixtures, a sufficient variety from which to select one suitable to almost any case, so that there seems no need of resorting to nostrums. They are:

Elixir plicis compositum	Syrupus chondri compositus
Elixir terpinii hydratis	Syrupus pectoralis
Mistura glycyrrhizæ composita	Syrupus pini strobi compositus
Mistura ammonii chloridi	Syrupus scillæ compositus
Mistura olei plicis	Trochisci ammonii chloridi
Mistura pectoralis	Trochisci glycyrrhizæ et opii
Species pectoralis	

The following anodyne liniments may be used singly or in mixtures:

- Linimentum belladonnæ, N. F.
- Linimentum camphoræ, N. F.
- Linimentum opii compositum, N. F.

TECHNIC OF ELABORATING AUTOGENOUS VACCINES

To the Editor:—Please give me the detailed technic of elaborating autogenous vaccines. After pure culture is obtained, how are the germs killed, counted and put up in the sealed tubes? J. S. WEBER, Davenport, Iowa.

ANSWER:—The bacteria are killed by exposure to a temperature of 60 C. for an hour. They may be counted by Wright's method which is as follows: Equal quantities of the culture are mixed with normal blood; after staining a preparation on a slide, the ratio of bacteria to the red blood cells is determined by counting. Since there are about 5,000,000 red blood cells to the cubic millimeter in normal blood, the number of bacteria is easily calculated from the ratio which has been found. The culture may now be diluted so as to contain the requisite number of bacteria per cubic centimeter and placed in a sterile container which may be hermetically sealed in the frame, if desirable.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Sept. 10, 1910.

Stallman, Geo. E., D.S., Aug. 27, returned to Ft. Sam Houston, Texas, from Leon Springs, Texas.

Harris, H. S. T., lieutenant, Aug. 23, ordered to proceed from San Francisco, to Camp of Instruction, Atascadero, Cal., for duty.

Bevans, James L., capt., Aug. 30, ordered to proceed from San Francisco with one-half of Co. B Hospital Corps, to the Camp of Instructions at Atascadero, Cal., for duty.

Clarke, Jos. T., maj., and Fisk, Owen C., lieutenant, Aug. 25, ordered to proceed with the troops from Ft. Crook, Neb., to the fair grounds, Des Moines, Iowa, for duty during the military tournament at that city. Sept. 26 to Oct. 1, 1910.

Rand, I. W., maj., September 3, left Fort Hancock, New Jersey, on ten days leave of absence.

Bourke, James, capt., August 25, order to proceed with troops from Fort Leavenworth, Kansas, to the Des Moines Military Tournament, etc.

Murtaugh, John A., maj.; Van Dusen, James W., capt.; and Fuller, Leigh, maj.; August 25, ordered to proceed with troops from Fort Riley, Kansas, to the Des Moines Military Tournament, etc.

Barney, Charles N., maj., September 6, left Fort Wadsworth, N. Y., enroute home awaiting retirement, being granted leave of absence to December 31, 1910.

Grubbs, Robert B., maj., September 1, reported on detached duty at Fort Sam Houston, Texas, from Camp at Leon Springs, Texas.

Hallett, Harley J., M.R.C., September 6, granted 30 days leave of absence terminating not later than November 3, 1910.

Baker, Charles L., M.R.C., September 2, now on duty in Sequoia, and the General Grant National Parks, will accompany Troop A, 1st Cavalry to the Presidio of San Francisco, and on arrival will report to the commanding officer of that post for duty.

Reynolds, Royal, lieutenant, Sept. 7, ordered to Presidio of San Francisco, for temporary duty.

Allen, John H., maj., Sept. 7, left Fort Myer, Virginia, on ten days leave of absence.

Walker, Thomas C., M.R.C., September 7, granted leave of absence for two months to take effect on arrival in the United States.

Canaday, George H., D.S., September 3, left from duty at Fort Baker, California, enroute to the Philippine Islands, for duty.

Medical Corps, U. S. Navy

Changes for the week ended Sept. 3, 1910:

Fitts, H. B., medical inspector, placed on the retired list from Aug. 23, 1910.

Grove, W. B., surgeon, detached from the Naval Training Station, Newport, R. I., and ordered to duty at the Naval Medical School Hospital, Washington, D. C.

Leys, J. F., surgeon, detached from temporary duty in the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Training Station, Newport, R. I.

Cather, D. C., P. A. surgeon, detached from the Naval Academy and ordered to the Iowa.

Pryor, J. C., surgeon, detached from the Navy Yard, Pensacola, Fla., and ordered to the Bureau of Medicine and Surgery, Navy Department.

Jenkins, H. E., asst.-surgeon, detached from the Franklin and ordered to the Montana.

Hermesch, H. R., asst.-surgeon, detached from the Montana and ordered to temporary recruiting duty at Knoxville, Tenn.

Thomas, G. E., asst.-surgeon, detached from the Dubuque and ordered to temporary duty at the Naval Hospital, Mare Island, Cal.

Changes for the week ended Sept. 10, 1910.

McDonnell, W. N., passed asst.-surgeon, detached from the Naval Academy and ordered to the Massachusetts.

Boyd, J. C., medical director, detached from command of the Naval Medical School, Washington, D. C., and ordered to duty as a member of the naval retiring board, navy yard, Washington, D. C.

Wise, J. C., medical director, detached from duty as a member of the naval retiring board, navy yard, Washington, D. C., and directed to wait orders.

Gatewood, J. D., medical inspector, detached from duty on board the California as fleet surgeon of the Pacific Fleet and ordered home to wait orders.

Norton, O. C., medical inspector, detached from the navy and marine recruiting stations, New York, and directed to wait orders.

Wieber, F. W. F., medical inspector, detached from the naval recruiting station, Baltimore, and ordered to duty at the naval and marine recruiting station, New York.

Lowndes, C. H. T., surgeon, detached from the naval dispensary, Naval Medical School Hospital, Washington, D. C., and ordered to the Baltimore Naval Recruiting Station.

Freeman, G. D., surgeon, detached from the Montana and ordered to duty at the naval dispensary, Naval Medical School Hospital, Washington, D. C.

Fiske, C. N., surgeon, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to duty at the Naval Medical School, Washington, D. C.

Smith, C. G., surgeon, detached from the naval hospital, Newport, R. I., and ordered to the Montana.

Cohn, I. F., passed asst.-surgeon, detached from naval hospital, Philadelphia, Pa., and ordered to the Castine.

Hull, H. F., passed asst.-surgeon, detached from the Paducah and ordered to the Panther.

Grieve, C. C., passed asst.-surgeon, detached from the navy recruiting station, Chicago, and ordered to the Prairie.

Dean, T. W. S., passed asst.-surgeon, detached from the *Prairie* and ordered to the naval magazine, Iona Island, N. Y.

Manchester, J. D., passed asst.-surgeon, detached from the *Panther* and ordered to the navy recruiting station, Chicago.

Foster, T. G., passed asst.-surgeon, detached from the naval hospital, Mare Island, Cal., and ordered to duty at the naval hospital, Cananeo, P. I.

White, E. C., passed asst.-surgeon, detached from the navy recruiting station, St. Louis, and ordered to temporary duty at the naval hospital, Mare Island.

Roland, M., asst.-surgeon, detached from the *Castine* and ordered to duty at the naval hospital, Philadelphia.

Miller, J. T., asst.-surgeon, detached from the *North Carolina* and ordered to the navy recruiting station, St. Louis.

Kelley, H. L., asst.-surgeon, detached from the naval hospital and ordered to the navy yard, Mare Island, Cal.

McMullin, J. J. A., asst.-surgeon, detached from the naval magazine, Iona Island, N. Y., and ordered to the *North Carolina*.

Bloodorn, W. A., asst.-surgeon, detached from the navy yard, Mare Island, Cal., and ordered to duty at the naval hospital, Cananeo, P. I.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended Sept. 7, 1910:

Pettus, W. J., asst.-surgeon-general, while on leave in England, directed to proceed to Southampton, Liverpool and Glasgow, on special temporary duty relative to measures for the prevention of the introduction of Asiatic cholera into the United States, and then resume leave status.

Kerr, J. W., asst.-surgeon-general, detailed to represent the Service at the annual meeting of the American Public Health Association, to be held in Milwaukee, Wis., Sept. 5-9, 1910.

Carter, H. R., surgeon, detailed to proceed to certain ports in Europe on special temporary duty relative to measures for the prevention of the introduction of Asiatic cholera into the United States.

Vasdin, Eugene, surgeon, granted 1 month's leave of absence from Aug. 22, 1910, on account of sickness.

Cobb, J. G., surgeon, directed to proceed to Manitowac, Wis., on special temporary duty. Detailed to represent the Service at the annual meeting of the American Public Health Association, to be held in Milwaukee, Wis., Sept. 5-9, 1910.

Goddines, H. D., surgeon, directed to proceed to Marseilles and Genoa, Italy, on special temporary duty relative to measures for the prevention of the introduction of Asiatic cholera into the United States, and then rejoin station at Naples, Italy.

McMullen, John, P. A., surgeon, granted 21 days' leave of absence from Sept. 3, 1910.

Anderson, John F., P. A., surgeon, granted 1 day's leave of absence from Sept. 2, 1910, under paragraph 189, Service Regulations.

Wille, C. W., P. A., surgeon, directed to proceed to Ashtabula, Ohio, on special temporary duty.

Lloyd, Bolivar J., P. A., surgeon, granted 29 days' leave of absence from Aug. 20, 1910.

Spratt, R. A., P. A., surgeon, granted 1 day's leave of absence, Aug. 27, 1910, on account of sickness.

Frost, W. H., P. A., surgeon, directed to proceed to Grundy Center, Iowa, on special temporary duty.

Mullan, E. H., P. A., surgeon, granted 5 days' leave of absence from Aug. 1, 1910, under paragraph 191, Service Regulations.

Ashford, F. A., P. A., surgeon, granted 1 month's leave of absence from Aug. 30, 1910.

Kolb, Lawrence, asst.-surgeon, granted 7 days' leave from Aug. 28, 1910, under paragraph 191, Service Regulations.

Drew, A. D., acting asst.-surgeon, granted 30 days' leave of absence from Sept. 15, 1910.

Marr, H., acting asst.-surgeon, granted 15 days' leave of absence from Sept. 5, 1910.

Moorer, M. P., acting asst.-surgeon, granted 6 days' leave of absence from Aug. 14, 1910.

O'Neill, Arthur A., acting asst.-surgeon, granted 10 days' extension of leave of absence from Aug. 9, 1910, on account of sickness.

Ransom, S. W., acting asst.-surgeon, granted 30 days' leave of absence from Sept. 1, 1910.

Schuster, B. L., acting asst.-surgeon, granted 3 days' leave of absence from Sept. 7, 1910.

Walker, T. D., acting asst.-surgeon, granted 1 day's leave of absence, Sept. 8, 1910.

Wetmore, W. O., acting asst.-surgeon, granted 3 days' leave of absence from Aug. 11, 1910, under paragraph 210, Service Regulations.

Society Proceedings

COMING MEETINGS

- Amer. Acad. of Ophthalm. and Oto-Laryn., Cincinnati, Sept. 19-21
- Amer. Asso. of Obstetricians and Gynecol., Syracuse, Sept. 20-22
- Amer. Roentgen Ray Association, Detroit, September 28—October 1
- American Association of Railway Surgeons, Chicago, October 1
- Medical Association of the Southwest, Wichita, Kan., October 19-21
- Michigan State Medical Society, Bay City, September 11-12
- Minnesota State Medical Association, Minneapolis, September 28-29
- Nevada State Medical Association, Lake Tahoe, Cal., Sept. 19-21
- Pennsylvania, Medical Society of State of, Pittsburg, October 3-6
- Utah State Medical Association, Salt Lake City, October 3-4
- Vermont State Medical Society, St. Albans, October 13-14
- Virginia, Medical Society of, Norfolk, October 25-28
- West Virginia State Medical Assn., Parkersburg, Oct. 5-7
- Wyoming State Medical Society, Casper, September 27

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirty-Eighth Annual Meeting, Held at Milwaukee, Wisconsin,
Sept. 6-9, 1910

The President, DR. CHARLES O. PROBST, Columbus, Ohio, in the Chair

Addresses of Welcome

At the general meeting of the Association, which was open to the public, addresses of welcome were delivered on behalf of the city of Milwaukee, by Hon. Emil Seidel, Mayor; on behalf of the State of Wisconsin, by Judge William J. Turner, and on behalf of the medical profession by Dr. W. A. Batchelor.

The responses to these addresses of welcome were made on behalf of the United States, by Dr. Richard Lewis, Raleigh, N. C.; on behalf of the Dominion of Canada, by Dr. Frederick Montzambert, Director General of Public Health, Ottawa, Canada; on behalf of the Republic of Mexico, by Dr. J. E. Mongarás, Mexico City, Mexico, and on behalf of the Republic of Cuba, by Dr. Frederic Torralbas, Havana, Cuba.

Officers Elected

The following officers were elected: President, Dr. Robert M. Simpson, Winnipeg, Manitoba; first vice-president, Dr. Fernando Lopez, Mexico City; second vice-president, Dr. John F. Anderson, Washington, D. C.; third vice-president, Dr. Gerhard A. Ludwig, Milwaukee, Wisconsin; secretary, Dr. William C. Woodward, Washington, D. C.; treasurer, Dr. Frank W. Wright, New Haven, Connecticut.

Havana, Cuba, was selected as the place for holding the next annual meeting.

Report of the Joint Committee on Mailing Infectious Material

DR. JOHN F. ANDERSON, Washington, D. C.: The proposed modifications of the regulations for the mailing of infectious material have finally been promulgated by the postoffice department under date of April 22, 1910. The committee believes that its efforts have resulted in the promulgation of regulations which are a decided improvement over those formerly enforced. The regulations have been considerably simplified. The committee was successful in having the privileges of the mails for the transmission of infectious material extended to include federal, state, municipal and other laboratories on the issuance of a formal permit by the Postmaster General.

The report was accepted, and the committee discharged.

Studies on Self-Purification of Streams

DR. G. F. RUEDIGER, Grand Forks, N. D., detailed a series of experiments on this subject, and then presented the following conclusions: Colon bacilli and typhoid bacilli disappear much more rapidly from polluted river water during the summer months than during the winter months when the river is covered with ice and snow. The destruction of these organisms in the river water during the summer months is in large measure due to the growth of microscopic plants and other organisms which apparently give off dialyzable substances which are harmful to the *B. coli* and *B. typhosus*. That such substances are given off by the saprophytic bacteria was clearly shown by Frost several years ago, and my experiments confirm his by attacking the problem in a slightly different way. These effects are lost in the winter as no growth takes place at 0°C. The direct rays of the sun also are an important factor and their effects are entirely lost when the river is covered with a thick layer of ice and snow.

The practical value of this investigation is evident. It explains why some of our northern cities where sewage polluted river water is used in the water works system are more frequently troubled with outbreaks of typhoid fever during the winter months. This was illustrated at Minneapolis last winter, and I believe was true at Lawrence, Mass., before the installation of the filter. When bacteriologic analyses of sewage-polluted river water are to be made at the site of a proposed water works intake pipe, it is important that samples should be collected and analyzed both in the winter and in the summer. Analyses of samples collected during the summer do not give reliable information in regard to the

condition of that water when the river is covered with ice and snow. The analyses show that the pathogenic bacteria from the sewage travel several times as far in the water under the ice, before they are destroyed, as they will in an open river during warm weather.

DISCUSSION

DR. H. W. HILL, Minneapolis: The experiments which we undertook confirm the observations and conclusions of Dr. Ruediger regarding winter river typhoid and summer typhoid. We have found that typhoid bacilli may die out in going down the river in summer under conditions where they would exist during the winter.

DR. PETER H. BRYCE, Ottawa, Canada: I notice that the author seemingly did not take into account the question of sedimentation during the two days in the river. Pettenkofer's tests long ago at Munich showed that about 90 per cent. of all bacteria in water by dilution and by sedimentation had disappeared within a distance of 10 miles.

DR. E. C. LEVY, Richmond, Va.: At the Winnipeg meeting of this Association Dr. Freeman and I presented a joint paper on typhoid in the south, with special reference to the disease in Richmond. In that paper we brought out the point which has been explained here today, but made no attempt to explain why water-borne typhoid was especially a disease of winter months, though we proved to our satisfaction that such was the case. Our opinion was arrived at purely and simply from an epidemiologic standpoint; we had no laboratory facts to corroborate it. During the years since that time our views have been confirmed in every way to such an extent that in Richmond, after we have passed the winter months, we do not worry about water typhoid.

DR. G. F. RUEDIGER, Grand Forks, N. D.: I do not think that the factor of sedimentation would alter the experiments in any way; so far as I can see, there would be as much sedimentation in winter as in summer. This factor need not be considered in this particular study. Another study might be made based on the factor of sedimentation.

The Sanitary Registration of Houses in Mexico

DR. J. E. MONJAS, Mexico City: The board of health in Mexico has made great progress in the sanitary records of houses in that city. The plan of the city shows the houses in which persons have died of tuberculosis. Each house is shown on the plan by a number which corresponds to the number of cases observed in that house, and each one has its separate file containing all the details of cases as well as the work which has been ordered to improve the sanitary conditions of the houses. With this plan it is possible to show the number of deaths caused by tuberculosis or any of its allied affections from the year 1891, with the ages and sex of those who died, and the wards in the City of Mexico in which those deaths were recorded. The sanitary registry of the houses, therefore, constitute a necessary institution in all cities by the aid of which the sanitary and municipal authorities, as well as the general public, can obtain easy and certain knowledge of the houses which constitute foci of infection.

DISCUSSION

DR. FREDERICK TORRALBAS, Havana, Cuba: The work Dr. Monjas has described has been carried on in Havana for some years. It is the duty of the sanitary inspector to obtain the complete history of houses. An inspection is made of from 1,800 to 2,000 houses a day, so that cases of tuberculosis are easily traced.

Sanitation of Bakeries and Restaurant Kitchens in Chicago

MR. CHARLES B. BALL, Chicago: In the Chicago Department of Health's experience with bakeries and restaurant kitchens we are led to the conclusion that new installations of restaurant kitchen are required. Ample space must be provided in which the employees may perform the various operations. The contingency of expansion at a future date should be considered, as the tendency to enlarge the dining room, without providing additional kitchen facilities, is found in a great many cases. The arrangement of the various appliances in their relation to each other should insure the isolation

tion of dishwashing and garbage storage from the handling of food. Adequate provision must be made for the removal of cooking odors, not alone from the ranges, but also from vegetable boilers, so as to avoid nuisance in other parts of the building and in the neighborhood. The Underwriters' Association now requires that ventilation ducts from large ranges be built of heavy iron plate and carried through the top of the building without any other connections, so that the grease and soot may be burned out of them as from a chimney flue, without incurring fire danger to other rooms. Ample toilet facilities and wash-rooms, separate for each sex and apart from those provided for the public, must be furnished. The wash-basins should be located outside of the toilet rooms in order that it may be apparent to those in charge that the hands are cleansed after leaving the toilets. Proper locker rooms, with exceptional means of ventilation, must be provided in order to avoid the nuisance of the storage of either street or working clothes in tightly closed cupboards. Well-ventilated refrigerators are required in numbers sufficient to afford separation for the different classes of food and especially for milk and butter. The best examples of the application of these rules of design to new bakeshops and kitchens are to be found in upper stories, preferably the top story, of certain high buildings. Such installations of superior type are at present by no means rare.

Practical Methods of Supervising the Milk Supply of Cities

MR. J. BOSLEY THOMAS, Baltimore, discussed permits for the sale of milk and cream; methods of keeping records; collecting samples and recording results; methods of transporting and delivering milk; communicable diseases; diseases in houses where milk is delivered in bottles; bovine tuberculosis; supervision of dairy farms; butter-fats standards, and said that while there are many admirable methods used by various authorities in the administrative control of the milk supply, there is little or no standardization of these methods. It therefore seems advisable, he said, that some representative society or body should appoint a committee to establish or recommend standard practical methods that would be capable of universal use.

Saving Children From Milk-Borne Diseases

MR. NATHAN STRAUS, New York: The old city of New York, now the Borough of Manhattan, has established a new record in the saving of the lives of babies. Notwithstanding unusually severe periods of intensely hot weather the past summer, there have been fewer deaths of children under five years than in any preceding summer, and for the first time in the history of the city the summer mortality has fallen to a rate less than 50 per thousand per annum. When I first undertook to protect the babies of New York from milk-borne diseases by supplying pasteurized modified milk in 1892, the summer saw the dying of 6,612 children under 5 years, making the rate per thousand per annum 136.1. With the steadily increasing use of pasteurized milk there has been a steady decline in infant mortality, until the summer just ended showed only 3,900 deaths in a population of children larger by 125,000 than that of 1892. In other words, in 1892, 961 children out of every 1,000 survived the summer, while in 1910 there were 988 who escaped death out of each thousand. In my experience the saving of children from milk-borne diseases warrants the assertion that the pasteurization of milk supplies of our cities, under careful health department supervision, would infallibly reduce the death rate.

President's Address: A Renaissance in Health

DR. CHARLES O. PROBST, Columbus, Ohio: A renaissance in health is at hand. Never before has the public shown such interest and enthusiasm in health measures. Never has it so nearly reached a realization of the immense possibilities in preventing sickness and prolonging life. The time is ripe for cooperation of the widest sort. Without attempting even to outline a plan for cooperation, I would recommend that by committee or otherwise the question be investigated of the possibility of uniting or concentrating the efforts of the different national organizations in the four countries represented

whose work concerns in any large measure the promotion of the public health. If moral prophylaxis comes within the scope of social hygiene, the question of providing suitable amusement for the working people becomes of greatly increased importance. Especially is this true for working girls. The lack of such places in large cities is among the chief causes of the social diseases. The department of child hygiene of the Russell Sage Foundation, established in 1908, occupies a part of this field. Its purpose in part is to conduct researches and promote activities favorable to the physical, moral, and intellectual welfare of children, especially public recreation, and the health and progress of school children. This association stands for the highest possible standards in public health. In various ways it has given weighty support to many health movements for improving general health conditions, and notably in the interest of pure food and the establishment of a national health department. The family physician must long remain the chief instructor and most potent factor in preventing the spread of dangerous infectious diseases. The strongest nation, the one of greatest achievements, will in the end be the one that gives the greatest amount of intelligent care to the health of its subjects. Eventually all health interests should be administered by the government. If the first step towards the centralization, or at least the cooperation, of the many associations devoted to health problems can be taken at this meeting, it may be the means of hastening the day when every individual will be given time and opportunity for the pursuit of health and happiness, and the certain knowledge of how and where to find them.

Organization of the Pennsylvania State Department of Health

DR. SAMUEL G. DIXON, Harrisburg, Pa.: From July 22, 1907, to June 30, 1910, 32,247 poor tuberculous sufferers had received the skilled medical aid and the attention of trained nurses which the department's 115 dispensaries provide. The death-rate from tuberculosis in Pennsylvania has fallen from 134 to 120 per 100,000 of population in 4 years. This means a saving of 1,000 lives annually. From October, 1905, when the state began its free distribution of diphtheria antitoxin among the poor, down to Dec. 31, 1909, 20,794 patients with this dread disease, mostly little children were treated with the life-saving serum. We know by statistics that without antitoxin 42 out of every 100 of these children would probably have died, but with the aid of the state's antitoxin the death-rate among these poor little sufferers was reduced to 8.48. Free antitoxin was also given to 15,125 patients, mostly children, who had been in contact with the disease. All but a very few of these were absolutely protected against diphtheria. A very low estimate of the saving of child life resulting from the state's free distribution of diphtheria antitoxin since 1905 is about 8,000 lives, a pretty good investment of the tax payer's money. And what of typhoid fever in view of all this work for pure water? In 1906, 56.5 out of every 100,000 people died from this disease; in 1907, 50.3; in 1908, 34.4; and in 1909, 23.9. That is, there are now living 2,363 people who, had the death rate of 1906 prevailed in 1909, would have died from typhoid. In 1906 and 1907, the death rate in Pennsylvania per 1,000 of population was 16.5; in 1908, it had dropped to 15.7 and in 1909 to 15.3.

Executive Methods in Preventive Medicine

DR. HENRY B. HEMENWAY, Evanston, Ill.: Health administration was formerly local in nature. The science of public health has now advanced far beyond administration, especially in this country. The American law requires a separation of the three branches of government. Health administrators, being of the executive branch, have no legislative power. They may not, therefore, issue any orders, or regulations except as distinctly provided in the laws under which they are acting. All health authority is derived from the police power of the state. Police power is a system of precaution for the prevention of crimes and calamities. It is a necessary but also a dangerous power; and because of the danger to individual liberty, the courts are inclined to scrutinize its operations closely to prevent abuse. The police power of public health starts from the idea of nuisance, and presupposes legislative deter-

mination in great detail. Even though administered by municipal officers, public health work is essentially state in nature; and in the absence of special constitutional provisions to the contrary, the state has the right to appoint and regulate the acts of municipal health officers. The protection of the state against damage suits is extended to all health officials, so long as they act within the law, even though error has been committed, and damage results to individuals. As compared with other countries, American state executives are ill-organized and weak, and one of the weaknesses is shown in the tendency to the appointment of boards, often serving without pay. Since executives have no legislative power, an executive board loses in responsibility, decision, activity and dispatch, without compensatory advantage. There is no more reason why a physician should donate his public health service than that a lawyer should serve without pay as a judge, or a banker should give the use of the money needed for public improvements. Health laws should be enacted by the state legislature. The entire health administration of a state should be recognized as one body, having a single head to whom all local and district officials are responsible. Every man should be held responsible for a definite portion of the work.

Executive duties are either ministerial or discretionary. If ministerial, the officer may only do that which is required. If discretionary, he may do anything within that discretion; but neither his acts nor legislation for his guidance, may be arbitrary or unreasonable. If the officer acts beyond the provision of the law, he may be sued as a private wrong doer. Health legislation should be definite, not in general terms, best to safeguard individual liberty.

Matters of technical detail in the work of the office may be largely left to subordinate; but the executive must personally and frequently decide on questions of administration. In other words, the head of the department should be a professional administrator with a broad knowledge of sanitary science, not merely a sanitarian or a party politician. At least once a year there should be a conference of state and district officers, at which proposed legislation may be discussed and prepared for presentation to the legislature for enactment.

General Discussion on Public Health Matters

DR. C. A. HARPER, Madison Wis., discussed the relation between state and municipal boards of health, saying that the interchange of ideas, and the knowledge required by each health officer in knowing how other health officers do their work and meet certain emergencies, fully justifies the labor and expense incident to holding state or district conferences. If the health officer expects to impart knowledge to others, he must know his subject thoroughly and realize the important rôle which sanitation and public hygiene play in the prevention of diseases.

PROF. E. H. S. BAILY, North Dakota, spoke of the advantages of cooperation between the state board of health and state universities.

DR. GUSTAV F. RUEDIGER, Grand Forks, N. D., spoke of the relation of the state university of North Dakota to the State Board of Health, and favored placing the state board of health laboratory under the control and regulation of the state university, under the direction of the professor of bacteriology and pathology.

DR. CHARLES A. HODGETTS, Ottawa, Canada, pointed out the functions of the Canadian Commission of Conservation and Public Health.

DR. H. W. HILL, Minneapolis, spoke of the relations of universities to public health work.

MAYOR SEIBEL, Milwaukee, Wis., discussed social economics and public health, and said:

and mineral deposits. These, with machinery, are important factors in wealth production; but the most important factor of all in wealth production is human labor. Without labor of hand and labor of brain applied to raw material, there is no civilization thinkable. The greatest of all natural resources is human life with its accompaniment of labor. It is good and excellent work to conserve land and timber and water. Land has a value. Timber has a value, and so have water

Idaho April Report

Dr. O. J. Allen, secretary of the Idaho State Board of Medical Examiners, reports the written examination held at Boise, April 5-6, 1910. The number of subjects examined in was 11; total number of questions asked, 120; percentage required to pass, 75. The total number of candidates examined was 38 of whom 24 passed and 14 failed. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
Denver and Gross Coll. of Med.....	(1908) 76; (1909)		80
George Washington University.....	(1907)		77

The following questions were asked:

HISTOLOGY

1. Define and locate neuroglia, areolar, hyaline, epithelium, adipose. 2. Describe adenoid tissue. 3. Give the histology of voluntary muscle. 4. Describe the structure of the spleen. 5. Describe a cross-section of the spinal cord.

ANATOMY

1. Describe briefly the lymphatic system, giving terminations. 2. Describe the sympathetic nervous system. 3. Name the arteries given off by the abdominal artery. 4. Describe the portal circulation in detail. 5. What is Scarpa's triangle, circle of Willis, Gimbarnat's ligament, foramen of Winslow, pineal gland, thymus gland, mediastinum, oesophagus, parathyroid, antrum of Highmore?

GYNECOLOGY

1. What important blood-vessels are in close relation to the female ureters, between the bifurcation of the common iliacs and the point where they enter the bladder, and what is their distance from the uterus from each other at that point? 2. Name the most frequent causes of pelvic inflammations, avenues of infection and tissues most likely to be invaded. 3. Give causes, symptoms of and treatment for contraction of the bladder in the female. 4. Describe the operation for eradication of cancer of the mammary gland. 5. Define colpitis, colptosis, atresia, kraurosis, amenorrhea, menorrhagia, metrorrhagia, dysmenorrhea, salpingitis, proliferating. 6. Name the different varieties of dysmenorrhea mentioned in the textbooks and differentiate between the membranous form and an early abortion. 7. Describe in detail the examination of a case of suspected pelvic disease. 8. Give etiology, pathology and treatment of acute cystitis. 9. Give treatment for simple catarrhal vaginitis. 10. Differentiate between carcinoma of the cervix uteri and granular inflammation, myoma, polyp and condyloma.

PATHOLOGY

1. State the principal pathologic lesions of senility. 2. Uncinariasis, give etiology and pathology. 3. Give pathology of septicemia and of pyemia. 4. Acute anterior poliomyelitis; give pathology. 5. Describe the pathologic lesions of syphilis. 6. Arteriosclerosis; give etiology and pathology. 7. Describe the process of atrophy and of hypertrophy. Name types of each. 8. Describe the *Staphylococcus pyogenes aureus*. The *Streptococcus lanceolatus*. 9. What are infectious granulomata? Name and describe types. 10. State the pathology of Basedow's disease; of Addison's disease.

PRACTICE OF MEDICINE

1. Differentiate empyema from pulmonary abscess. 2. Differentiate aortic regurgitation from mitral regurgitation. 3. Make a diagnosis of aorta. 4. Describe the symptoms of 5. Give the symptoms and treatment of gastric ulcer. 6. Icterus hydropnephrosis. State its causes and describe its treatment. 7. Give the symptoms of (a) acute lead poisoning; (b) chronic lead poisoning. 8. Define myxo-

dema and give its treatment. 9. Describe the symptoms of a case of apoplexy due to cerebral hemorrhage. 10. Give the symptoms and treatment of locomotor ataxia.

PHYSIOLOGY

1. What is the chemical reaction of (a) blood, (b) urine, (c) sweat, (d) uterine secretion and (e) vaginal secretion? 2. Describe a complete physiologic revolution of the heart. What is the office of the columnae carneae? 3. How is asphyxia produced? What are the causes of death from asphyxia? Locate the respiratory center. 4. Name the secretions of the alimentary canal, their reactions, active principles and functions. 5. Describe by drawing or otherwise the different glands of the stomach. 6. What are the functions of the pancreas? What effect would extirpation of the pancreas have on digestion? 7. Describe the portal circulation. 8. What are the physiologic functions of the liver? 9. Describe the renal circulation. State the function of the (a) vas deferens, (b) the vesiculae seminales and (c) the prostate gland. 10. Define (a) afferent, (b) efferent, (c) trophic, (d) inhibitory, (e) motor and (f) vasomotor nerve fibers.

OBSTETRICS

1. What is the character of the liquor amnii and what are its sources and uses? 2. Name the fetal envelopes from without inward. 3. Describe the fetal heart-sounds, give their rate, and state when and where they are best heard. 4. Give the etiology, symptoms and management of albuminuria of pregnancy without structural kidney lesions. 5. Describe and give the functions of the perineal body. 6. Describe the mechanism of labor in the R. O. P. presentation. 7. What is inversion of the uterus, what are its causes and symptoms, and how should it be treated? 8. Give the causes, symptoms and prognosis of rupture of the uterus during labor, and state how such an accident should be managed. 9. What are the symptoms and physical signs of ectopic gestation? From what must it be differentiated? What is the etiology? 10. State the causes, symptoms, pathology, treatment and sequelae of puerperal phlebitis.

DIAGNOSIS

1. What is the practical import of hematuria and how can its source be diagnosed? 2. What conditions might cause alvine discharges containing fat? 3. What is the diagnostic significance of dropsy? 4. Describe the natural heart sounds. 5. Differentiate empyema from pulmonary abscess. 6. Give the causes of vertigo. 7. Give the area of normal heart dullness. What conditions increase the area of heart dullness? 8. In what diseases can we employ the microscope to advantage as an aid in diagnosis? 9. Give the differentiating points between rubeola and röteln. 10. Give the physical findings in the different stages of lobar pneumonia.

MATERIA MEDICA AND THERAPEUTICS

1. Define and describe alkaloids. 2. Name five changes of the official Latin titles in the eighth revision of the U. S. P. 3. Give the official names of wahoo, pennyroyal, corn silk, oxgall, nutmeg, chamomile, hemlock, yellow jasmine and Rochelle salts. 4. Name the official preparations and doses of digitalis, cascara sagrada, ipecacuanha and strophanthus. 5. Give the official name, the ingredients in and dose of Tully's powder. 6. State the composition and method of preparing liquor potassii citratis. Should it be freshly prepared? Has the strength of liquor ferri et ammonii acetatis been increased or decreased in the eighth revision of the U. S. P. and to what extent? 7. What is incompatibility in medicine, and what are the different kinds of incompatibles? Give an example of each. 8. Give the physiologic action and therapy of saline purgatives. 9. What therapeutic uses has chloroform other than as an anesthetic? 10. Explain the distinction between physiologic action and the therapeutic use of medicinal agents.

CHEMISTRY AND TOXICOLOGY

1. Give symbol, atomic weight and source of bismuth. (b) Name official preparations. (c) State how citrate of bismuth is prepared without giving proportions. 2. Give chemical formula, correct name and source of black oxide of manganese. 3. Give formula for chromic acid. (b) What is its appearance and solubility? (c) How used medicinally? (d) How is it affected by alcohol, ether, glycerin and other organic solvents? 4. Explain the chemical reaction that takes place in the preparation of spts. mindereri. (b) Also in the preparation of liquor potassii citratis. 5. Give common name for $ZnSO_4$, KNO_3 , KBr , $KClO_3$, $Zn(OH)_2$, $Zn(C_2H_3O_2)_2$. 6. What would you do if you were called to a case of poisoning supposed to be caused by arsenic? (b) Strychnin? (c) By formaldehyd? 7. How is chloral made? (b) What is the best treatment of poisoning by it? 8. Give the antidote for poisoning by iodine, aqua ammoniac. 9. What is the source of creosote, its dose, purpose used and antidote? 10. Should or should not oil be used in phosphorus poisoning? Give reason for your answer.

HYGIENE

1. What relation do ground air and ground water bear to each other and to disease? 2. Name four diseases reduced to their minimum of frequency by the lowering of the ground water and purification of the soil? 3. What property do those pathogenic germs possess, which retain their existence for long periods, outside a natural medium of growth? 4. What are the purposes fulfilled by food, and under what heads are the proximate constituents of food and the various food substances classified? 5. How many ounces of water free food are required for daily subsistence, (2) for ordinary work, (3) for laborious work? 6. What are the most favorable conditions for the care and preservation of milk? 7. Explain the germ theory of the contagia and how immunity is produced by the disease itself. 8. What are the objections to tent life for consumptive patients during the summer, and how can they be met by tent construction? 9. What beneficial effect has domestic cooking on tuberculous meat and milk? 10. Define zymotic, contagion, intoxication, specific, communicable, caloric, hygienic, sanitary.

Book Notices

STUDIES IN RELATION TO MALARIA. By Samuel T. Darling, M.D., Chief of Laboratory of the Board of Health, Department of Sanitation, Isthmian Canal Commission. Paper. Pp. 28. Washington: (Superintendent of Documents) Government Printing Office, 1910.

In many malarial regions it is important that the varieties of mosquitoes common to such regions should be recognized, their breeding-habits studied and a determination made of the species of anophelines capable of transmitting the disease. This is explained by Samuel T. Darling, chief of the laboratory of the board of health of the Canal Zone, in a pamphlet issued by the Isthmian Canal Commission. The anophelines insusceptible to malaria may be more limited in their choice of breeding-places than the other varieties, so that in the work of malarial mosquito destruction the latter may be disregarded, and attention given wholly to the breeding places of those varieties responsible for the transmission of malarial fever. With regard to man as a host it is necessary to have some knowledge of the limits of his infection-ness, i. e., the number of the sexual forms of the parasite in the blood necessary to infect susceptible mosquitoes. Other matters of importance are latent malaria, the effect of quinin on the parasites in man, the value of larvicide, algacides, agents destructive of ditch-grass, the size of screen mesh necessary to keep out mosquitoes, etc. After giving a minute description of the different species of anophelines and naming those susceptible to infection with the malarial parasites as shown by his experiments, together with the methods of conducting the experiments, collecting the larvæ, breeding, biting and infection experiments, estimation of gametes, care of the mosquitoes after biting, examining for zygotes, description of the malarial parasites in the mosquitoes, blood examinations, etc., Darling states that it was noticed that patients were discharged from the hospital after the temperature was normal but while the peripheral blood still contained more than a sufficient number of gametes to infect susceptible mosquitoes. Experiments were therefore carried out to determine the limit of infectiousness of such individuals, and it was found that persons with more than 2 gametes per centimeter must be regarded as gamete-carriers, and should not be discharged or treatment discontinued until the gametes were reduced well below the limit of infectiousness, which was determined to be 1 gamete for every 500 leukocytes. This question of the complete destruction of the sexual forms in man is generally overlooked, but is important in delimiting malaria, and may be accomplished by appropriate quinin treatment of all gamete carriers. Thirty grains of quinin sulphate daily is an efficient dosage for the purpose, although this quantity had no effect on the development of the parasites in infected mosquitoes fed on the blood of individuals taking this amount of quinin. The effect of quinin administration is to make the gametes in the tertian form, at least, gradually disappear from the peripheral blood of the patient by the destruction of the young forms, the gametes being phagocyted by splenic and hepatic endothelium; this will occur in from a few days to a few weeks, depending on the severity of the infection. There are never as many gametes in the peripheral blood in the tertian form as in the estivo-autumnal form. In the investigations to determine latent malaria among laborers at work it was found that from 8 to 13 per cent. were carriers of the parasites, chiefly of the tertian variety, or in the proportion of four to one of the estivo-autumnal. It is this latent, untreated malaria in every tropical community which contributes largely to the infection of anophelines when, after the onset of the rainy season, mosquitoes have begun to breed in numbers. Many other points concerning the disease, the parasite and the mosquito, are taken up, the whole making an interesting and valuable contribution to the subject.

MANUAL OF TROPICAL MEDICINE. By Aldo Castellani, M.D., Director of the Clinique for Tropical Diseases, and Albert J. Chalmers, M.D., Registrar and Parasitologist, Corson Medical College, Philadelphia. Price, \$6 net, Pp. 1242, with 372 illustrations. New York: Williams Wood & Co., 1910.

This book represents, according to the authors, the knowledge found actually necessary to acquire and use in their work in tropical medicine. A mere glance at the volume of 1,200 pages shows the wide scope taken by tropical medicine

at the present day. This department of medical science may be said to be based on the agency of animals in the conveyance of disease, and consequently a very large section of the work, covering nearly 400 pages, is devoted to a description of the biologic causes of disease, including animal parasites and disease-carriers and a short chapter on the vegetable parasites, omitting bacteria, which are sufficiently described in other text-books. The animal parasites and carriers are arranged according to their zoologic order, and a very complete description is given. The following section of about 600 pages treats of the diseases of the tropics, including those which are in any way characteristic, chiefly the infections. The authors have, however, not neglected other affections which present any unusual features in tropical countries. Thus we find certain monsters described because these births occur in tropical countries more frequently, according to the authors' experience, than in cooler climates.

Treatment has been described in detail, which adds value to the book, as it may be the only authority which the worker in a tropical climate has at hand. Specific directions for the administration of medicines are given in such diseases as dysentery, ankylostomiasis, malaria, etc.

The work shows great research and presents a mine of valuable information. Its value is much enhanced by the abundant illustrations, numbering 373, besides 14 colored plates. The usefulness of such a work is by no means limited to those practicing in tropical countries, for a large proportion of the subjects treated find examples in temperate climates, as for instance, malaria, plague, amebic dysentery, pellagra, etc., while those more closely confined to tropical regions may be brought unexpectedly to the notice of the American or European physician by returned travelers or soldiers. To the physician who recognizes the need of acquainting himself with tropical diseases this work will present a welcome aid.

DIE ORTHOPÄDIE DES PRAKTISCHEN ARZTES. Von San.-Rat Dr. Georg Möller, Berlin. Paper. Price, 8 marks. Pp. 258, with 151 illustrations. Vienna: Urban & Schwarzenberg, 1910.

This practical little volume of 258 pages is written, as its title indicates, for the express purpose of diffusing among general practitioners knowledge of such later developments and methods in the realm of special practice as they are not only quite competent to understand, but are well able to follow out in practice, once it is brought to their notice in a plain and logical manner. The author covers a rather complete range of orthopedic treatment with necessarily short discussions of etiology. The directions are practical and clear and their execution may be within the range of the general practitioner if he is fairly ingenious. It is interesting to note, however, a conspicuous absence of our practically indispensable Bradford frame in the treatment of Pott's disease, and complete obliviousness of the name of Grattan when mentioning instruments for osteoclasis; nor is it any less surprising to know that the author removes all dressings ten days after a myotomy for correction of torticollis, depending on massage, gymnastics, and similar therapeutic measures to maintain the correction. In the etiology of spondylitis deformans, while mentioning gonorrhea, rheumatism and uric acid, he omits the pyogenic factor so familiar to us in our later experiences. Possibly we are expecting too much in a book of such limited scope; but there is so much in it that is direct and practical that it should be gratefully welcomed by those whom it is specially designed to serve. The mechanical features of the book are good and the illustrations well chosen and instructive.

NURSING IN DISEASES OF THE EYE, EAR, NOSE AND THROAT. By the Committee on Nurses of the Manhattan Eye, Ear and Throat Hospital, New York. Cloth. Price, \$1.50 net. Pp. 281, with 81 illustrations. Philadelphia: W. B. Saunders Co., 1910.

In this book the opening chapters on the germ theory of disease, antiseptics and disinfection of rooms and clothing, sterilization, preparation of operating-room, duties of the nurse at operations, duties in emergencies, feeding and care of infants, etc., do not differ materially from other works on nursing not intended especially for nurses in eye, nose, throat, and ear cases. The anatomic descriptions of the organs and structures included in the scope of the book are sufficiently full and clear for the purposes of the work;

and they are well illustrated; but in the descriptions of diseases and operations or procedures, their application or pertinence to the work of the nurse is not always set out or clearly manifest, although the authors assert that it has been their purpose to keep that relation in mind, as, for instance, in the descriptions of the tuning fork and other diagnostic methods of determining the condition of the hearing apparatus. For the most part, however, such things are avoided, and only such information presented as to give the nurse an intelligent understanding of the duties required of her. It may be questioned by many, however, whether works on nursing giving the general principles would not answer the purpose without requiring a special work for these branches.

SERUMS, VACCINES AND TOXINS IN TREATMENT AND DIAGNOSIS. By W. Cecil Rosanquet, M.D., Assistant Physician to the Charing Cross Hospital and to the Hospital for Consumption and Diseases of the Chest, Brompton, and John W. H. Eyre, M.D., Bacteriologist to Guy's Hospital and in Charge of the Vaccine Department. Second Edition. Cloth. Price, \$2 net. Pp. 362, with illustrations. New York: Funk and Wagnalls Co., 1910.

This is a pocket manual of 360 thin-paper pages. The authors devote 60 pages to a consideration of the general principles of immunity and susceptibility and the relation of specific bodies thereto. They then take up about a score of diseases or syndromes for which serums, vaccines and antitoxins have been advocated. With some of these substances the authors have had experience and have written from that point of view. In connection with most of them, however, they review the literature and give more space to American literature than is usual in English or European books. The book would be more valuable if the authors spoke with more of personal conviction on many points.

The subjects discussed are too new for anyone to write a really satisfying book on them. Certainly views have not crystallized enough for the purposes of a manual of a certain type. There is a field for a book that gathers together references for those who want to know of the subjects treated in this volume and have not the time or the training to go deeply into them. Such a manual as this should be revised at short intervals.

HYGIENE AND PUBLIC HEALTH. By B. Arthur Whitelegge, M.D., late County Medical Officer of Health for the West Riding of Yorkshire, and George Newman, M.D., Lecturer on Public Health at St. Bartholomew's Hospital (University of London). Cloth. Price, \$1.75 net. Pp. 650, with illustrations. New York: Funk and Wagnalls Co., 1910.

The book covers a wider range of subjects than is customary in American books. The terms used occasionally differ from those in use in this country. A good deal of space is occupied by laws and rules, many of which are not adaptable to this country. Nevertheless, in the absence of standards in America, these rules constitute a most valuable part of the book. This is one of the best manuals in any language.

Medicolegal

Validity and Construction of Contract for Medical Treatment for Life; Payment to Be Out of Estate—Licensed Physician of One State Treating Patient Temporarily in Another State

The Supreme Court of Illinois had in *Zeigler vs. Illinois Trust and Savings Bank* (91 N. E. R. 1041) a case wherein it was sought to enforce a contract providing for payment for medical services for life by a patient's estate. The contract stated that the patient had entered into an agreement for professional services to be rendered by the claimant, a physician, at any time or place, during any spell of indisposition to which the patient might be subjected during the remainder of her natural lifetime; that in the event of sickness such methods were to be employed or adopted as seemed best and most expedient; that all medicine or other paraphernalia necessary to the discharge of duties in cases of indisposition were to be provided by the physician; that when the critical moment came, when it was thought that the patient might pass away, the physician might call another physician or physicians as judgment might dictate; and that it was voluntarily contracted to pay for the services thus rendered \$100,000, payable immediately or as soon as possible by the

patient's estate. The contract was made in Chicago, in December, 1899, and re-executed or confirmed in July, 1901, the patient being at the former date about 78 or 79 years of age, and living until August 25, 1904, when she died, in California. Her estate was valued at \$270,000.

The Appellate Court, First District of Illinois, held that the contract was void, as being against sound public policy. But the Supreme Court of the State reversed its judgment and holds otherwise. That this contract did not in any of its expressed provisions violate the constitution or any statute of the state, the Supreme Court says, did not admit of argument. The making of such a contract is not prohibited either by the express terms or any fair implication of the constitution or of any statute of the state. Neither does the court deem it to be contrary to the judicial decisions of the state. The laws and the public policy of the state permit and require that utmost freedom of contracting between competent parties, and it is only when a contract expressly contravenes the law or the known public policy of the state that courts will hold it void.

It was urged that this contract was void chiefly for the reason that it furnished an incentive to the physician to shorten the life of the patient by neglect or improper treatment or by the commission of the crime of murder. Each argument made in support of that contention involved a breach of the contract, and was not founded on the performance of it. It could not be seriously contended but that, in order to comply with the terms of this contract and be entitled to receive the benefits of it, the physician was bound to give the patient the best treatment within his power and skill and to prolong her life as long as possible. Should he fail to do this, either through neglect, by willfully treating her in an improper manner or by directly causing her death, he would be unable to recover on the contract.

There can be no doubt that a contract to commit murder or any other crime, or a contract to give a reward to one for the commission of a crime, is void, as against public policy. But this contract did not contemplate the commission of a crime or the doing of anything which was unlawful or contrary to good public morals. Even if it be conceded that the contract, under its terms, offered some incentive to the physician to commit a crime, that would not necessarily render it void. There are numerous decisions involving contracts entered into whereby one party has agreed that on his death his property, or certain specific portions of it, shall go to and become the property of the other party for considerations named, being usually the caring for and maintaining of the grantor during his or her lifetime by the other party, or whereby one party conveyed his property to the other for the consideration of the care, maintenance and support of the grantor during the remainder of his or her natural life, and these contracts have universally been held to be valid and binding. In every such case, the incentive to hasten the death of the grantor was present to the same extent as in this case.

The contention that this contract was void for the reason that it was a wagering contract was also not well founded. As this court views it, it had none of the elements which would bring it within the designation of a wagering contract. There was a sufficient consideration moving between the parties to support the contract.

The interposition of the further defense that the fiduciary relation of physician and patient having existed between the parties at the time of the execution of the original and supplemental contracts they were presumptively fraudulent and prima facie void, merely made it necessary for the physician to show, by a preponderance of the evidence, that the patient entered into this contract voluntarily, deliberately and advisedly, knowing its nature and effect, and that her consent was not obtained by reason of the power and influence to which the relationship between them might be supposed to give rise.

About four months before her death, the patient, accompanied by the physician, went to California, where she died. The physician accompanied her and attended her there, under a special arrangement made with her. It was conceded that

he was not licensed to practice medicine in the state of California, and it was insisted that for that reason he was not entitled to recover anything for his services performed in the state of California, whether rendered pursuant to a contract or otherwise. But the physician, when in attendance on the patient, under the terms of his contract, while she was sojourning temporarily in the state of California, was licensed to practice medicine in the state of Illinois, and, so far as the determination of the questions involved here was concerned, it was immaterial whether he had authority to practice medicine in the state of California, or whether the medical attention he gave to this patient while in the state of California was in violation of the laws of that state. He was not engaged in the general practice of medicine in California, but was simply in attendance on his patient, who was a resident of Illinois, while she was temporarily in California.

Then, it was contended that the physician violated the terms of his contract in refusing to accompany the patient to California in 1903, and for that reason was not entitled to recover on the contract. But a fair and reasonable interpretation of the contract would not require him to accompany her to any place she might see fit to go temporarily, for the purpose of treating her professionally, but only bound him to treat her at her permanent place of abode. That the parties so understood the terms of the contract was evidenced by the fact that when he did accompany her to California, in 1904, it was under a special arrangement whereby he was to receive extra compensation for doing so.

From a consideration of the whole record the Supreme Court is of the opinion that the contract was a valid and binding one, and that the physician, having fully performed it on his part, was entitled to an affirmation of the judgment of the circuit court in his favor.

License Need Be Filed in County of Residence Only

The Supreme Court of Washington says, in *State vs. Dechmann* (107 Pac. R. 858), that, in prosecutions under the statute of that state for practicing medicine without a license, evidence that the defendant has failed to file a license with the county clerk, as required, is *prima facie* evidence that he is not a legally licensed practitioner. But, under the law, the failure to file the license in a county other than the county in which the defendant resides will not be proof of the violation of the law or the commission of the crime charged, because it is not one of the requirements of the statute that the practitioner shall file the license in counties other than the one in which he resides, even though he may be called to another county for the purpose of practicing his profession temporarily. Hence a conviction cannot be sustained by evidence showing merely that the defendant practiced medicine in a given county, and that no license had been filed in such county, without any proof that he was at the time a resident of the county.

5. Simplified Method for the Transfusion of Blood.—This method devised by Fauntleroy consists in a vein-to-vein anastomosis by means of a curved glass tube, $\frac{1}{8}$ inch inner diameter and 3 inches in a straight line from tip to tip. Each end of the tube is slightly flanged to prevent slipping out of vein after ligature is tied. The veins at the elbow are the ones selected for use in both donor and recipient and, depending on the position occupied by the individuals, a full curved or an S-shaped tube is used, the former being known as the "hand-to-shoulder" tube and the latter as the "shoulder-to-shoulder" tube. In other words, when the transfusion is done with the donor and the recipient lying in the same direction, with their shoulders touching, or nearly so, the S-shaped or "shoulder-to-shoulder" tube is used, as the direction of the venous current in this position is the same in each individual. If for any reason the reverse position is selected, such as where the head of the donor is near the lower extremity of the recipient and where the hands of each are near the other's shoulder, the U-shaped or "hand-to-shoulder" tube is used as, in order to effect an anastomosis, the venous current from the donor has to be switched around into the venous current of the recipient which is running in the opposite direction. In making this tube, which is curved to represent the arc of a circle 3 inches in diameter, one arm extends below the semi-circle $\frac{3}{4}$ inch, and it is this end of the tube which is inserted into the recipient's vein.

10. Treatment of Syphilis with Dioxydiamidoarsenobenzol. — So far, Weichselmann has treated over 600 cases of syphilis with this remedy. He says that the erosive chancres become clean after from 12 to 24 hours and heal rapidly; in pronounced sclerosis the cleaning process is of the same rapidity, but absorption takes longer. In 4 cases there appeared after the healing of the primary lesion an exanthem which healed spontaneously in 2 cases in which it appeared on the first and seventh day after the injection; the 2 other patients received a second injection. Mucous patches of the mouth heal in from 24 to 48 hours, even if the patient is an inveterate smoker. The roseola disappears in a few days, as do also the malign ulcerous syphilides, the rupia, the watery papules, the small papulous syphilides, which are otherwise so pertinacious, and the gummata. Slower is the disappearance of the large papulous syphilides, and for these a second injection becomes sometimes necessary. Favorable are the effects on syphilis of the bones; especially the night pains of the bones disappear as by magic. In view of experience with other arsenical preparations Weichselmann sees that every patient has his eyes examined by a specialist before giving the injection. In cases in which there are changes in the optic nerve—a circumstance which frequently occurs—he has not given an injection. Visceral lues also shows quick recovery, especially syphilis of the testicles and of the brain (epileptoid attacks). Icterus which has existed for a considerable time disappears in 10 days. Syphilitic growths of the larynx which had produced such severe dyspnea and stridor that the case was received as one for tracheotomy disappeared quickly and remained only as solid infiltrations, which were treated 4 weeks later with a second injection; and edema of the larynx, of which he was very much afraid at first, did not occur. Two patients with tumors from cerebral lues stood the injections well, although the symptoms were very severe. The same was the case with 2 patients

who had only lately suffered a luetic apoplexy, and a patient with a luetic apoplexy a few weeks old; these 3 patients plainly showed improvement. As to the parasyphilitic diseases, Wechselsmann has not observed clear results in cases of progressive paralysis, although he is of the opinion of Alt, that a trial should be made in early cases. At all events, a favorable influence will be produced on the symptoms of lassitude, depression, and abnormal irritability, which occur early and quite threateningly. In tabes also a quick improvement has been plainly noticeable. Altogether, the tabetics are very well satisfied. Some symptoms seem to improve in some cases: for example, the girdle sensation; the dull headache which had existed for years; very severe intercostal neuralgias: in one case weakness of the muscles of deglutition, which had existed for a number of years and which produced difficulty in swallowing dry nourishment. Diminished potentia cœundi was in one case so improved that daily intercourse was accomplished. A debility of the sphincter vesicæ which had existed for 8 years, and on account of which diurnal incontinence occurred, while on a sudden impulse immediate evacuation of the bladder took place, disappeared a few days after the injection. In 2 cases an improvement of the rigor pupillæ was shown, also an improvement of the disturbances of sensibility. Furthermore, some patients state that the gait is improved. In advanced cases, Wechselsmann says that one cannot hope for success, but we must not forget that there exist in paralysis and especially in tabes, besides the process which cannot be repaired, such as scleroses of certain systems, syphilitic lesions, especially of single vessels, gummata, meningitic growths, particularly in the atypical forms of tabes, pseudotabes, in which an improvement is possible. It is evident that such an improvement is of the greatest import for the patient even if the improvement occurs in small, circumscribed locations in an organ, as, for example, the spinal column, where so many important nerve courses are crowded together in the smallest space. Several observers, such as Truffi, Pazini, and especially Wechselsmann's assistant, Dr. Siesskind, have proved that the spirochetes disappear from papules and primary lesions, in some cases after 24 hours, while in other cases they still exist after days, even if they are swollen and very little movable. Iversen has lately made similar observations in preparations of glands.

The Wassermann reaction usually disappears, as has been stated by Alt, and Lange has found that a time from 8 to 40 days is necessary to produce this effect, according to the primary severity of the reaction.

Wechselsmann has not observed bad after effects of importance, but it has been found that otherwise light infections, such as those with coryza or angina, even if they appear on the ninth day, are accompanied with very high fever, with a temperature from 104 to 105.8 F. A patient with a weak heart should therefore be carefully guarded; besides, in such cases the injection seems not to be without danger. Otherwise, the influence of the remedy appears generally to be of an exciting and invigorating nature. It can therefore be given with benefit to very miserable patients, as, for example, to the tuberculous, in contradistinction to mercury. Nor has he observed widespread and severe recurrences, such as occur after mercurial treatment. Isolated cases have remained refractory and made a second injection necessary, which was then successful as in cases of recurrence. Although, naturally, it cannot be positively stated whether it will be possible to cure syphilis permanently, Wechselsmann hopes that we shall be able to do this in certain cases.

- 23 Necessity of the General Practice of Medicine as a Preliminary Training for Those Engaged in Special Work. C. M. Cobb, Boston.

20. Results Following Operation for Hernia.—Scudder reports 244 operations done by him for hernia of all kinds. There have been no deaths following operation in uncomplicated cases.

The only deaths were in the strangulated group. There were 25 patients with strangulated hernia; 10 of these died; 3 hernias were inguinal, 1 hernia was ventral, 1 was femoral, and 5 of the 10 fatal cases were umbilical. These 10 deaths make a mortality of 40 per cent in the strangulated group.

Scudder succeeded in obtaining the present condition of 158 of these cases. Of the 158 operations, 143 wounds are solid and without recurrence. That is, 90.6 per cent. of the patients operated on in whom the returns were known were cured. There were 165 patients with inguinal hernia; 53 did not report; in 3 strangulated cases the patients died; 10 of the 109 in whom the end-result is known recurred. That is, 90.9 per cent. of the patients in the inguinal group were known to be cured.

There were 27 cases of ventral hernia; 11 patients did not report; in 1 the hernia recurred; 1 died of strangulation; 14 of the patients in whom the end-result was known were all right. That is, in 93.33 per cent. of the cases reported the patients were cured.

There were 13 umbilical cases. There was no report from 3 cases. Of the remainder, 5 patients died of strangulation; 5 had no recurrence.

There were 5 epigastric hernias. All of these patients reported, and each is well.

There were 2 congenital cases, in each of which the patient died.

It will thus be seen after a careful analysis of the returns from these cases of hernia that there are comparatively few recurrences following the procedures employed. This investigation into the condition of these hernia cases was undertaken primarily to determine whether any material change might be necessary in the technic of the operation to secure better results. In analyzing the 10 cases in which recurrence is known to have occurred in the inguinal hernia group, conditions were present which precluded, perhaps, the possibility of cure. In certain (2) of these cases a chronic cough which had persisted for years contributed to the recurrence. One case was a strangulated case, and it is very likely that the operation was done with such haste on account of the condition of the patient that the technic was not so satisfactory as it might have been. In the other 7 cases there is no explanation apparent for the recurrence. Scudder thinks it fair to say that the Bassini operation for inguinal hernia is most satisfactory and that if carefully performed gives at least a cure in 90 per cent. of the cases and possibly in 95 per cent. (Coley). There was no mortality attending these operations for hernia. In certain of the strangulated cases the patients recovered; in 10 strangulated cases the patients died.

29. **Therapeutic Action of Digitalis.**—Henderson is convinced that Fraenkel's method of intravenous administration of strophanthin puts into the hands of the physician a valuable means of overcoming cardiac weakness promptly. The mode of application is so certain, its effect so striking, that it might almost awaken suspicion that such drastic action might damage the heart. It might be felt that, in order to maintain the circulation when the cardiac rate is so suddenly decreased, a very great increase of work must be done by the heart. This is certainly true for each individual beat, but if one takes the total amount of work done during a unit of time, this is by no means necessarily the case. We must remember, however, that even if the heart is doing a greater amount of work in each interval of time, we have increased its ability to do work owing to the increase in the contractibility of the muscle cells, and have also decreased the danger of cardiac failure by increasing the tone of the heart muscle. We have also probably improved the nutrient conditions of the muscle, as digitalis increases the flow through the coronary vessels.

30. **Hypersecretion of Gastric Juice.**—Friedenwald's observations extend over a series of 14 cases. Of these, there are 12 males and 2 females, ages varying between 18 and 64 years. The symptoms are largely those of gastric neurasthenia, consisting of fullness, pressure, distention, eructations and pains in the region of the stomach, together with occasional attacks of nausea and vomiting, rarely of heartburn, and usually with extreme constipation. In all cases general nervous symptoms are manifested, as lassitude, headache, insomnia, irritability and depression. A marked feature of the cases is the variability of symptoms; periods of discomfort alternating with unaccountable periods of well-being, the periods of discomfort apparently often being induced by nervous influences, such as shock or anxiety. A symptom present in all instances is the emaciation; a loss of weight of from 15 to 32 pounds is observed in his cases. This is especially striking, as the appetite and amount of nourishment consumed were not abnormally diminished in any instance. Localized areas tender to pressure were observed in only 2 cases, but were inconstant. A marked succussion sound was detected in all cases long after meals, and even after small meals. Three of the cases were complicated with an enteroptosis; in none was the stomach dilated. The following examinations were made in all instances: (1) Extraction and examination of the gastric contents one hour after taking an Ewald-Boas test breakfast; (2) an examination of the gastric contents made one hour after taking a dry test breakfast; and (3) an attempt was made to extract and examine the contents from the fasting stomach. At least 3 examinations were made in all instances. In these 14 patients, 8 presented hyperacidity, 5 normal acidity ranged between 94 and 70; free hydrochloric acid between 74 and 44; in the normal cases, the total acidity varied between 64 and 42; free hydrochloric acid between 42 and 32; in the subacidity case the total acidity was 28; free hydrochloric acid. In the hyperacidity cases there was a marked interference with the amyolysis with the formation of amidulin. In the cases with a normal percentage of acid erythrodestrin was formed; while in the subacidity case, achroodestrin was obtained. With the dry test meal 2 of the patients presented hyperacidity, 4 normal acidity, and one subacidity. In the hyperacidity cases the total acidity varied between 85 and 80, the free hydrochloric acid between 68 and 72. In the normal cases the total acidity ranged between 40 and 58, the free hydrochloric acid between 34 and 46; and in the subacidity case the total acidity was 20; free hydrochloric acid, 5. In the hyperacidity cases there was a formation of amidulin; in the cases with a normal percentage of acid, erythrodestrin; in the subacidity case, achroodestrin. The extraction of contents from the fasting stomach was attempted in all instances. In not one of the cases could more than from 10 to 15 c.c. of contents be obtained. The treatment is largely the treatment of nervous dyspepsia. As most patients have lost much flesh and strength, the best results are obtained by means of the rest cure. In 5 of Friedenwald's cases in which this form of treatment was undertaken, excellent results were obtained. Ordinarily

the diet should consist of 3 meals a day, as all food ingested has a tendency to increase the gastric secretion. The nourishment should contain an excess of proteins and fats and a small proportion of carbohydrates. Of the proteins, milk, eggs and fish are to be preferred, as they do not tend to increase the gastric secretion as much as meat. Fats decrease the acid of the gastric secretion and are therefore highly recommended; they should be given as butter, cheese, cream and olive oil. The carbohydrates should only be allowed in the most digestible forms, as vegetables in puree form, dextrinized flour, and stale bread and toast. The quantity of fluids ingested need not be decreased in this affection. Large quantities of milk and alkaline waters may be taken with benefit. Such food as bouillon, meat extracts, coffee, tea and alcohol, as well as all acid and spiced foods, should be avoided. The alkalies, with or without belladonna or its preparations are often serviceable in the treatment of this disorder. Such measures as hydropathic procedures, massage, etc., which have a tendency to build up and strengthen the nervous system, are of great service in the treatment of this condition.

32. **Congenital Heart-Block.**—The hypothesis which the authors formulate to explain their cases is that they are dealing with a congenital physiologic and perhaps anatomic abnormality in the auriculoventricular bundle or its blood supply, by virtue of which conductivity is restored more slowly than normally.

33. **Duration of Pregnancy.**—The rule employed by McDonald is as follows. The duration of pregnancy in lunar months is equal to the height of the uterus in centimeters divided by 3.5. It depends on the more or less regular growth of the uterus of 3.5 cm. each month of 4 weeks, and is very exact after the sixth month. The measurement is taken with the patient lying flat, and one end of the tape is placed at the upper border of the symphysis, while the other is held by the thumb into the palm of the hand. The fingers of the upper hand are held at right angles to the fundus of the uterus, and the tape follows the contour of the uterus save at the last dip. Multiparae with lax abdominal walls and thin uteri should be supported at the side, so as to bring the occipitococcygeal axis of the pelvis into the long axis of the mother's body. McDonald says that this method gives satisfactory results and is the most exact means of estimation of the duration of pregnancy. It is strictly an estimation of the size of the fetus; for when the uterus arrives at the height

35

of 35 cm., or full term ($= 10$ lunar months), the fetus

3.5

is of a weight of 3,300 gm., or average size, as is shown by the measurement in a former paper. Thus an average-sized baby usually comes at the average period of pregnancy—hence the rule. After the sixth month this rule is extraordinarily exact, he asserts, and is most useful in determining the date of labor and the size of the fetus, when the date of the last menstruation has been forgotten. It has been in use by McDonald since 1904, and he has had good reports of it from many obstetricians. It may be said that 35 cm. is the usual height of the uterus at full term with a fetus of 3,300 gm. For every centimeter of height above this measurement approximately 200 gm. should be added to the weight of the fetus. Thus, a uterus measuring 37 cm. would contain a fetus weighing 3,700 gm. The measurements are more exact below 35 centimeters than above that height. The so-called sinking of the fetus in the last 2 weeks of pregnancy causes but little error in the measurement, as the head, when the patient is recumbent, rides upward on the pelvic bones and the sinking is not a factor. Sinking in his experience is not common in primiparae, and its supposed presence is often due to the stretching of the abdominal muscles and not to descent of the head into the pelvis. The fundus thus comes lower in the erect position, and no diminution of the fundal height is noted in the recumbent. Sinking does, however, in multiparae sometimes complicate the measurement, but not often. Hydramnios also causes but small error, as the excess of liquid does not affect the fundus, but the body of the uterus

leaving the height of the fundus to be determined by the occipitococcygeal measurement and the size of the fetus. The rule gives the most exact means at hand of prognosticating the date of labor. Thus, if the fundus measures 26 centimeters from the symphysis, the duration of pregnancy is 26 divided by 3.5, or 7 $\frac{3}{7}$ lunar months, and the patient has 2 $\frac{4}{7}$ lunar months to go to term, or 10 weeks and 2 days. This rule, combined with the estimation of pregnancy by reckoning from the last menstruation, gives a fairly exact determination of the probable date of labor.

36. Psychasthenic Attacks.—All Orbison's patients were females with an asthenic mental condition that is unquestionable. Ignoring the attacks themselves, every case would be diagnosed psychasthenia. All the patients feared epilepsy or insanity, and the assurance that these fears were groundless was a great boon. The treatment consisted in mental and physical hygiene, together with rest or exercise, as seemed to be indicated.

40. Effects of Injections of Killed Streptococci.—Weaver says that destruction of streptococci within the body is accomplished through phagocytosis, for which opsonin is essential. In estimating the ability of the individual to cope with streptococcic infections, the leukocytes as well as the serum must be taken into account. Killed streptococci when injected into an animal may raise its resistance to living, virulent streptococci. It is desirable that injections of killed streptococci as a prophylactic against scarlet fever be tried under conditions favorable for control. Heating interferes with the antigenic properties of streptococci. These properties are preserved when streptococci are killed by a strong galactose solution. Injections of galactose-killed streptococci early in the course of scarlet fever do not prevent later streptococci complications. Injections of galactose-killed streptococci in cases of acute erysipelas and in the acute stage of streptococcic complications of contagious diseases appear not to influence the course of the disease. In subacute and chronic erysipelas and in streptococcic complications of contagious diseases which have become chronic, injections of galactose-killed streptococci are sometimes followed by favorable results, and at other times no appreciable effect is seen. Great caution must be observed in ascribing improvement in these cases to the injections.

48. Mortality Decrease Following Water Purification.—The authors record in great detail the results of their observations which confirmed the findings of Mills and Reincke that the mortality from all diseases—not only typhoid—decreased appreciably as the result of water purification.

49. Anaphylactic Shock in the Dog.—These observations show that anaphylaxis in the dog is characterized subjectively by a sudden and persistent fall in blood pressure followed by objective symptoms referable to cerebral anemia.

Exsanguination and transfusion experiments demonstrate that the disturbance is due to a reaction in the fixed cells and not to changes occurring primarily or secondarily in the circulating blood. Experiments in which the peripheral and central vasomotor mechanisms have been separated by various methods (section, decapitation, destruction of the cord, and isolated circulation) show that the chief influence is exerted on the peripheral vasomotor system. Pharmacologic experiments point to an influence on the nerve endings rather than to one on the muscle of the vessels.

50. Influence of Chloral Hydrate on Serum Anaphylaxis.—In a preliminary communication Banzhaf and Famulener stated that they believed that with improved technique in the dosage of chloral hydrate it would be possible to protect 90 per cent. of all fully sensitized guinea-pigs. Now, however, they have come to the conclusion that, if the smallest dose of serum which will just kill any animal of a given series of sensitized guinea-pigs regularly, be injected into the remainder of the animals of the same series of sensitized guinea-pigs, when properly under the influence of chloral hydrate, protection will be afforded in practically all cases.

51. Studies of *Bacillus Coli*.—There has been much discussion and uncertainty as to the delicacy and relative value of dextrose broth and lactose bile in testing water of fairly good quality. The present investigation was undertaken by Hale and Melia with a view to throwing light on this subject. They found that the bile salts in lactose bile cause an appreciable degree of inhibition in the development of *B. coli*. This inhibition increases with attenuation. Rejuvenation in suitable media, followed by transplanting to lactose bile, will sometimes prove the presence of *B. coli*, usually attenuated, not shown by the lactose bile in direct tests. In actual practice, covering hundreds of samples of Manhattan and Brooklyn waters, the lactose bile, made with the addition of 1 per cent. peptone, has been shown practically to equal the results obtained by rejuvenation in dextrose broth, made with Liebig's extract, followed by transplanting to lactose bile. The authors hold that if dextrose broth is continued in use, it should be made with fresh beef infusion, since it is then more delicate than when made with Liebig's extract. The formula test is of but little practical value and transplantation to lactose bile should be done as soon as gas appears. Gas formation in lactose bile after transplantation from the plain broth or dextrose broth is not always certain, even when *B. coli* is present, on account of interfering growths in the original medium. Lactose bile gives more reliable presumptive tests for *B. coli* than any other known medium, including asculin broth. Other species of bacteria cause much less interference with gas formation of *B. coli* in lactose bile than in any other media. To rejuvenate and transplant seems too laborious and uncertain in routine work. The information gained assists more especially in interpreting the results obtained with lactose bile. Lactose bile makes a distinction between recent and distant contamination, hence better evidence of the actual relative sanitary quality of a water. The use of lactose bile as a step in the separation of *B. typhosus* from water adds yet weightier reasons for its direct employment in the examination of water.

52. Hemophilic Bacillus in Urinary Infections.—In a series of cases of urinary infections, blood media was used by Davis in the routine examination of the urine and other material from the urinary tract with the result that in 3 cases an organism was found which apparently can be cultivated only by this method. The organism is a small non-motile, Gram-negative bacillus whose size varies considerably, but is usually about that of the influenza bacillus. It stains readily with ordinary dyes and is non-acid and non-alcohol fast. With methylen-blue it often stains unevenly, sometimes more deeply at the ends, and again fairly distinct granules may be made out so that it looks not unlike very minute diphtheria bacilli. There is no tendency to form threads or chains, and a characteristic grouping has been made out, though it is common to see the organisms both from urine and from cultures arranged in small irregular clumps consisting of several bacilli. In the urinary sediment they may be seen

clustered about the pus cells, probably having been thus carried in the process of sedimentation. They occur both within and without the leukocytes and at times seem to adhere to epithelial cells. The bacillus does not form spores and does not possess a capsule. Two of the patients had pyuria and the third gave a history of urinary infection some time previously. Two had joint trouble, but there was no evidence to indicate a causal relationship between the bacillus and the joint affection. Davis believes that this bacillus may not be rare and that it has been overlooked because of its hemophilic property.

- 62 Manner of Postgraduate Teaching of Neurology in America. R. E. Castelow, Kansas City.

56. Acute Spreading Peritonitis.—The combination treatment for acute spreading peritonitis, which to Crossen seems best, is as follows: 1. Withhold all food and cathartics by mouth and empty the stomach with a stomach tube. 2. Drain the infected areas with the least possible intraperitoneal disturbance. 3. The Fowler posture. 4. Proctoclysis. 5. Nourishment by rectum.

57. Recognition of Lung Tuberculosis.—Brown says that of all cases of lung tuberculosis which show evidence of active processes, between 95 and 100 per cent. of them can be recognized by the simple methods of physical examination which may be found in any text-book on diagnosis. When possible the conclusions should be supported by laboratory tests.

60. The Advertising Doctor.—Parrish is in favor of educating the public thoroughly in regard to the code of ethics, as it will have a wholesome effect on the profession and at the same time place the profession in a better light before the public.

85. Prevention of Venereal Diseases.—Observation and experimentation have convinced Maus, he declares, that calomel alone (25 per cent), in connection with animal fats, benzoated lard (40 per cent.), and refined suet (30 per cent.), is all that is required to prevent infection from either of the 3 venereal diseases (syphilis, gonorrhea or chancroids), if properly used within reasonable time following sexual contact. The calomel is introduced into the urethra and massage employed for a few moments.

- 88 Red Indican Urine: Its Clinical Significance; the Metchnikoff Theory. A. Bassler, New York City.

88. Red Indican Urine.—From March 1, 1909, to March 1, 1910, Bassler examined 1,371 specimens of urine from patients coming under observation for the first time. Of these, an increased conjugate sulphate partition, represented in the 3 chromogens, was noted 427 times; 171 showed urochrome alone; 67, indican alone; 166 showed urochrome and indican combined; 20, blue and red indican combined, and 3 urohematin alone. The urinary test which he uses is a modification of the Jaffe test, consisting of the addition of an equal part of concentrated hydrochloric acid in the urine (about 5 c.c. of each), then about 2 c.c. of peroxid of hydrogen and about 3 c.c. of chloroform, shaking well, and then centrifuging the whole. This gives the blue and red indican in the chloroform and the urochrome in the supernatant fluid (the red indican and urochrome both being rose-colored). Bassler thinks urohematin is most probably an indoxyl derivative having a clinical significance similar to indican. It is more rarely observed alone than indican, although a purplish color which represents both the blue and the red is a most frequent finding. Red indican urines are often found in extensive disease of the small intestine allowing of resorption, in gastric cancer, and in acute and chronic peritonitis. Like blue indican, it is met with also in ileus and intestinal obstruction, though not so commonly in the malignant and organic strictured states, and in chronic diarrhea. It is present in normal urine in small amounts, and may be demonstrated by shaking the urine with chloroform (about 4 to 1 parts by volume) and decanting it after agitation during several days, when the addition of a drop of concentrated hydrochloric acid to the chloroform will cause the appearance of a rose color—the deeper the color, the greater is the amount of chromogen present. It is probably of albuminoid origin. In the blue indican cases the patients usually present themselves clinically showing depression, relaxation, lowered vitality and persistent anemia. The red indican cases, on the other hand, are more usually of the irritable, anxious, highly neurotic and hysterical types, with good general body and blood conditions, and are not so commonly constipated. Bassler's experience has been that the bacterial and cultural examinations of the feces in the blue and red indican cases show no distinctive differences. Some yield high Gram positive findings, others low. It is almost a daily observation with him that when the proper diet for an indican case has been maintained for a while (essentially proteid free), and the output of indican has been lowered, the individual will develop into a urochrome case for which the diet would be essentially proteid in make-up. Among other things that must be done in the handling of these cases is to put all types on a diet of proper caloric value to meet the weight and work of the individual, and to grade the proteins, protein spares and vegetables to meet the urinary indications. Only in this way can substantial tissue-construction in treatment take place.

2. **Peptic Ulcer and Dilatation of the Stomach.**—An interesting case is cited by Bradshaw, that of a widow, aged 64, who first consulted him in October, 1900. Many years before she had been attended by a well-known physician for hematemesis, and subsequently for mitral regurgitation. When Bradshaw saw her she had gastric pain, there was vomiting, and the stomach was distended. At times the distention was great and was relieved by copious vomitings of watery fluid containing a little blood, sarcinae, and a good deal of free hydrochloric acid. The patient was clearly suffering from temporary complete occlusion of the pylorus. A surgeon who saw her was unwilling to operate on account of her age and the presence of valvular disease. The patient also declined operation, and after one trial of lavage resolutely refused to allow Bradshaw to repeat the process. For some days she was fed entirely by the rectum; even then the stomach continued to fill up with its own secretions. On one occasion spontaneous evacuation through the pylorus and the bowels took place. After some days the power of retaining a little food returned, but any slight increase in the amount was liable to be followed by complete occlusion. A small piece of solid food no bigger than a grain of corn seemed capable of plugging the pylorus; any distention of the stomach caused it to drop and the pyloric end to become kinked.

For 8 years she lived on a pint of fluid and 2 or 3 crumbly bisenits per diem, and in spite of this care had an attack of complete occlusion every 8 or 12 months, each one of which it was thought would prove to be the last. She wore an abdominal belt, which certainly seemed of some service in supporting the stomach. She retained her mental and bodily vigor under this regimen. Two years ago, however, she insisted on consuming meat and vegetables in considerable quantity. An attack of hemorrhage took place. However, she persisted with the new and enlarged dietary, and instead of getting

worse she improved, and after being confined for eight years to a daily allowance of a pint of liquid she found that she was now able to take ordinary food in normal amounts. She began to put on flesh, and for the last two years she has enjoyed good health, takes her meals as do others, and has no return of vomiting or other serious symptoms of gastric trouble. Apparently the disturbance from the taking of solid food two years ago led to the ulceration or stretching of the adhesions that restrained the pylorus.

3. **Migraine Associated with Chlorin Retention.**—This paper deals with records of observations made in a case of long-standing neurasthenia and migraine in a well-preserved man, aged 43. The chief subjective sensations complained of were as follows: 1. Sensations of exaggerated fatigue, which the French express by the word "*courbature*" and the Italians by "*taglia gambe*" (literally, the legs cut from under one). 2. Mental depression of the overwhelming unreasoning kind, so characteristic of neurasthenia. 3. Headaches, lasting sometimes as long as 3 days, accompanied by the usual migraine symptoms; they usually caused insomnia, as he was obliged to sit up in bed to ease the pain; so soon, however, as he slipped down he was awakened with a fresh exacerbation. Depression and fatigue sensations were always associated, analytically, with "Joulie" hypoacidity and more or less decided increase in the "Jacquemet" reaction; on several occasions the tube used in the latter test could be held upside down for as long as 10 seconds before the layer of colloid would allow it to fall. These symptoms were invariably and quickly removed by means of not more than 70 drops of phosphoric acid. On each occasion there was a decided increase in the indican. When he complained of depression alone hypoacidity was not always associated with the symptoms, the urine being occasionally even hyperacid.

In reviewing the facts of this case in order to decide on the details of treatment, Higgins says that it is quite clear that chlorin retention dominates the clinical picture. The therapeutic measures recommended were the following: A Glénard's belt with gentle abdominal exercises and minute care in emptying the colon, if necessary, by enemata; 100 and 150 gm. respectively of grilled lean meat on alternate days, 3 eggs daily, 1 or 2 tablespoonfuls of sour (lactic acid) milk, the remainder of a ration of 80 gm. of proteid to be made up by fish or casein freshly prepared by citric acid. It was particularly insisted on that no proteid should be taken unless it was quite fresh. The vegetable salts of 500 gm. of fresh vegetables were ordered to be taken, with care. They were to be omitted whenever the depression following their ingestion lasted more than an hour or when the headaches recurred. As during the above observations the blood pressure had already risen to 95 mm., only 0.5 gm. of calcium carbonate was given; this was to be increased or diminished as the blood-pressure rose or fell. Two grams of hydrate of magnesium were given, as well as a small ration of iodine in organic combination.

6. **Abuse of Purgatives.**—French shows that it is very important to realize that although it is relatively easy to produce an action of the intestine by means of a purge, this is a very different thing from curing constipation. Purgatives are administered far too indiscriminately, he declares, and a great deal of constipation is increased rather than diminished by them, and it may even actually be produced by them. Just as it is a natural instinct of the brain and body to go to sleep for a regular period in each 24 hours, so it is the natural instinct of the large intestine to empty itself periodically once every day. This regular habit should always be encouraged, and if the bowels opened at the same time each day constipation would be almost non-existent. The difficulty is that, from carelessness and other causes, the action of the bowels may be postponed or responded to irregularly, with the result that, as time goes on, the bowel, brought up irregularly, shows its desire to act irregularly; some days there will be an action, other days not.

Thereupon, those who do not think sufficiently, or do not know what they are doing, at once either take or prescribe some purgative dose, such as castor oil, salt or even calomel, with the result that the contents of the bowel are driven

through, it is true, and there is an apparent relief of the constipation; but the mere fact that there has been an over-action of the bowel to-day makes it all the more likely that there will be no action at all to-morrow and the next day, so that by that time another dose may seem to be required; and so the condition goes on from bad to worse because, instead of encouraging Nature's natural tendency to act once a day, the bowel is forced periodically and left inactive in the intervals. Purgatives should be used with the greatest caution, and a strong dose should never be given when a mild dose would suffice. If the case is merely one of simple constipation it is better to spend some weeks or months trying to coax back the regular habit by getting the patient to try hard at a regular time each day, at the same time giving him more fluids to drink and some foods with an insoluble residue to eat, than to give laxatives at all. Examples of these kinds of foodstuffs are the fiber of green vegetables and fruits, and proportions of husks in porridge and brown bread.

- 12 Simple Method of Removing Sebaceous Cysts. H. Freeth.

9. After-History of Epithelioma of Lip.—This report has been drawn up to afford some ground on which opinion may be based in endeavoring to decide whether the more extensive operation is really desirable. The cases are classified according to the method of operation adopted, the operations for recurrence being classed separately.

1. One operation only; removal of growth on lip by a V-incision; glands not removed; 23 patients, of whom 14 are now well, 4 are known to have died of recurrence, and 2 more have probably done so, and 3 are lost sight of.
2. One operation only; removal of growth on lip and of a palpable gland or glands; 6 patients, of whom 1 is probably cured, 2 died of recurrence, and 2 cannot be traced.
3. Removal of growth on lip and complete clearance of all the submaxillary glands on that side at the same time or soon after, although not palpably enlarged; 3 patients; 2 well, 1 recurred. All cases are rather recent.
4. Recurring cases, patients operated on more than once; 7 patients; 2 are well, 1 has probably had recurrence, 1 died of pneumonia without recurrence, and 3 died of recurrence.
5. Recurring cases in which first operation was performed elsewhere, 6 patients; 2, probably 3, are well, 3 died of recurrence.

It will be seen that of those cases in which no glands were removed at the first appearance 16 ended favorably, and 7 terminated fatally as the result of recurrence. When, however, there were already enlarged glands, though perhaps only one, 1 case resulted favorably, and 5 terminated fatally. There is little doubt, in the author's opinion, that an extensive removal of all the glands, besides those enlarged, is indicated in this latter class.

11. An Immense Renal Calculus.—Ord's case is of great interest for the following reasons: (1) the presence of calculi in both kidneys; (2) the size of the calculus, $3\frac{1}{4}$ inches by 2 inches by 2 inches; (3) the comparatively small amount of discomfort and pain, considering the size and irregularity of the stone; (4) the extremely healthy appearance of both the kidneys at the operations; (5) the separation of the calculus into two large fragments and one small one, articulating by facets, and in a way resembling a knee joint with patella. The joint was movable in a front to back direction, and was evidently flexed whenever the patient bent her back. This capacity for flexion doubtless prevented much of the pain.

12. Removal of Sebaceous Cysts.—In the method employed by Freeth an incision is made, not over the cyst, but through the healthy skin alongside it, parallel to and the same length as the shortest diameter of the cyst. The hypodermic injection of a little eucain solution along the line of the incision is all the anesthetic required. A small blunt hook is then inserted into the incision and is worked round the cyst, tearing through the adhesions of the cyst wall, first on the superficial aspect, as that is where the cyst wall is thinnest and most liable to burst, and then on the deepest aspect, until the cyst is completely separated, when it can easily be delivered by pressure from above, much in the same way as a cataract

is delivered. A dab of collodion on the wound is sufficient dressing. The advantages of this method are said to be:

1. The incision is through healthy skin and is, especially when the cyst is oblong, much shorter than by the usual method.
2. The union is quicker, more satisfactory, and the appearance of the resulting scar much better than that of an incision through the altered skin over the cyst.
3. A minimum amount of anesthetic is used, as only a linear incision is required.
4. In case of cysts situated on the scalp very much less hair need be cut, as all that is required is a single snip of the scissors over the site of the incision.

- 22 Case of Chorio-epithelioma of Uterus. W. E. Wilson.

14. Causation of Infantile Paralysis.—MacKenzie's paper may be summed up as the recognition of the treatment of the muscle as the all-essential in this disease. Instead of waiting for a chance recovery in the anterior cornua, and treating in a perfunctory way the muscles with massage and electricity, it recognizes the fact that every affected muscle will work, provided that a commencement be made from zero. It recognizes that an affected limb will retain its heat, and show little waste, provided that it be rested and worked within physiologic limitations, even without massage and electricity. Work must not be done for the muscle, it must work. Much patience is required; results are slow in arriving in many cases, but these will merit the time and trouble spent.

15. Cervical-Rib.—Bird and Smith review the clinical history of cervical-rib and report 5 cases.

21. Radium.—Lawrence advocates the use of large amounts of radium and increasing the length of time of application, the object being to obtain the selective action of the ultra-penetrating rays of the radium on the cancer cells. He records the results of his experiments with mice, which were extremely satisfactory.

35. Non-Surgical Treatment of Ulcer of the Duodenum.—Herschell is convinced that the chief reason for the want of success so frequently experienced by those attempting to cure a duodenal ulcer by medical means is the half-hearted manner in which the treatment is carried out and the neglect

to make use of the results of recent scientific work. When there is any marked interference to the passage of food along the duodenum, or immediate danger to life from hemorrhage, or perforation, actual or impending, surgical measures are urgently demanded. In their absence one may undertake the medical treatment of a duodenal ulcer with a distinct probability of success, if the patient will cooperate. First, Herschell would eliminate any condition which may possibly account for the deficiency of protecting bodies in the blood. Next, he would remedy the deficiency of antitryptic and antilytic substances in the blood, and reduce the acidity and peptic power of the gastric juice. Then he secures the stomach against distention. One of the chief ways in which a gastroenterostomy conduces to the healing of a duodenal ulcer is by preventing distention of the stomach. One can secure much the same result—(a) by preventing the pyloric spasm by the administration of atropin and alkalies; (b) by giving the food in small amounts at comparatively short intervals; (c) by giving the drink, which should be hot water, not with the meals, but when the stomach is empty. It will then pass quickly out of the stomach, and will incidentally wash and cleanse the surface of the ulcer in the duodenum. Lastly, treat any adhesions.

In order to prevent relapses it is necessary for the patient to observe the following rules for a considerable time after his cure:

1. A proper belt to support the lower abdomen should be constantly worn.
2. A daily dose of olive oil should be taken, fasting every morning, provided that it agrees.
3. A daily dose of normal horse serum should be taken after the principal meal for a month, and then twice a week for another month. In the spring and autumn a dose of serum should be taken twice a week for a month as a prophylactic.
4. All vegetables should be put through a sieve.
5. Preference should be given to white meats, and to boiling or steaming instead of roasting or baking. All made dishes, curry, condiments, pickles and vinegar should be permanently excluded from the diet.
6. The blood should be examined periodically for hemoglobin and steps taken to keep it up to a normal standard.
7. If there has been any melena or occult blood the patient's stools should be examined periodically after a three-days' hemoglobin-free diet.

- 43 *Temperature Curve in Pulmonary Tuberculosis. M. S. Baker.
- 44 Why Has Small-Pox Declined in Prevalence and Fatality? J. Moore.

43. Temperature Curve in Pulmonary Tuberculosis.—Despite the fact that the temperature range has no fixed relation to the morbid changes in the lungs, Baker believes that no other clinical feature offers so reliable a criterion on which to form conclusions as to the patient's future. It is usual to regard the absence of fever as a hopeful sign, although occasionally it will be found that rapidly-advancing cases remain apyrexial throughout. The significance of a subnormal temperature range may best be considered in relation to the circulatory condition present. So long as the pulse remains good, a subnormal oral temperature is not a serious import, but when present in conjunction with a rapid pulse and low intra-arterial pressure it may be regarded as a serious sign. In uncomplicated cases the presence of fever is conclusive evidence of the activity of the disease, and if persistent must influence the prognosis unfavorably. Continuous and remittent fevers are often present in rapidly-advancing cases, and indicate more certainly than any other sign a progressing disease. An intermittent fever of the hectic type is so frequently associated with cavitation that its presence must necessarily darken the outlook, while an intermittent temperature curve whose amplitude of variation is less marked, yields more readily to treatment than continuous or remittent fever. Many observers regard an inverse fever with anxiety, and the sudden appearance of a high inverse range in afebrile cases is specially significant, being often associated with the onset of a miliary infection.

The behavior of the temperature curve under the influence of open-air treatment and rest is a valuable prognostic guide. Cases which exhibit a rapidly subsiding temperature range

under treatment are especially hopeful, while those which show a persistent fever and impaired nutrition under like circumstances hold out little hope of recovery; so long, however, as the nutrition remains good there may eventually occur a subsidence of fever. In charts which show an irregular range where periods of pyrexia occur at intervals a lengthening of the apyrexial periods is to be looked for in favorable cases. A fever suddenly appearing on the second to the fourth day after an hemoptysis, accompanied by dyspnea and cyanosis, and persisting without remission, may always be regarded with the gravest apprehension as indicating the onset of an aspiration-pneumonia, a complication which almost invariably proves fatal.

51. Diphtheritic Paralysis.—The paralysis in the case reported came on about the fifteenth day of mild diphtheria notwithstanding that 70 c.c. of antitoxin had been given in 3 days. The paralysis was evidently the work of endotoxins and further injections of antitoxin were consequently of no avail. The paralysis involved the larynx, heart and lungs but the child, a boy of 10, was finally tided past the danger stage under symptomatic measures and the cure was complete by the end of the third month. He was kept sitting up in bed to prevent suffocation and 2 or 3 mg. of strychnin sulphate was injected daily subcutaneously for 15 days and then changed for another form of strychnin.

52. Ichthyosis and Thyroid Treatment.—Three months of thyroid treatment proved absolutely ineffectual in the 2 typical cases of ichthyosis reported.

57. Clamping and Ligating the Kidney Hilus Instead of the Pedicle in Nephrectomy.—D'Este reports Tansini's successful technique for nephrectomy when there is sclerosis of the hilus and vessels. He applies a clamp to the hilus, including the large vessels and the ureter, and ligates here. Among his 47 operations of the kind he lost only 1 patient and this in 1875, his mortality thus being only 2.12 per cent. This technique also materially shortens the operation.

58. Diabetes in Children.—A similar article by Lauritzen was summarized in THE JOURNAL, August 27, page 813.

59. Characteristic Crying of Infants with Inherited Syphilis.—Sisto remarks that infants cry from hunger or pain and that an inherited syphilitic taint may cause such pain, generally in the region of the epiphysis, that the children scream

or moan incessantly. This constant crying day and night may be the only manifestation of the constitutional syphilis. Under anti-syphilitic treatment the child soon ceases to cry. His statements are based on 8 cases described in detail from his own experience and 5 from Comby's. The children commenced to cry from the second to the fortieth day of life, screaming when they were moved and the crying generally being most severe at night. There was no known history of syphilis in some of the families but the children stopped crying at once under mercurial treatment. Radioscopy generally revealed an osteochondritic process.

65. Stenosis of the Colon from Inflammation Outside.—Küss concludes his long study of what he calls pelvic pericolic stenosis by giving the history in detail of 50 cases, including a number previously unpublished. The inflammation may have originated in the peritoneum, adnexa, or rectum. The strictures in question are characterized by the fact that the mucosa seems to be intact and slides on the subjacent tissues and on the abdominal wall, the latter seeming to form a solid part of the fibrous perirectal mass. The findings suggest cancer except for a history of pain and acute attacks suggesting inflammation in the left half of the abdomen. Hysterectomy, breaking up adhesions, or other suitable intervention is followed as a rule by a complete functional cure; medical measures alone are ineffectual.

66. Treatment of Arterial Aneurysms.—Monod and Vanverts discuss the aneurysms of the various arteries in turn, classifying them thus under 19 heads and reviewing the experiences recorded in the literature with each type, especially the ultimate outcome after the different methods of treatment followed in each.

- 74 *Treatment of Eclampsia. (Zur Kritik des cervikalen Kaiserschnittes.) Richter.

71. Instrumental Dilatation of the Cervix.—At the clinic in charge of Leopold, Bossi's dilator is considered the best instrument for this purpose and it has been used there to start premature spontaneous delivery in 52 cases and in 123 cases as a preliminary to immediate artificial delivery. The indications were mostly eclampsia, nephritis, heart disease, advanced pulmonary tuberculosis or hydramnion. There was no laceration of the cervix in 60 cases, and only such slight injury that there was no bleeding in 35 other cases; tears important enough to require suturing occurred in 28 cases, but the puerperium was febrile in only 8 of these and the fever was briefly transient in all. The dilator must be spread only between the uterine contractions and the instrument should not be used for pluri-parae with cicatricial lesions in the cervix although this was done in several cases in Leopold's clinic without harm. Another important point is to carry the dilatation far enough.

72. Indications for Pubiotomy.—This communication from the Dresden clinic for women, in charge of Leopold, reports the details of 85 cases in which pubiotomy was done. The puerperium was febrile in 48 of the cases and in 20 the condition was serious. Six of the children died possibly in consequence of the operation but none of the mothers. In 10 of the 40 cases in which the women were examined later there were complaints of pain on long standing or walking or lifting. In 21 of the 38 women examined there was a tendency to prolapse of the vagina or uterus or both. In only 6 of the 20 cases in which the women passed through another pregnancy after the pubiotomy was the pelvis found permanently enlarged. The conclusions from the experiences related are that pubiotomy must be restricted to multiparae, to the aseptic cases and to those free from general disease. Pelvis with a true conjugate under 7 cm. should also be excluded from pubiotomy as also all cases in which there is much disproportion between the size of the pelvis and the fetal head.

73. Cesarean Section.—Leopold reports 300 vaginal Cesarean sections and compares the lessons learned from these and other obstetric operations, his final conclusions being that the classic Cesarean section still retains its preeminence, and that every woman with a much contracted pelvis should be sent to an institution at least two weeks before term so that she can be prepared for any necessary operation, infection warded off, and the most propitious operative technic selected.

74. Treatment of Eclampsia According to Stroganoff's "Prophylactic" Method.—Roth reports 31 cases of eclampsia in which Stroganoff's method of treatment was applied. (It was described in THE JOURNAL, July 3, 1909, page 86.) Roth expresses surprise that this technic is not more generally followed as he considers it remarkably effectual and peculiarly adapted for general practice. It must be instituted in time, however; even minutes count in eclampsia. Stroganoff, Roth says, has certainly obtained better results in eclampsia than any other clinician can boast, and the outcome at Leopold's clinic was also unexpectedly favorable as the method had been applied with considerable skepticism. Good results may be anticipated when the physician who first sees the patient begins treatment according to Stroganoff's method and then sends the patient to an institution where it can be continued with expert skill. If general practitioners and the clinics could thus work together, he declares, the treatment of eclampsia would enter on a most promising phase. Others have treated women in eclampsia with morphin and chloral but they gave them only during the convulsions, while Stroganoff keeps the woman constantly under the influence of small doses of the drugs and thus wards off any further attacks. No external influence, noise or light, is allowed to disturb the drowsiness induced by the sedatives. If the woman has to be touched, it is done under 20 drops of chloroform. His plan is to give 0.015 gm. (1/4 grain) morphin at once; in 1 hour 2 gm. (30 grains) chloral; at the third hour, repeat the dose of morphin; at the seventh hour, repeat the dose of chloral; at the thirteenth hour, 1.5 gm. (23 grains) chloral and repeat

this dose at the twenty-first hour. He gives the chloral in a solution of 20 parts chloral hydrate, 20 parts mucilage of acacia and 180 parts distilled water. Only 1 of the 31 women died and autopsy revealed signs of pneumonia in this case, possibly responsible for the fatal outcome.

82. Appendicostomy.—Salis reports 8 cases in which direct medication of the inflamed bowel through the appendix, brought out and sutured to the skin, proved the means of curing obstinate, simple or membranous colitis. Good results were obtained even in the purulent ulcerative form. The technic is so simple that he prefers it to an artificial anus, to resection of the bowel or ileosigmoidostomy, as it answers practically the same purpose while the operation is comparatively an insignificant one. The opening is not large enough, however, he states, in case of mechanical or peritonitic ileus.

84. Implantation of Dead Bone.—Kausch has implanted bone from the cadaver, ivory supports, and dead bone, reporting here 8 cases. The results show that cadaver bones and foreign substances are unsuitable material for implantation, but that bone taken recently from the human body but no longer living can be made to answer the purpose admirably. In one of his cases the tibia was resected, including the periosteum, on account of sarcoma, and a corresponding piece of the tibia from a leg amputated the day before on account of sudden trauma was implanted in its place. The periosteum was scraped off, the epiphyses saved off, the bone marrow scooped out, and a piece 8 cm. (over 3 inches) was implanted in the patient's leg. It was held in place with a long ivory tube at each end, passed into the inner canal in the bone of the graft and stumps. Recurrence of the sarcoma compelled amputation of the leg 266 days later. The implanted bone had become covered with a new growth of periosteum and was being absorbed, its place being taken throughout by new bone tissue. The ivory had been absorbed also but there was no new regeneration of bone in its place.

93. Relations Between Hypersensibility and Immunity.—Friedberger is inclined to regard these as practically identical processes, differing only in degree.

95. To Avoid Accidental Sounds in Ausculting.—Allard distinguishes the sounds due to the muscles or scapula from those originating in the apex by having the patient change the position of arm and shoulder, the change in the sounds then revealing their extraneous nature. The accidental sounds can be excluded by having the patient extend his arm straight, rotate it inward in the shoulder joint and then move the arm backward until the shoulder joint is lowered. With this position there do not seem to be any accidental muscle or scapula sounds; he has noticed moreover that the breathing sounds become more prominent in this position.

101. See abstract 10 in American Current Literature, this issue.

103. Is It Possible for the Hair to Turn White in a Few Hours?—Stieda answers this question in the negative, stating that extensive search on his part has failed to reveal an authentic case of this occurrence. The cases on record are all based on hearsay evidence or the phenomenon is to be attributed to the individual's not being able or forgetting to use the customary hair-dye. A patient of Behrend's suffered from headache and he advised the man to give up the use of his hair-dye, which was probably responsible for the headaches. The man did so and explained to his friends that the sudden change of his black locks to white was the result of business worries. Stieda also knows personally of a case in which a dark-haired man was taken to prison and when discharged after a few days his hair was white, but simply because he had not taken his hair-dye with him to prison.

105. Origin and Treatment of Scoliosis.—Hoffmann lays great stress on prevention of scoliosis, declaring that once established the treatment is tedious and not very encouraging. He ascribes the development of the curvature to the fact that the child loses the instinctive sense for the correct attitude of the body owing to strain on the muscles from certain attitudes at school work. When examined the child seems to be scoliotic when in reality it merely assumes a scoliotic attitude from disturbances in the sense of muscular balance. Sitting without a support for the back aids in fatiguing the muscles and to rest them the child stoops over or twists around or slides down in its seat. Girls' muscles do not get so much exercise as boys' and consequently these faulty attitudes are more common among them. When this scoliotic attitude once becomes habitual, the child is unable to stand up straight even when it tries to do so, and it has to be taught anew the sense of muscular balance in the spine. This can be done by training, the physician saying, "Chest out; draw in your abdomen; throw your head back; hold your right shoulder lower, etc.," aiding these

commands at first with manual pressure, but later relying on the commands alone and shortening them, until when the child is told to stand erect it assumes automatically the proper position. It may be wise to teach a rather over-corrected attitude at first. This training of the muscles is supplemented with gymnastics to strengthen the back muscles, and he instructs the mothers to carry on the training under occasional supervision by the physician. The measures must be individualized to each case, he says, possibly including a slanting seat in school and higher sole on one side. Creeping exercises, etc., may be useful in advanced stages but he prefers exercises erect, as the aim is to teach the child to stand and sit straight.

108. Superheated Air in After-Treatment of Laparotomized Patients.—Strempel is enthusiastic over the way in which peristalsis is stimulated after a laparotomy by applying heat to the abdomen, either in the form of the hot-air box or an incandescent electric-light box. He has used the latter exclusively as he happened to have a contrivance of the kind on hand. In his 141 cases flatus passed generally in from 18 to 24 hours, seldom as late as 48 hours. Another advantage of the method is that the patients are thoroughly warmed by it, counteracting the tendency to chilling during the operation. The temperature in his box can never get over 55 C., so that the box does not require very close supervision. He applies it for an hour and a half at a time, with intervals of 3 hours, and keeps this up night and day until all danger of intestinal paralysis is past. He has never witnessed any injurious effect on the heart and vessels although he has kept close watch for any tendency in this direction. No adjuvant measures were needed in any instance as the heat answered all purposes, except in a few cases a pint of water was injected to soften hard feces, or an intestinal tube was inserted to promote passage of flatus when the patients were too weak to strain. The only possible mishap from this method of after-treatment is that very restless patients on arousing from the effects of their anesthetic are liable to scorch the skin against the electric lights. The heat not only stimulates peristalsis but seems to promote absorption and prevent formation of adhesions while it seems to attenuate the virulence of bacteria in the region.

110. Closing the Stump of the Severed Intestine by Rolling it Over.—The long narrow forceps with which the stump of the intestine is clamped are rolled up on the intestine for two or three turns. The last turn is sutured to the body of the intestine and the forceps are then withdrawn. The lumen is thus more effectually closed than by the ordinary technique. Klapp declares, while the procedure is simple and neat.

118 Hypothyroidism in Children.—Stoeltzner remarks that myxedema is not often correctly diagnosed; the children are generally treated for years on the mistaken assumption of rachitis. As a prospect of a cure grows less and less with the duration of the myxedema, this failure to recognize it early may have disastrous consequences. The rudimentary forms are particularly liable to escape recognition, while thyroid treatment in time is almost a certain cure. In a case of this kind, a boy of 6 had not grown in the last 2 years but seemed otherwise normal, although not particularly bright. Under cautious thyroid treatment by the end of 18 months he had grown 11 cm., nearly 4½ inches. In 2 other cases the myxedema developed after severe measles or mumps, with acute thyroiditis in the latter case. The thyroid treatment ordered was soon abandoned by the family and the child developed pronounced myxedema, but after 2 years it spontaneously subsided. In a fourth case the myxedema developed after a severe fall over a banister, the throat in front bleeding from the injury. The hypothyroidism in this case was evidently of traumatic origin, the first case of the kind on record, he believes. In this case also thyroid treatment promptly cured the child. In conclusion Stoeltzner suggests that the "pasty" children, fat, pale and flabby, may be suffering from hypothyroidism and require thyroid treatment. Overfeeding of children with this tendency to hypothyroidism seems to entail lymphatic enlargement.

119 Lime and a Tendency to Convulsions.—Rosenstern is convinced that the research to date has established the fact that the calcium ions are highly important for the regulation of the phenomena of movements and of nerve stimulation. His own experience confirms the assumption that a deficient proportion of lime in the food may entail nervous over-excitability while he found that the excitability was materially reduced in 15 out of 20 infants with pronounced spasmophilia after ingestion of 100 c.c. of a 3 per cent. solution of calcium chloride (CaCl₂). The cathode opening contraction, the facialis phenomenon and Trousseau's sign all showed the marked influence of the single dose of lime; a solution of sodium chloride, on the other hand, seemed to have a contrary action. No injurious by-effects were observed from the single dose of lime, and Rosenstern thinks that his experience deserves attention as a means of treating an acute attack of threatening convulsions in a child. The infants to whom he gave the lime were all between 4 and 12 months old and most were inclined to dyspeptic disturbances besides the spasmophilic tendency.

120 Stenosis of the Pylorus in Infants.—Berend writes from Budapest to describe his experience with spastic stenosis of the pylorus in his own 2 children. The cases were distinguished further by the intensity of the syndrome. In his first child the weight dropped from 3,050 gm. at birth to 1,800 in less than 3 weeks, and operative treatment became necessary. Loret's divulsion was done; the hard contracted pylorus relaxed in the surgeon's hand during the operation but it was still unusually thick although there was no trace of organic stenosis. The explosive vomiting continued as severe as before, the divulsion having evidently done no good, and the child growing constantly worse, the pylorus was incised and a Nélaton catheter, No. 7, French, was introduced through the mouth and passed through the pylorus into the duodenum. By this means it proved possible to feed the infant and recovery soon followed, all trouble being over by the time the child was 6 weeks old; it is now 3½ years old and perfectly healthy. The disturbances in his second child were not so severe; the pylorus was never palpable and the syndrome disappeared under medical measures alone. The first symptoms in both cases were the uneasiness in nursing so that the children were unable to empty the breast, and the protruding stomach, this protrusion of the stomach region and difficulty in nursing sustaining the assumption that

the spasm of the pylorus is the primary disturbance. Peristalsis in the stomach was noticed 4 days later and the tumor, the size of a hazel-nut, in the pylorus region by the end of the week. He recognized the true trouble from the start and kept a detailed record of all the data, especially the amount of fluid ingested and vomited each day. Notwithstanding the severe derangement from the pylorospasm, the organism tenaciously maintained its normal water balance. He is inclined to ascribe the whole trouble to a lack of balance between the musculature of the antrum and the musculature of the fundus of the stomach; when the innervation of both becomes normal then all disturbances from this source cease. At birth there is neither spasmodic contraction nor hypertrophy of the pylorus, merely the predisposition. Winternitz discusses the cases from the surgical standpoint, calling attention to the extreme retraction of the muscular pyloric ring after the lengthwise incision, indicating excessive tonicity in the muscle. The pylorus was incised over the tube introduced from the mouth; this allowed ample nourishment from the first and the child began to gain at once. The retention pylorus catheter has proved successful in other cases in his hands, but he warns that it should not be left *in situ* longer than 2 days.

123. Ehrlich's "606" in Treatment of Syphilis.—Hoffmann states that recurrences have been observed in large numbers of cases of syphilis after treatment with "606" in the customary dosage, and that by-effects have accompanied the use of the remedy to such an extent as to invalidate the claim made for the "606" that it is entirely harmless. In his experience with it by-effects were noticed only when the drug was in an acid solution, while they were absent when a neutral solution was used. The remedy does not certainly kill all the spirochetes as claimed, he says, as he was able in one case to demonstrate the presence of lively spirochetes in lesions on the genitals and tonsils a week after the injection of "606." In the case of a boy of 15 with syphilitic ozena from inherited taint, the improvement at once under the "606" was remarkable. In a case of ulcerated gummas in the mouth, throat and testicles of a man of 40, high fever, pulse of 140 and dyspnea followed the injection of the "606," other signs indicating central pneumonia of embolic origin and secondary pleurisy with extreme weakness of the heart. He ascribes this syndrome to dislodgement of a thrombus in the gluteal muscle following injection of a very acid solution; nothing about the syndrome suggested local infection of the site of the injection. In 2 other cases there was considerable disturbance of the heart action, the pulse running up to 120 and 160, the area of dullness spreading toward the right with accentuation of the second sound. These findings persisted for a few days and then gradually subsided. In another case there was a slight albuminuria. No visual disturbances were ever observed. He knows of a case in a Bonn institution in which the patient died suddenly the night after the injection. Ehrlich adds the details of this last fatal case as he has obtained them by telegraph. The patient, he says, was a woman of 33 with syphilitic apoplexy, paresis of the legs, tachycardia, difficulty in swallowing and accelerated breathing. The conditions in this case should have forbidden the use of the "606," he declares, as he has expressly rejected all responsibility when the remedy is given to other than those healthy except for the syphilis, and the organs sound. He also excludes the metasymphilitic diseases from treatment with

"606." He reaffirms that given in the right way and with proper indications the remedy is free from dangers and does not induce any appreciable by-effects. Ehrlich has the records now of over 3,000 cases.

133. Operability of Recurrence After Removal of Uterine Cancer.—Hoehne makes a point of keeping patients under supervision after he has operated on them for uterine cancer. He tells them to return to be examined at certain intervals and keeps a record of the dates, sending them a notice if they fail to present themselves as ordered; nothing should be allowed to interfere with this systematic reexamination. In 2 cases he was able by this means to discover recurrence in an early stage and successfully remove it, before the patients had the least suspicion that anything was wrong with them again, their general health being excellent. The after-examinations are always made with the greatest care and on discovery of the slightest suspicious lump the patient is taken into the hospital for 2 weeks' control. If the lump grows any larger during this time it is assumed to be malignant and is removed, but if it does not grow or subsides, the patient is dismissed and systematically reexamined at intervals. Prophylaxis of recurrences in this way is much more promising, he remarks, than the efforts to have primary cancer diagnosed earlier. The surgeon can thus root out recurrences on their first appearance. He describes a case in which what was supposed to be a nodular recurrence, not discovered until quite large, proved to be merely thick indurated cicatricial changes in the tissues. In another case what seemed to be merely an inflammatory infiltration proved to be a malignant recurrence extending diffusely through the region. Another case demonstrates the danger of thrombosis of the iliac veins following carcinomatous involvement of the vessel wall. It might be possible in such cases, he suggests, to prevent trouble from this source by ligating the main iliac vein before resecting the cancerous glands encroaching on the vein.

137. Prophylaxis of Habitual Death of the Fetus.—Anomalies or disease of the placenta or changes resulting from the influence of chronic nephritis or nutritional disturbances in the endometrium may be responsible for the death of the

fetus in repeated pregnancies. In a case reported by von Franqué there were numerous patches of fibrous degeneration in the placenta; the patient was a woman of 38 with chronic nephritis and the fetus had died just before term in 3 previous pregnancies. She was kept under constant supervision during the 2 weeks before term and after a week the fetal heart sounds were found to be growing weaker, so he punctured the membranes and followed this in less than an hour with vaginal Cesarean section. The child was of normal size but weighed only 2,850 gm., evidently having suffered from insufficient nourishment, but has since developed normally. In another case, he delivered with the inflatable bag under much the same conditions. The pathologic findings in the placenta were not so pronounced in this case, but there was evidently a reaction to some irritating process. He declares that artificial premature delivery just before term as indications arise in these cases of habitual fetal mortality is a thoroughly scientific procedure, most gratifying in its outcome.

138. Treatment of Sciatica with Epidural Injections.—Mum applied the perineural technic, that is, injection around the nerve of an anesthetic or saline solution, in 25 cases of sciatica and the results were generally good. In 3 cases, however, no effect was obtained, and he has since used Cathelin's epidural technic and found it even more satisfactory. It was described at length in *THE JOURNAL*, July 13, 1901, page 150. The fluid is injected into the spinal canal through the lower median sacral foramen, the needle having to pierce only the sacrococcygeal ligament. The ligament once pierced, the needle is turned to point toward the cauda equina above. After injection of from 5 to 10 c.c. of salt solution, improvement of the sciatica is evident at once, very rarely the delay is 24 hours after the injection. In a few persistent cases he had to repeat the injection 3 or 5 times at intervals of 2 or 3 days before a complete cure was realized. The effects were always at least as good and as permanent as with the perineural injections, while the epidural technic is not painful, he says, and has never induced fever or untoward by-effects in the thousands of cases in which it has been used to date. This cannot be said of the perineural technic; he observed peroneus paresis in 2 cases after the perineural injections and others have reported similar experiences. Another advantage of the epidural technic is that it acts on other nerve tracts as well as on the sciatic; the single injection banishes pain in the sacrum and femoral nerve, while with the perineural technic each nerve has to be treated separately. The epidural injections have also been successfully applied to relieve the pain from compression of nerve roots by a cancer in the spine, to relieve the gastric and bladder crises in tabes and in lead colic and to cure nocturnal enuresis.

145. Nephritis with Exophthalmic Goiter.—Graupner relates a number of experiences and arguments which demonstrate that hyperplasia of near lymphatic organs is liable to develop in consequence of the progressive hyperthyroidism and thyroid intoxication, this hyperplasia being most evident in the thymus, lymph glands, in heteroplastic lymphomas in the thyroid itself or in the spleen and bone marrow. There may be a toxic nephritis characterized by necrosis of the epithelium; its development is favored by operative intervention on the thyroid as in the 2 cases reported in detail in which the patients succumbed in 18 and 26 hours after the operation. There was pronounced status lymphaticus in both cases and recent destructive nephritis.

162 Curative Action of Laparotomy in Peritoneal Tuberculosis. Heumann states that 36 women with tuberculous peritonitis have been laparotomized at Küstner's clinic in the 10 years ending in 1908. All were much improved or cured by the operation, and 15 have been recently reexamined. Fully 54 per cent seem to be in perfect health at present, good testimony as to the curative value of a laparotomy in these cases. In 2 other cases Heumann had occasion to laparotomize women who had been operated on elsewhere years before for peritoneal tuberculosis, and he found that the tuberculous lesions had completely healed. The aspect was the same as that in guinea-pigs after complete recovery from experimental tuberculous peritonitis. The peritonitis in his cases was of the serous type and the laparotomy was made as soon as the trouble was diagnosed. Concomitant lung lesions seemed to be benefited by the operation at the same time as the peritoneal. The abdomen was merely opened and the ascites evacuated; no attempt was made to rinse out the abdominal cavity and the adnexa were left undisturbed, even when there was reason to suspect a tuberculous lesion in them. One of the women has passed through a normal pregnancy since. He lays great stress on his routine practice of systematic tuberculin treatment commenced the seventh day after the laparotomy, the course being kept up by the family physician after the patients leave the hospital.

165 Vaginal Racemose Sarcoma in a Child.—Knoop's little patient was a girl of 3 and the racemose sarcoma recurred in 6 months and again 3 months after the second operation, after which the child died. He reviews the similar cases on record, insisting that discovery of heterologous elements even in an apparently simple vaginal polyp in a child should compel removal of the entire genital apparatus by Wertheim's carcinoma technic, even in very young children. Malignant growth in the child vagina are of a different nature from those in adults and require still more energetic measures.

- 172 Technik für Laminektomie für Treatment of Spinal Cord Tumors. (Zur Technik der Laminektomie in der Behandlung von Rückenmarkstumoren.) Röpke.

171. Treatment of Exstrophy of the Bladder.—Makkas cut off the lower part of the cecum, making a closed bag of it, in which he implanted the ureters. He then drew the appendix out through the skin below to serve as an outlet for the urine accumulating from the ureters in the new reservoir formed by the cecum bag. The patient was a girl of 12 with typical exstrophy of the bladder and atresia of the vagina. The capacity of the new reservoir is over 300 c.c. and the child wears a retention catheter to date. The cecum was prepared for exclusion and implantation of the ureters by 10 days of sterilization. This technic avoids the great drawback of the Maydl technic, namely, mixture of feces with the urine, and thus all danger of ascending infection of the kidneys is obviated. With perfected technic, he adds, it may be possible to insure continence without the necessity for a retention catheter. The article is illustrated.

- 174 *Recurring Extra-Uterine Pregnancy. (Wiederholte Extra-uterin-Gravidität.) G. Siefert.

174. Repeated Extra-Uterine Pregnancy.—Siefert has had a second extra-uterine pregnancy occur in 1 out of his 25 cases during the last 10 years and a second case is suspicious. This percentage of recurring ectopic pregnancies and the similar small numbers encountered by others, render it unnecessary to take measures to prevent future pregnancies when operating for extra-uterine pregnancy, which some have advocated. In 3 of his 25 cases the women have passed through normal pregnancies and deliveries since the operation for the extra-uterine pregnancy.

179. Pellagra.—Campana protests against the assumption that there is only one single cause for pellagra.

178. Laparotomy for Peritoneal Tuberculosis.—Gangitano calls attention to the transient albuminuria which he noted in all the cases in which recovery followed the laparotomy, that is, in 7 out of the 12 cases of tuberculous peritonitis in which operative treatment was tried. In the 5 other cases the effusion returned, notwithstanding a second laparotomy in 2 cases. It seems evident that when the laparotomy modifies conditions to such an extent as to lead to a cure, albumin appears in the urine. The proportion was never large, amounting to 0.5 per thousand in only 2 of the cases. His patients were women and girls, between 14 and 49, and the tuberculous peritonitis was of from 4 months to 2 years' duration.

He merely opened the abdomen and wiped the peritoneum dry with sponges, not flushing it, following the laparotomy with injections of iodine-iodid solution according to Durante's technic, and 7 of the 12 patients have completely recovered.

180. Influence of Fatigue on Processes of Infection and Immunity.—De Sandro reports extensive research on dogs, rabbits and guinea-pigs injected with typhoid toxins after severe muscular strain. Under the influence of the chemical changes induced by the physical strain, the nervous exhaustion, fatigue of the heart and disturbances in the blood production, the defensive powers were evidently much weakened; phagocytosis was reduced and also the chemotactic power of the cells, the bacteriolysins, antitoxins, agglutinins and opsonins showing a marked falling off.

182. Anesthesia of the Eyeball in Nervous and Mental Disease.—Vidoni and Gatti pressed the eyeball down on the floor of the orbit seeking for a sign of organic nervous disease and found, in fact, that the pain which this induces in normal conditions was absent in the 2 cases of tabes in their series of 88 patients with various nervous or mental affections. The anesthesia of the eyeball was also pronounced in 2 insane adults. The anesthesia is probably due to some lesion in the sympathetic nervous system, they say, adding that it may aid in the early differentiation of tabes.

A CASE OF DIFFUSE, PURULENT, VENTRICULO-SEPTAL MYOCARDITIS WITH ADAMS-STOKES' SYNDROME*

HARVEY G. BECK, M.D.

AND

WILLIAM ROYAL STOKES, M.D.

BALTIMORE

The subject of suppurative myocarditis has received some attention from ancient writers, since Whittaker¹ states that Galen described this malady in gladiators and Benevenus and Bonetus have also described abscesses in the walls of the heart. Later, Laennec and Meckel cited similar cases.

These cases of suppurative myocarditis are called "myocarditis purulenta" by Aschoff,² who shows that they are usually produced by ulcerative endocarditis, intracardiac thrombosis, pericarditis and septic infarction and abscess formation in cases of general pyemia. It will be seen that these purulent infiltrations or abscesses in the heart muscle are secondary processes caused by an antecedent infection. The case we shall later describe is a primary condition and cannot, therefore, be compared to the above mentioned processes.

The condition known as acute interstitial myocarditis, which follows such infectious diseases as diphtheria, scarlet fever and rheumatism, first described by von Haven,³ also differs from our case, since it is characterized by an infiltration of lymphocytes, plasma cells and fibroblasts, while the polymorphonuclear leukocytes are absent.

Before describing our case in detail we wish to cite a case of acute purulent interstitial myocarditis following subacute rheumatism which was described by Freund⁴ in 1898.

This patient had a frequent pulse, a rise of temperature, precordial pain and delirium. The autopsy showed a flabby heart containing yellow dots and lines, and the microscopic examination revealed a diffuse inflammation with polymorphonuclear leukocytes combined with scattered hemorrhages. The blood-vessels were filled with leukocytes and the small veins contained thrombi. The muscle fibers contained vacuoles; the nuclei were elongated, thickened, fragmented and at times absent, and the cross-striations were often obscure, while the individual fibrils seemed separated one from another. Toward the endocardium they showed fatty degeneration.

The above case is the only one we have been able to find in literature of a true, diffuse, interstitial, purulent myocarditis, but we have collected a few typical instances of circumscribed abscess formation in the heart muscles. Carnas⁵ states that abscesses of the walls of the heart have been most frequently observed in pyemia and ulcerative endocarditis. In certain cases there are remissions followed by relapse which give a subacute or chronic character to the disease. Laking⁶ describes a case of many months' illness with sudden death, which showed two long-standing abscesses in the apex of the left ventricle, and Roth⁷ has shown that these abscesses may undergo calcareous transformation. Chance⁸ and Howitt⁹ both report abscesses of the heart in children, and nine out of ten cases occur before the thirtieth year. Formad¹⁰ reported a case of abscess of the heart about the size of a large bean with accompanying purulent myocarditis, and it is interesting to note that this condition may develop from a circumscribed abscess. Banks¹¹ also has described an abscess the size of a pigeon's egg in the left ventricle.

Abscess of the heart follows pyemia or septic endocarditis and is characterized by angina-like symptoms, dyspnea, gallop rhythm, dicrotic pulse and temperature, and Loin¹² states that this condition may be distinguished from septic endocarditis by a more rapid pulse in the former condition.

The association of heart-block with infectious diseases has recently been established. The few cases thus far reported have been reviewed by Peabody,¹³ who reports an additional case. Some of the patients recovered. Autopsies have revealed various lesions of the bundle of His, such as anemic necrosis of the muscular septum in the region of the bundle, cellular infiltration, fibrous degeneration with a calcareous nodule pressing on the bundle; and James¹⁴ has reported a case in which the bundle of His was completely destroyed by an ulcer in the interventricular septum due to a streptococcus septicaemia.

Other conditions which may produce heart-block and Adams-Stokes' syndrome are syphilitic gummata and scar formation, calcareous deposits, fatty infiltration, septic and benign infarction and fibrous tumor of the

bundle of His, as we have already described in a former article.¹⁵

We regret that we were unable to obtain any pulse tracings in the case the report of which follows, but the patient was under observation only for several days in the hospital, during which time the sphygmograph was being repaired. Nevertheless, we are convinced that he suffered from heart-block with Adams-Stokes' syndrome. The case is unique because of its association with the rare condition of primary purulent myocarditis.

CASE REPORT

CLINICAL HISTORY

Patient.—J. C., a man aged 67, by occupation a street-cleaner. His history is unimportant. In early childhood he had measles, scarlet fever and mumps. Apart from these maladies he enjoyed remarkably good health until his thirtieth year, when he contracted syphilis. He developed the usual characteristic secondary symptoms, for which he received several months' treatment. He was always employed at heavy, laborious work. In his earlier days he was strongly addicted to the use of alcohol, mostly in the form of whisky. For the past twenty-five years he drank more moderately.

Present Illness.—He continued in good health until seven months before his admission to the Mercy Hospital. At this time he began to have vertigo and syncope with epileptiform seizures. These attacks came on abruptly, frequently without premonition, at other times with a brief aura, consisting of a sense of smothering, scotoma and tinnitus aurium. The patient sank rapidly into a state of semiconsciousness, which was followed by clonic spasms of the facial muscles on the right side and tingling and formication in both upper extremities. Other associated symptoms were vasomotor disturbance, oppressive sensation in the epigastrium, with pain which radiated to both arms, and intense dyspnea. The entire seizure lasted only a few minutes. These attacks came on very frequently. They were usually single, but sometimes five or six followed in close succession; excitement or physical exertion had a tendency to produce them. For this reason the patient had been unable to follow his vocation for the past seven months. Three months after the onset of the attacks a cough developed, which was accompanied with a slight expectoration. Dyspnea on slight exertion became an annoying symptom. Later he noticed enlargement of the veins in his legs, which subsequently became varicose. There was no edema. He had a constant feeling of pressure in his epigastrium and dyspeptic symptoms were marked. On March 25, 1910, on the advice of his physician, Dr. C. F. Blake, he was sent to the hospital.

Physical Examination.—This revealed the following condition: The patient looks fairly robust, is well developed and in a good state of nutrition. Mentally he is apathetic, inclined to stupor and talks incoherently, but, when aroused he appears nervous and apprehensive and responds readily to inquiries in a perfectly rational manner. The face is pale, the lips slightly cyanosed and the conjunctivæ anemic and injected. The pupils are equal and react sluggishly. The tongue is coated and flabby with marginal indentation. The mucous membrane of the tongue and buccal cavity show a slight degree of cyanosis. There is a small patch of alopecia of the scalp, and the hair and eyebrows come out readily. The jugular bulbs and the superficial veins of the neck are distended and pulsate. The chest is somewhat emphysematous in type. Breathing is irregular and, at times, Cheyne-Stokes in character. Percussion of the lungs shows hyperresonance over the anterior and lateral aspects of the chest and over the upper half posteriorly. The bases of both right and left lung are moderately dull. Fremitus is generally decreased. On auscultation emphysematous breathing is heard over the entire chest and a few dry scattered râles are heard.

Heart: The maximum apex impulse is in the fifth interspace at the mammillary line. There are no abnormal areas of pulsation. Relative cardiac dullness extends 1.5 cm. to right

of the right sternal border and the distance from the mid-sternal to the left border at the apex measures 9 cm. Dullness begins above at the lower border of the second rib. There are no cardiac murmurs at the apex; both sounds are clear and distinct. The first sound, however, is not entirely normal, as it lacks the so-called booming quality which is a distinctive feature of the mitral systolic sound. The aortic and pulmonary first sounds are almost inaudible. A reduplication of the second sound is heard at the aortic and pulmonary areas, and also at an area corresponding to the junction of the fourth interspace and left sternal border. Bradycardia is pronounced and the cardiac rhythm is fairly good. There are from 44 to 46 apex-beats per minute, while there are from 88 to 94 jugular pulsations, denoting practically a 2 to 1 rhythm. The radial pulse is likewise slow (46 per minute), but the rhythm is good and pressure is minus. The ratio between the auricular and ventricular systole is disturbed when the patient exercises.

The blood-vessels are somewhat thickened, but no more so than one would expect to find in a man of the patient's age. With the exception of double inguinal hernias the abdominal examination is negative. The superficial veins of the lower extremities are engorged. Reflexes are not disturbed. There is a slight enlargement of the cervical and inguinal glands.

Urine: Specific gravity, 1.013; traces of albumin; otherwise negative.

Course of Disease.—March 28: The patient had several seizures during the night, following each other in close succession, and to-day he appears exhausted and drowsy. He has Cheyne-Stokes breathing and voids large quantities of urine.

March 29: Slept well during night and shows a general condition of improvement. Radial pulse is fairly regular but slow. Jugular pulse well marked. Two pulsations occur to one radial.

March 30: Radial pulse, 43; jugular, 86. Forced exercise in bed produced an acceleration of the venous pulse to 98, but had no effect on the radial pulse. The following records taken during the day show the relation between the radial and jugular pulses:

Time.	Radial.	Jugular.	Time.	Radial.	Jugular.
9:30 a. m.	48	99	12:00 m.	46	94
10:00 a. m.	46	84	12:30 p. m.	44	90
10:30 a. m.	50	104	1:00 p. m.	48	96
11:00 a. m.	48	98	1:30 p. m.	42	90
11:30 a. m.	52	90	2:00 p. m.	50	98

March 31: Patient felt comfortable during the early part of the night, but later in the night he ventured out of bed and was found in the toilet with an acute paroxysm. He had another paroxysm shortly after returning to bed, from which he quickly recovered. Several hours later he was found dead in bed.

During his entire stay in the hospital the patient's temperature was normal.

GENERAL AUTOPSY REPORT

Body Section.—Lungs show some edema and congestion. Pericardial sac filled with a bloody fluid. Heart somewhat enlarged. Arteries show some sclerosis. Liver about normal in size, but showed chronic passive congestion. Spleen normal. Right kidney much enlarged and several small cysts on its surface filled with a watery fluid. Left kidney enlarged and both showed chronic nephritis. Stomach showed marked congestion and acute gastritis.

Owing to an unfortunate accident no microscopic sections were made from the viscera, other than the heart, but it may be taken for granted that there was no acute purulent condition present and that the sections would have shown only a chronic nephritis and an acute congestion of the gastric mucous membrane.

Bacteriologic Examination.—No cultures were made, but stained specimens showed a few pneumococci in the purulent areas of the heart muscle.

EXAMINATION OF HEART

The heart is somewhat enlarged, weighing 450 gm. The measurements are as follows: Thickness of left ventricle midway 18 mm.; length of left ventricle 8.5 cm.; aorta, just above valves 8 cm. in circumference; interventricular septum 9 mm.

15. Beck and Stokes: A Clinical and Pathologic Study of a Case of Adams-Stokes Disease. Arch. Int. Med., 1908, li, 277.

thick. Right side of heart: right ventricle 8 mm. thick; length of right ventricle 8 cm.; pulmonary artery just above valve 5.5 cm.

The papillary muscles of the right and left ventricles are flattened. The heart muscle is reddish brown in color, and, on cutting through the interventricular septum, near the auriculo-ventricular septum, fine yellowish streaks can be seen. On making a flat section of the muscle of the left ventricle opposite the interventricular septum, small grayish streaks and small reddish dots are apparent in the muscular substance which has been laid open. The valves are normal. The aorta contains a few small yellowish plaques just around the entrance of both coronary arteries, and there are numerous smaller plaques scattered over the intima of the rest of the aorta.

Fig. 1.—Heart, showing the situation of the various blocks from which the sections were made. These are numbered as in the text. These blocks of tissue were cut out of the heart in order to obtain cross-sections of the bundle of His.

Coronary Arteries.—Both coronary arteries were dissected out to the ramification of their finest branches, and the general condition is as follows:

Left Coronary Artery: The main artery, the left descending branch and the circular branch all contain numerous bulbous thickenings, giving the artery an irregular, beaded or nodular appearance. To the touch, the entire artery is much firmer and harder than normal, and the irregular miniature sausage-shaped nodules have the feel of hard bony tubes. A fine probe measuring 1 mm. in thickness can be passed through the circular branch and also through the descending branch to a distance of 6 cm., but the lumen is evidently narrowed, as the probe passes with difficulty. On opening the artery, the intima is seen to contain numerous irregular yellowish elevations, most of which contain a soft pultaceous yellow material, or a much firmer calcareous deposit forming thick plates.

Right Coronary Artery: This artery does not show the same nodular condition, but presents rather a general indurated, cord-like, leathery feeling. On opening up the artery, there are a few small yellowish plaques containing a soft, pultaceous, yellow, cheese-like material, but there are no calcareous deposits. The intima seems universally thickened, presenting a firm, tough, thickened tissue. A probe 1 mm. in thickness passes 4 cm. through the main artery, where it is abruptly stopped by an adherent thrombus which extends for a distance of 3 cm. in the descending branch supplying the right ventricle.

Histopathology.—Before describing the microscopic changes present in the heart, it is necessary to describe the situation of the various blocks of tissue from which the sections are made, and this can best be explained by referring to the photograph of the heart which is seen in Figure 1.

Section 1 was made from a block of tissue bounded to the left by the endocardium of the left ventricle, to the right by the endocardium of the right ventricle, and above and below, by the fibromuscular wall of the auricular septum. The section, therefore, passes from above downward directly through the center of the fossa ovalis, and includes the muscular structure of the auricular septum for a considerable distance below the fossa. It, therefore, would show a cross-section of any of the rootlets of the bundle of His, taking their origin from the region of the septum. The area formerly occupied by this block of tissue is indicated by the number 1 which will be found within the limits of the first set of white lines.

Sections 2, 3, 4, and 5, were made from blocks of tissue which include the horizontal course of the bundle of His, showing, therefore, cross-sections of the bundle. They form triangles whose apices are represented by a point just above the auriculoventricular fibrous ring, and whose sides are formed by the endocardium of the right and left ventricles. The bases are formed by lines passing from the left to the right ventricle directly through the interventricular septum. The situation of these blocks is indicated in Figure 1 by the numbers mentioned above, and their distal planes are designated by the white lines.

Sections 6, 7, 8 and 9 are made from blocks which follow a line perpendicular to the apex, which begins at the base of the last section, and ends at the apex. These blocks pursue the general course of the two branches of the bundle of His for the right and left ventricle, and the sections, therefore, show these branches in an oblique or horizontal plane. The white lines show the distal limits of each block, while the numbers show the situation of these blocks.

Sections 10, 11, 12 and 13 are taken from blocks which pursue a gentle curve around the very limits of the auriculo-

Fig. 2.—Cross-section of the bundle of His at A, in which there were numerous hemorrhages. The auricular septum is above and the ventricular septum below, the bundle running in a groove between its two septa. The thick bundle passing down to the left is the endocardium for the right ventricle and the thinner branch nearer the endocardium is the branch for the left ventricle.

ventricular septum adjacent to the apex, and they end at the very tip of the apex of the heart. They are numbered by black figures, and the black lines indicate the limits of each block of tissue.

Microscopic Examination.—No. 1: This section, passing through the muscles of the auricular septum, the fossa ovalis and the lower portion of the auricular wall, shows a few strands of the bundle of His, taking their origin from the thin wall of the fossa. The nuclei are larger than the rest of the heart muscle, and the muscle fibers are separated at

surrounded by a connective tissue containing many fibroblasts, lymphocytes and a few polynuclear leukocytes.

No. 2: This is a section through the proximal end of Segment 2, showing the auricular septum, the ventricular septum and the auriculoventricular groove containing the bundle of His. The bundle of His and the connective tissue around it are infiltrated by many polynuclear leukocytes. The muscular structure of the ventricular septum, especially that near the endocardium of both ventricles, presents a remarkable appearance. There is a diffuse purulent infiltration of the muscles separating individual fibers or groups of fibers. Many of the fibers show necrosis, and there are also groups of leukocytes which show much nuclear fragmentation. Other groups of leukocytes form elongated abscesses.

Fig. 3.—From a photomicrograph taken at B in Figure 2. It shows diffuse purulent infiltration, fragmentation, atrophy and hyperchromatosis of the nuclei of the heart muscle.

No. 3: Conditions are practically similar to those found in No. 2.

No. 4: This shows the thin connective tissue septum of the auricle with many connective tissue cells but no muscle fibers. Below the septum in the auriculoventricular groove, the bundle of His can be distinctly seen, together with its branches for the right and left ventricles. The central bundle itself contains many scattered hemorrhages, and the branches for the right and left ventricle soon become involved in the general purulent infiltration, described above. This purulent infiltration can also be seen scattered in certain areas throughout the entire septum, and these areas show intense granular degeneration of the muscle fibers. The purulent infiltration is much more intense just beneath the endocardium of both ventricles, and this infiltration often forms a network between the muscle bundles of degenerated necrotic muscle fibers. The branching of the bundle is well seen in Figure 2.

No. 5: In this section the central bundle has apparently disappeared but the left branch is still visible, and at some distance from the bifurcation, it shows moderate purulent infiltration. There is also marked purulent infiltration of the entire septum in the lower half of the section, especially towards the endocardium of the right ventricle.

No. 6: This section is made from a series of blocks which are perpendicular to the apex and which follow the general course of the two bundles of His, as they course downward in the ventricular septum towards the apex. It is impossible to locate the cross-section of any particular bundle of muscle fibers which would correspond to either of the branches of the bundle of His, and there is no marked purulent infiltration of the muscle in this section. The thickened endocardium shows a slight infiltration with polynuclear leukocytes

and lymphocytes, and there are a few similar groups of cells scattered through the section. There are areas of hemorrhages scattered through the muscular structure, and the blood-vessels are crowded with leukocytes and lymphocytes.

No. 7: This section shows areas of intense hemorrhage together with coagulative necrosis of the muscle fibers, and there is an increase of connective tissue elements between the muscle bundles, indicating a beginning chronic interstitial myocarditis, and some of these areas of coagulative necrosis show marked nuclear fragmentation.

No. 8: In this section through a plane which is nearer the apex, there are, again, areas of marked purulent infiltration with necrosis of the muscle fibers. There is also some chronic interstitial myocarditis and scattered hemorrhages.

No. 9: This ends the series made from blocks approaching the area of the apex, and the conditions are similar to those described in No. 8. A section through several large papillary muscles fails to show any purulent infiltration, but the intense congestion of the capillaries in certain areas of the heart muscle is marked.

No. 10: This section is taken from the first of a series of blocks which pursue a gentle curve around the limits of the auriculoventricular septum ending at the apex. The heart muscle shows extensive necrosis, numerous hemorrhages and congestion of the capillaries, and there is slight, scattered purulent infiltration. The numerous papillary muscles do not show any abnormal changes. A branch of the coronary shows a greatly thickened intima containing numerous connective tissue cells.

No. 11: This tissue shows extensive areas of necrosis and hemorrhages, and these areas are infiltrated by small mononuclear lymphocytes, singly or in groups, and the blood-vessels also contain increased number of lymphocytes.

No. 12: This section is principally marked by extensive areas of hemorrhage and some chronic interstitial myocarditis.

Summary.—It will be seen by reference to Figure 1, that the sections are taken from blocks beginning at the fossa ovalis

Fig. 4.—Area of necrosis with intense nuclear fragmentation and purulent infiltration at A. At B the general purulent infiltration is seen, and at C this purulent infiltration pursues a linear course between the individual muscle fibers.

in the auricular septum, and describing a semicircle passing outward along the horizontal course of the bundle of His, then downward through the ventricular septum, and finally describing a gentle curve, the semicircle ending at the very tip of the apex.

There were no pathologic changes found in that portion of the auricle from which the bundle of His takes its origin. But after the bundle has entered the auriculoventricular groove, it is beset by numerous hemorrhages, and its two branches show moderate purulent infiltration. The rest of the muscular structure of the septum shows marked purulent infiltration in the linear areas beneath the endocardium of

both of the ventricles and in scattered masses throughout the tissue. There is also marked arterio-sclerosis.

Sections From Other Portions of the Heart.—In addition to those described above, sections were made from various other portions of the heart in order to study the extent of the purulent infiltration and the condition of the blood-vessels.

Those of the first set were made from the left auricular appendix, the septum between the auricles, the wall of the right auricle and the muscui pectinati of the right ventricle. The left auricle shows no abnormal changes, but the wall of the right auricle with its muscui pectinati shows a few polynuclear leukocytes in single rows, or small groups, and the nuclei of many of the muscle fibers are shrunken and irregular in size and shape.

Another set of sections was made from the wall of the left ventricle at the left apex, from four separate areas in this wall opposite the septum, and running from the base to the apex, through the papillary muscles, and from the interventricular septum. The first section near the apex shows an adherent antemortem clot attached to the endocardium by means of fibrin. There are many endothelial cells and fibroblasts entering this fibrin in an attempt at organization, and the endocardium is thickened and infiltrated by leukocytes, red blood-corpuscles and fibroblasts. The clot contains masses of fibrin and polynuclear leukocytes and fibroblasts. The muscle fibers next to the endocardium contain numerous large vacuoles, only a mere shell remaining, and the nuclei are frequently shrunken. There is no diffuse purulent infiltration. The five sections from different portions of the left ventricle opposite the septum do not show any marked changes, but the muscle fibers of the papillary muscles near the endocardium show vacuolization. The septum at the apex shows no marked changes, except fatty infiltration near the pericardial surface.

The right coronary artery 6 mm. from the mouth of the aorta shows an interesting condition. The intima is greatly thickened, measuring from 2 to 10 times the thickness of the media adjacent to it, which shows marked atrophy. It contains a moderate number of fibroblasts and two large irregular areas of calcareous deposits. The lumen is completely occluded by a thrombus consisting mainly of red blood-corpuscles and fibrin, but containing groups of organizing fibroblasts and a few polynuclear leukocytes. This thrombus is adherent to the intima from which the endothelium has become detached. A smaller branch of this coronary artery also shows the same thickened intima, and the lumen is reduced to a small irregular channel. The adventitia contains numerous fibroblasts filled with small brown granules of blood pigment, and the muscle fibers of the media show great atrophy. The intima contains scattered polynuclear leukocytes, granular masses of lime salts, and fibroblasts. The same artery nearer the aorta also contains an adherent thrombus of the intima, and shows great thickening of the intima and, just where this is attached to the thrombus, it is highly infiltrated by leukocytes.

SUMMARY

The clinical history of this case indicates that the patient had been suffering from syncopal attacks for a period of seven months. It is difficult to account for these earlier attacks unless we can believe that there were recurrent purulent infiltrations of the bundle of His with damage to the muscle fibers. We found no other lesions of the bundle of His and can only report the patient's condition for about a week prior to his death, together with the discovery of an acute primary purulent infiltration involving the bundle of His.

We desire to thank Dr. H. W. Stoner for the photograph and photomicrographs, and Dr. J. J. O'Malley for assistance rendered.

Bromids in Confirmed Epilepsy.—W. A. Turner, in the *Lancet*, states that in cases of confirmed epilepsy with mental deterioration the bromids are of relatively little value.

A STUDY OF A CASE OF HEART-BLOCK

WITH ALTERNATION OF THE SYSTOLIC AND DIASTOLIC JUGULAR WAVES*

ISAAC IVAN LEMANN, M.D.

Lecturer and Instructor in Medicine, Tulane University
NEW ORLEANS

So much has been written in the past few years about heart-block that the report of a single case can no longer be considered worth while. My reason for reporting the present case is that it presents a feature which, so far as I can learn, has not yet been described. It is apparent from the wide diversity of symptoms and of tracings in the cases constantly being reported that not all cases of heart-block are alike and there is certainly much still to be learned about the clinical picture the disease presents. Each case recording some new point adds to the sum of our knowledge.

Briefly stated, the phenomenon essential to the diagnosis of heart-block is the dissociation of the rates of pulsation of the auricles and ventricles. This is generally attributed to an affection of the bundle of His along which travels the stimulus from auricle to ventricle. The block may be complete, in which case the auricular and ventricular rates are entirely different; or it may be partial, as in my case, when some of the auricular stimuli pass through to the ventricles. The

Fig. 1.—Showing the variation in the pulse; record taken every four hours.

peculiar feature which my patient presented in addition was an alteration of the systolic wave, (*v*), and the diastolic wave, (*h*), appearing in the jugular pulsations.

REPORT OF CASE

History.—The patient, a white male, aged 75, was admitted to the Touro Infirmary, New Orleans, May 17, 1909, complaining of headaches, dizziness, constipation, belching, and involuntary contractions of the abdominal muscles just before going to sleep. His complaints were of four years' standing. His family history was entirely without interest for the present inquiry. He had always been perfectly well and did not remember any other than the most trifling illness. He had had gonorrhea thirty years ago. He chewed and smoked tobacco moderately and seldom drank alcohol.

Examination.—The physical examination showed a well-developed and well-nourished and well-preserved man. The heart was practically normal in size, the apex being just inside the left nipple and the right border at the right border of the sternum. No murmurs were to be heard. There was a moderate peripheral arteriosclerosis. The urine showed no abnormalities. The pulse showed a considerable range in frequency, beating sometimes at the rate of 30 to 35 and at other times as rapidly as 70 to 75. The heart-rate, counted at the apex, corresponded always with the radial pulse. The variation in the pulse is shown in the accompanying chart (Fig. 1), on which is recorded the rate taken every four hours. On June 12, 1909, he had "a spell of dizziness and almost lost con-

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

sciousness for a second." He was taken to his room and there lay down. Shortly afterward his pulse was found to be 36 and weak. Heart-sounds could not be heard. After two or three minutes the pulse jumped to 72 and became stronger. A few weeks after his admission to the hospital he was transferred to the Julius Weis Old Folks' Home, which is a department of the Touro Infirmary, and has remained under observation during the year which has elapsed. He has continued to complain of frequent dizziness but there have been no more syncope attacks.

I was fortunate enough on several occasions to get tracings at the moment of the change in his pulse-rate. Such a tracing is given in Figure 2. This tracing was made October 17, 1909. At the beginning of the tracing the auricular rate was 66 while the ventricular was 33. Every other stimulus from the auricle, therefore, was blocked. The *a-c* interval (the time between the auricle beat and the ventricle beat) was $1\frac{1}{2}$ (expressed in fifths of a second). The normal interval is about one-fifth of a second. At the point marked *x* the block suddenly ceased and all the auricular stimuli passed through to the ventricle. The rates of the auricles and of the ventricles were now both the same, 60. The *a-c* interval continued to be one and a half fifths.

Fig. 2.—Pulse-tracing taken at the moment of change of pulse rate. At the beginning of the tracing the auricular rate was 66, while the ventricular was 33, afterward 60, showing block of every other stimulus from the auricle. No alternation of any waves; $a-c=1\frac{1}{2}$; continues the same after disappearance of block.

Fig. 3.—Tracing showing similar block of every other auricular stimulus. Auricular rate 60; ventricular 31.5; $a-c$ interval= $1\frac{1}{2}$; no alternation of waves.

Figure 3 shows a tracing taken Feb. 20, 1910. Here there is a similar block of every other auricular stimulus. The ventricular rate was 31 and the auricular rate 60. The *a-c* interval was somewhat longer than on the previous occasion, being one and two-thirds as compared to one and a half. Neither of these tracings presents the unusual alternation of the systolic and diastolic waves. This is seen apparently only in tracings where there is no heart-block. A good illustration is given in Figure 4. Here it is very easy to see in the jugular (the upper tracing) that the waves *v* and *h* are alternately high and low. Thus in cycles 6 and 8 they are high and in 7 and 9 they are low. The alternation is clearer in Figure 5, where the enlargement is greater. The wave *h* is not lettered here but it is the wave following immediately after the *v* and it will be observed that its alternation corresponds to that of the *v* wave. In both of these tracings there is no block, although the slowness of the radial pulse would have led one to suspect its occurrence. The rate of both auricles and ventricles was 46. The delay of the auricular stimuli is evidenced by the increased *a-c* interval—two-fifths of a second.

In order to attempt an explanation of this alternation it is necessary to stop here to inquire into the manner in which these waves are produced. The wave *v* is explained by Mackenzie¹ in this way: The blood (during ventricular systole) "comes mainly from the periphery into the auricles through the veins. When the auricle becomes filled the surplus distends the superior vena cava and jugular, and hence appears in the tracing as a wave." If we assume this as the correct explanation of the occurrence of the wave, then we must, in order to account for the alternation, assume that in some instances there is a greater surplus distending the vena cava and jugular than in other instances, or at any rate the surplus is sent back or held back with varying force. Since there is no reason to think that the amount of blood flowing from the periphery through the veins to the auricles varies so considerably and so regularly in volume from second to second, we are forced to consider that the cause of the alternation must lie in some condition of the auricular wall. It seems probable that a varying tonicity would permit the auricle to be distended to a varying degree. At times, therefore, the auricle would contain a larger amount of blood than

at others, and in consequence there would be a smaller surplus left to distend the vena cava and the jugular. This would make a smaller wave. When the tone of the auricle was greater a smaller amount of blood would be accommodated, a larger surplus would overflow into the vena cava and jugular and a large wave would be caused. The common occurrence of a pulsus alternans in the peripheral circulation presents an analogy which may be used as an argument in favor of the explanation I offer. If there may exist an alternation of the contractility of the ventricle, is it not reasonable to suppose that there may be an alternation of the tonicity of the auricle?

We may now turn our attention to the *h* wave and shall find, as I think, that the cause of its alternation lies in the same variability of the auricular tone. This *h* wave was described by Gibson² and Hirschfelder³ (independently) to the inrush of the blood from the auricles into the ventricles after the opening of the aortic over-

1. Mackenzie: Diseases of the Heart.
2. Gibson: Lancet, London, Nov. 16, 1907.
3. Hirschfelder: Am. Jour. Med. Sc., September, 1906.

tricular valves, causing the leaflets to be floated up, and bringing about a transient closure of the valves. This explanation is generally accepted. If this is correct, then it is apparent that the condition of the auricular wall will be the chief factor in determining the size of the wave, which will record the influence of this closing of the valves as a wave in the jugular tracing.

The tracing shown in Figure 6 was obtained at the same sitting as that in Figure 4. The plateaus succeeding the *v* waves and preceding the carotid, *c* waves were thought when the tracing was first studied to be due to the auricular contractions. In other words, they were considered to be *a* waves. There was, therefore, apparently an alternating condition of the auricular contractility. This was, however, a faulty interpretation as we shall see in a moment. Such an alternans action of the auricles has been described by Griffith.⁴ It was accompanied by an alternating ventricular contraction.

ure 6, and in comparing it with the other tracing made at the same time, it became evident that the plateaus already mentioned were due not to the auricular contraction *a*, but to *h* plus *a*. The initial rise of the plateau is due to the *h* wave and its level is maintained by the oncoming of the *a* wave which is not visible as an additional rise.

On two occasions I tried to ascertain the effect of atropin on the block. On both occasions I gave 1/60 of a grain hypodermatically and in both instances there was absolutely no result from its administration. Although the radial pulse was slow, (46), and I had expected to find a block present, this was not the case either time. Hence, I am unable to say what effect atropin would have on the block.

I desire to express my obligation to Prof. George Dock, who first pointed out the alternation of the waves.
602 Perrin Building.

Fig. 4.—Tracing made when there was no block, showing the alternation from high to low. Diastolic wave *h*; alternation of *v*; alternation of *h*; *a*—*c*; ventricular rate 46. No block.

Fig. 5.—In this figure the alternation is clearer, the enlargement being greater. Ventricular rate 46; alternation of *v*; alternation of *h*.

Fig. 6.—Tracing obtained at same sitting as Figure 5, showing apparent alternation of *a* waves. The initial rise following the *v* wave is due to the *h* wave and its level is maintained by the oncoming of the *a* wave, which latter is not visible as an additional rise, hence *a*—*c* cannot be measured. Ventricular rate 46.

Griffith explains the alternately large and small auricular waves as follows:

The primary condition is the alternans action of the ventricles. When the systoles are strong they last long enough to prevent the quickly following auricular contraction from driving the blood freely or at all into the ventricles and so a large wave is seen in the jugulars. When the ventricular systoles are weak they do not last so long, and the auricle can drive its blood in larger amount into the ventricle and consequently the jugular wave will be smaller. It is of course only when the *a*—*c* interval is unduly long, as it was in this case, that alternately large and small auricular waves could be determined in this way by an alternans ventricular action.

There was, however, no condition of this sort present in my case. On a closer analysis of the tracing in Fig.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LEMANN AND BECK AND STOKES

DR. HAVEN EMERSON, New York: I have been much interested in result of experimental procedures or distention of the auricles with saline solutions. If one places a dog under ether anesthesia, and floods the auricles quickly with saline solution, the animal will develop auricular paralysis. But if one makes a slow infusion of the saline solution, there will result a condition of auricular vibration (fibrillation). It has been found that by replacing the blood of any tissue by any of the usual artificial circulation ordinary fluids we alter the tone of that tissue, especially the muscular tissue; therefore it is entirely conceivable that by flooding the auricles with saline solution there results an alteration of the *a* wave such as shown by the study just reported. The analysis of heart-block has been explained as being the result of an alteration of the tonicity of the auricular wall. So far as is known, the tonicity of the blood vessels alters but slowly. It must be

remembered that the heart muscle has been shown to correspond in every way with the skeletal muscles as regards the output of work and conditions under which work may be done to the best advantage as regards time or load. The heart muscle, however, does not appear to alter in tone so rapidly as do the skeletal muscles. We should consider the possibility that the tone of the muscle of the heart may alternate nearly as does the tone of the skeletal muscles. Until we can prove consistently that certain procedures alter the tone of the heart muscle we must be conservative in accepting such a change of tone as an explanation of or accompaniment of heart-blocks as instanced in the papers read.

DR. ALBERT E. TAUSSIG, St. Louis: I have under observation a case of congenital stenosis of the pulmonic orifice with a patent ductus arteriosus which shows a phenomenon similar to that described by Dr. Lehmann. The patient is a young man, aged 19, a shoemaker. He is able to earn a good living at his work in spite of his cardiac defect. The heart is enlarged and he has the typical murmur and other phenomena characteristic of stenosis of the pulmonic orifice. The *a* wave in the jugular bulb is exaggerated and shows well-marked alternation in height, especially when he is under the influence of digitalis. Tracings taken some weeks ago show that the radial pulse is about normal, while the jugular pulse shows a high *a* wave which alternates in height. This alternation occasionally fails. Another interesting feature of these curves is that at the same time of the alternation of the *a* wave there is an alternation of the *a-c* interval. The higher the *a* wave the longer the *a-c* interval. This is the reverse of what one might expect *a priori*.

INSTRUCTION OF THE PUBLIC IN ANTI-TUBERCULOSIS MEASURES BY A TRAVELING CAR EXHIBIT

GEORGE HOMAN, M.D.

Chairman Executive Committee, Missouri Association for the Relief and Control of Tuberculosis

ST. LOUIS

When the Missouri Association for the Relief and Control of Tuberculosis was formed in 1907 a main purpose of the organization was declared to be the enlightenment of the public on the disease in question by means of lectures, addresses, demonstrations, and exhibits, these activities being a necessary preliminary to a right understanding of the subject thus presented, and

Fig. 1.—Exterior view of antituberculosis exhibit car.

to afford an intelligent basis on which local organization could be brought about.

To the extent that its limited means allowed a consistent effort was therefore made by the association to enlist the interest and aid of local communities through their medical, social and business organizations, and with some success, the medical societies naturally being the leaders and chief supporters of such movements and auxiliary branches were formed in a number of cities and counties of the state. It was found, however, that these bodies tended in time to become listless, and in

casting about for other means of awakening interest in the subject of tuberculosis and its prevention, the idea was conceived that a well-chosen exhibit installed in a railway coach and sent over the railroad lines in charge of a qualified staff would very likely prove to be the most effective form in which such an object lesson could be presented to the public at large.

With this end in view the association early in 1908 made overtures to the State Board of Health suggesting cooperation and joint effort to accomplish this undertaking, but as an outcome difficulties appeared and the negotiations were brought to a close.

Fig. 2.—Interior view of antituberculosis car.

The project, however, was not lost sight of and endeavors were made to secure funds for this purpose, which hope was realized last June when the announcement was made in the Section on Preventive Medicine and Public Hygiene at the annual meeting of the American Medical Association in St. Louis that a check was in hand ample in amount to cover for a limited time the expenses involved in the equipment and operation of the contemplated railroad car service.*

The managers of railway systems operating lines in Missouri were at once approached with representations touching the plans of the association, with the result of securing a prompt response from the St. Louis and San Francisco System, a first-class day coach being tendered with a promise that it would be turned out of the shops in complete order to receive the exhibit as planned, with special devices for hanging and lighting, no charge to be made for the car or for hauling it, while free transportation for five persons would be supplied, if desired, this gratuitous service including even gas, ice, etc.

The St. Louis Municipal Commission on Tuberculosis with generous public spirit offered the free use of their valuable framed exhibit, which it was found could be used to superior advantage in fitting out the car, and acknowledgment of this graceful courtesy was made accordingly.

* The donor of this fund was Mr. Adolphus Busch, a distinguished citizen of St. Louis, who is widely known as a generous giver to many worthy causes. The work of preparing the car for the road in all its details was placed in the hands of a subcommittee composed of Mr. J. H. Lynch, treasurer of the association, Dr. James Stewart and Mr. Robert J. Newton, secretary of the Municipal Commission on Tuberculosis. Miss W. Doyle, assistant secretary to the association, served as advance agent to the car.

The final details respecting the supervision, equipment, routing, etc., of the car were completed toward the end of July, and August 1 was fixed on as the date for starting, a time schedule having been prepared by the officials of the road which covered twenty-four days and provided for stops and demonstrations at thirty-eight towns and cities located in twenty-eight different counties.

It was decided that the offer by Dr. James Stewart, medical supervisor to the St. Louis Board of Education, of his services free as lecturer in full charge of the car be gratefully accepted, and he was provided with a paid helper to look after the property, work the stereopticon and give aid in other ways as required, sleeping quarters being provided for him in the car. It was arranged further that the assistant secretary should travel from five to seven days in advance of the car and make all necessary arrangements for the meetings with the local people at the designated stopping places, getting at once in touch with public officials, physicians, newspaper men, clergy, business men, club women, etc., notices being regularly mailed ahead stating what was desired by her.

The car left St. Louis as per schedule going southward through territory bordering on the Mississippi River to the extreme southeastern part of the state, thence westward along the southern slope of the Ozarks to Springfield and the thickly peopled lead and zinc mining districts of southwest Missouri; then northward along the western border to Kansas City, where two days were spent, the exhibit being removed from the car to the business center of the city. Returning to Springfield by another route, St. Louis was reached by the trunk line of the Frisco system, the schedule having been extended four days in response to a popular demand for more time at different stopping places, the tour closing August 28.

On its second tour the car left St. Louis September 7, via the Missouri, Kansas and Texas system, the plan being to traverse the entire central part of the state from Hannibal on the Mississippi River to St. Joseph on the western border, covering both sides of the Missouri River and visiting some of the oldest and most thickly populated parts of the state. The return route was to be by way of the Rock Island railroad, this system equaling the others in the courtesies and services freely extended. The success of this further undertaking seems undoubted as increasing attendance at lectures, with financial support, and growing public interest have uniformly marked its course.

In fitting up the car the space was utilized to the utmost by the device of a partition lengthwise in the center formed of framed pictures hung back to back, as imperfectly shown in the accompanying illustration. The end and side walls were also fully utilized, and on shelves and in lockers an ample supply of literature, buttons, post cards, sanitary folding cups, etc., was to be found.

The association was fortunate in securing the services of Dr. Stewart for this work, who, as a former member of the Missouri General Assembly, was successful in securing legislation providing for the state sanatorium now located at Mount Vernon. A part of the purpose of this tour was that every proper effort should be made to meet the candidates for the legislature in each county and explain to them the objects in view, and by thus

interesting them and their people, to secure support for such recommendations on public health lines as may be submitted to the legislative body by the Governor at the session which opens next January, and in this direction much encouragement is reported as a result of the trip. Indeed, it may be claimed with justice, that for a venture which, so far as known, stands unique in its character as a pioneer effort, the undertaking was a conspicuous success, large and interested gatherings being the rule, tuberculous people in rural parts sometimes traveling as many as thirty or forty miles to reach the car in the hope of learning something of benefit to themselves.

It is evident that the higher officials of some of the leading railway lines are beginning to realize the value of such public teaching in disease repression, and this fact was plainly shown in the cordial zeal and skill with which this undertaking was promoted down to the minutest details by Mr. A. Hilton, general passenger agent of the Frisco road, supplemented at certain points by the Saint Louis Southwestern, and the Missouri Pacific railroads, reaching in all a population, not including Kansas City, of nearly a quarter million of people, 1,248 miles being traversed in the tour of the car.

The Missouri, Kansas & Texas Railway management have tendered to this association every facility at their disposal for the operation of the exhibit car over their lines, by means of which a very considerable additional population can be reached, and it is hoped that all the other systems will see the advantage of like action in the warfare against consumption.

A keen interest in public health affairs could have been the only inducement which led the governor of Missouri, Hon. Herbert S. Hadley, to consent to accept the presidency of this association, and this interest was shown to a still greater degree by the official naming of a commission of twenty or more citizens of this state whose duty it will be to make thorough inquiry respecting tuberculosis in Missouri, and frame a report on which he may base recommendations to the legislature for remedial action next year.

While it was found that a considerable financial outlay is involved in the operation of such a traveling exhibit, even when much necessary service is rendered free of charge, still it is firmly believed that the returns to the public in the form of a better knowledge of disease prevention fully repays such expenditures, and it is the hope of the association that additional financial means will be forthcoming to enable this form of instruction to be pushed into every part of the state where the railroads penetrate. Thus far practically the whole burden of this work has been borne in St. Louis, and the available funds of the association have been exhausted in the enterprise herein sketched.

As before indicated, much of the best help and cooperation at the different points was given by the organized medical profession, officials of local societies, councilors, and the president of the state association, Dr. H. E. Pearse, all lending a hand with full sympathy and good will to forward the cause. A number of leading physicians along the route even volunteered their services for work with the car if future tours were found possible. Another factor making for the success achieved was the public press, many of the papers giving columns of space to descriptions, with pictures, etc., showing the work and purposes of the car.

ALOPECIA AND SEBORRHEA *

CHARLES J. WHITE, M.D.

Instructor in Dermatology in Harvard University
BOSTON

Dandruff and loss of hair are two of the minor afflictions of civilized life which are usually sources of constant chagrin to the unfortunate men and women who fall victims to their presence. One or both of these conditions, which even we ourselves experience sooner or later, are brought to our attention as dermatologists so frequently that it seems fitting from time to time to present them as themes for discussion when we meet in the hope that some member here may contribute some small bit of knowledge to a subject which needs so much help from an etiologic and therapeutic standpoint. It is, therefore, because we practitioners are usually so helpless when confronted by a well-established case of alopecia or of seborrhea that I have ventured to summarize my knowledge of these conditions gleaned from the study of 794 examples observed in my personal private practice.

In the following pages I shall deal principally with seborrhea capitis and with alopecia simplex and alopecia furfuracea, but I shall speak superficially on alopecia areata, and alopecia from ringworm, syphilis and overexposure to x-rays.

ALOPECIA

Statistically, I record 679 cases of loss of hair divided clinically as follows:

	Cases	Males	Females
Alopecia simplex ¹	115	37	78
Alopecia furfuracea	443	206	237
Alopecia areata	86	46	40
Alopecia from ringworm.....	16	9	7
Alopecia from syphilis.....	17	11	6
Alopecia from x-rays.....	2	1	1
	679	310	369

From these figures it will be seen that women are more often affected by loss of hair than men, in the relative proportion of 54 and 46, unless it be that women feel this loss more keenly and therefore consult physicians more freely on this account. It is interesting, however, to note the figures of Elliot,² who in his paper of 1892 records about identical percentages, viz. 55 per cent. women and 44 per cent. men. Jackson,³ on the other hand, in 1893 found the proportions reversed and recorded alopecia in 52 per cent. males and 48 per cent. females.

Possible Etiologic Factors in Alopecia Simplex and Alopecia Furfuracea

From a study of my records it will be noted that heredity, dandruff, systemic depression, fever, operations and maltreatment of the scalp have been connected in the patients' minds with the production of the fall of the hair. Under the heading of systemic depression figure overwork, worry, nervous exhaustion and prostration, recent immigration or foreign travel, pregnancies, and chronic diseases or invalidism. The term "maltreatment of the scalp" is based on my own per-

sonal theories as to what is right and what is wrong in the hygiene of the scalp and includes the rough usage of brushes, combs and massage in the presence of dandruff; shampoos less often than once a month or more frequently than once a week; the use of any drugs in any form on the healthy hair or scalp; the continued application of too drying alkaline soaps; the frequent or constant exposure of the uncovered head to the summer sun; the daily sousing of the head in shower-baths or in salt water; and the modern over-treatment of the normal scalp by barbers and hairdressers.

Statistically we find these factors summed up as follows:

	Cases
Heredity: Father's side of the house.....	108
Mother's side of the house.....	51
Not recorded	12
	171
Alopecia present in brothers or sisters.....	72

From these figures it is seen that a hereditary taint exists in 30 per cent. of these individuals. Dandruff was present in 443 patients, a percentage of 79+. Systemic depression was recorded in 120 cases, a percentage of 21+. Fever was noted in 63 individuals, a percentage of 11+. Operations were blamed in 12 persons, a percentage of 2+. Maltreatment was evident in 277 patients, a percentage of nearly 50; and, finally, more than one of the above possible etiologic factors was found in 386 cases, a percentage of approximately 70.

It may be interesting to pause a moment and compare these figures with those of Dr. G. T. Elliot⁴ and of Dr. G. T. Jackson³ who based their figures on 344 and 300 cases respectively.

	Heredity	Systemic Causes	Seborrhea
Elliot	1.16*	5.52	91.68
Jackson	38.32		72.66
C. J. White.....	30.64	21.50	79.39

* This percentage relates to alopecia simplex only.

The figures which follow in the rest of this paper are not wholly satisfactory and are comparatively small, as the symptoms had existed so long in many cases that patients were unable to remember the exact date of their beginnings.

Ages When Alopecia Simplex First Appeared

Among those who could be exact there were 25 males and 43 females out of a possible 37 and 78 respectively.

Males: 7 cases began between 16 and 20.
8 cases began between 21 and 25.
6 cases began between 26 and 30.
1 case began at 35.
1 case began at 39.
2 cases began at 46.

It will be seen that this clinically uncomplicated type of loss of hair begins at or before the age of 30 in 84 per cent. of the male cases.

Females: 7 cases began at or before the age of 15.
3 cases began between 16 and 20.
5 cases began between 21 and 25.
4 cases began between 26 and 30.
7 cases began between 31 and 35.
2 cases began between 36 and 40.
6 cases began between 41 and 45.
6 cases began between 46 and 50.
2 cases began between 51 and 55.
1 case began at or before the age of 56.

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. By this term is meant the simple loss of hair without other objective symptoms.

2. Elliot, G. T.: Sixteenth Annual Meeting of Am. Derm. Assn.; see report, p. 81.

3. Jackson, G. T.: Loss of Hair, a Clinical Study Formed in 300 Private Cases, Tr. Am. Dermat. Assn., 1900, p. 50.

4. Elliot, G. T.: Alopecia and Its Most Frequent Cause, Dermatitis Seborrheica, Tr. Am. Dermat. Assn., 1895, p. 95.

Of the seven early cases five followed acute febrile disturbances. Between the ages of 15 and 30, however, we find that 33 per cent. of these women developed their simple alopecia, contrasted with a respective percentage of 84 in men, whereas between the ages of 31 and 50 we note a percentage of 58, figures which force us to the conclusion that alopecia simplex develops much later in women than in men.

Ages When Dandruff and Alopecia Appeared in Alopecia Furfuracea

DANDRUFF

Males, 91 cases.

3 cases	began between 9 and 10
8 cases	began between 11 and 15
31 cases	began between 16 and 20
25 cases	began between 21 and 25
14 cases	began between 26 and 30
8 cases	began between 31 and 35
1 case	began at 37 and 1 at 43

Females, 75 cases.

3 cases	began between 7 and 10
12 cases	began between 11 and 15
10 cases	began between 16 and 20
13 cases	began between 21 and 25
11 cases	began between 26 and 30
12 cases	began between 31 and 35
7 cases	began between 36 and 40
3 cases	began between 42 and 45
4 cases	began between 46 and 56

Contrasting these two columns of statistics we are struck by two facts, viz., that men are more prone to remember the exact date when their dandruff began than is the case with women and that in these men and women seborrhea capitis appeared at an earlier period in the former sex than in the latter. Thus between the years 16 and 25 we find 61 per cent. of males developing their dandruff while in females at a similar epoch we find but 32 per cent.

ALOPECIA

Males, 127 cases.

6 cases	began between 10 and 15
30 cases	began between 16 and 20
55 cases	began between 21 and 25
14 cases	began between 26 and 30
14 cases	began between 31 and 35
2 cases	began between 36 and 40
3 cases	began between 41 and 45
2 cases	began between 46 and 50
1 case	began at 60

Females, 129 cases.

7 cases	began between 12 and 15
24 cases	began between 16 and 20
21 cases	began between 21 and 25
25 cases	began between 26 and 30
25 cases	began between 31 and 35
16 cases	began between 36 and 40
5 cases	began between 41 and 45
1 each	at 46, 51, 54, 61, 63 and 68

In these columns it is seen that men and women are apparently equally impressed by the exact age at which their hair begins to fall but that between the ages of 16 and 25 alopecia develops in 67 per cent. of the men affected against 34 per cent. in the women.

Thus from these foregoing contrasting figures we learn that men are attacked much earlier than the opposite sex by alopecia furfuracea whereas women as a whole become the victims of alopecia, either simple or furfuraceous, more often than men, in fact, in the proportion of 56 to 43.

Varieties, Distribution, and Subjective Symptoms of Dandruff and Loss of Hair in Alopecia Furfuracea

DANDRUFF	Cases.	ALOPECIA	Cases.
Slight in	127	Slight in	67
Abundant in	199	Marked in	130
Localized in	83	General in	30
Yellow-brown in	56	Principally on forehead	
Oily in	78	in	119
Dry in	53	Principally on top of	
Granular in	23	head in	79
Adherent in	38	Principally on sides in..	13
Loose and large in	39	Principally at tonsure in	38
Accompanied by pruritus		Hair dry in	37
in	97	Hair greasy in	15
Accompanied by burning		Hair split in	49
in	3	Hair short in	34
Accompanied by hyperid-		Hair coarse in	8
rosis in	30	Hair fine in	21

These figures require no elucidation. It is evident from their study that in alopecia furfuracea we may expect to encounter more often well-marked examples of seborrhea and of loss of hair than the reverse; that dandruff is usually general in distribution, while alopecia is generally localized; that dandruff is frequently accompanied by subjective symptoms and is often associated very strikingly with many changes in the texture of the hair as well as in its loss.

The Treatment of Alopecia Furfuracea

I fear that we must all agree that our therapeutic results in this disease are very disheartening. I tell all my patients who have noted this condition for more than a few months, and especially those whose forebears have been similarly affected, that a permanent cure is hardly to be hoped for, but that by long and continued perseverance on their part they may keep their scalps clean and delay the inevitable baldness for years.

The medical aphorism which tells us that therapeutic non-success may be judged by the multiplicity of the drugs recommended in a given disease is well emphasized in the present instance.

My armamentarium has included the following medications:

Washes, containing 70 per cent. alcohol, quinin, cantharides, capsicum, pilocarpin, chloral hydrate, tartaric and salicylic acids, phenol, formaldehyd, trikresol, anthrasol, and croton and turpentine oils.

Ointments, containing sulphur, salicylic acid, zinc oxid, resorcin, oil of cade, ichthyol, succus limonis, yellow oxid and ammoniated chlorid of mercury, orthoform and bichlorate of soda.

Soaps, containing betanaphthol and glycerin.

Internal medication, including iron, nux vomica, magnesium sulphate, dilute sulphuric acid, betanaphthol, malt, cod-liver oil, phenyl salicylate, ichthyol, salicin, thyroid extract and phosphate of soda.

Massage.

Despite this long list I practically confine myself to four prescriptions which I append:

1. R. gm. or c.c.
Acid. salicyl
Sulph. precip. aa 2 } or 5ss
Petrolatum 32 } 5i
M. S.—Ointment. Apply at night. Shampoo with a simple soap the following day.

2. R. gm. or c.c.
Pilocarpin nitrat. 106 } gr. i
Quinin sulph. 6 } or gr. x
Tr. canthar.
Tr. capsic. aa 10 } 3iii
Alcohol, 70 per cent. ad. 250 } fl. 3viii
M. S.—Wash for scalp. Apply in the morning.

3. R.	gm. or c.c.	
Acid tannic	2 1/2	gr. xxxv
Chloral hydrate	1 1/2	gr. xxvii
Acid tartaric	2	gr. xxx
Ol. ricini	1	or m. xv
Alcohol, 70 per cent.	200	fl. 5vi
M. S.—Wash for scalp. Apply in the morning.		
4. R.	gm. or c.c.	
Hydrarg. chlorid. corrosiv.	24	gr. iv
Euresol	8	or 5ii
Sp. formicarum	30	5i
Ol. ricini	4-12	5i-iii
Alcohol, 70 per cent. ad.	250	5viii
M. S.—Wash for scalp (poison). Apply two teaspoonfuls in the morning.		

The last of these four I hold easily first in its successful results. I associate its formula with Dr. G. T. Elliot, and it has proved a veritable godsend to me in treating many of these almost impossible cases. The essential feature in its composition is, I believe, euresol—the mono-acetate of resorcin. The smell of this salt is a very unfortunate factor, however, but one which the manufacturers have not been able to eradicate without markedly diminishing the value of the drug. The chloralhydrate wash I place second in efficacy.

Perhaps the most striking feature of these four prescriptions seems to be the absence of pure resorcin from their composition. I am free to confess that I never have been able to reduce its strength sufficiently to render it anything but an irritant to the scalp.

Results of Treatment Summarized by Age

MALES, 200 CASES			
Very good, 16 cases		Slight, 58 cases	
At 19	2 cases	Between 15 and 20, 10 cases	
Between 20 and 25, 4 cases		Between 21 and 25, 20 cases	
Between 26 and 30, 3 cases		Between 26 and 30, 13 cases	
At 31	1 case	Between 31 and 35, 6 cases	
Between 41 and 45, 3 cases		Between 36 and 40, 2 cases	
Between 46 and 50, 2 cases		Between 41 and 50, 4 cases	
At 58	1 case	Between 53 and 63, 3 cases	
Good, 80 cases		Poor, 37 cases	
At 13 and 14, 2 cases		At 18 and 19, 2 cases	
Between 16 and 20, 10 cases		Between 21 and 25, 14 cases	
Between 21 and 25, 16 cases		Between 26 and 30, 8 cases	
Between 26 and 30, 23 cases		Between 31 and 35, 7 cases	
Between 31 and 35, 13 cases		Between 36 and 40, 4 cases	
Between 36 and 40, 9 cases		Between 42 and 46, 2 cases	
Between 41 and 45, 3 cases		Bad, 9 cases	
At 49, 56, 65 and 75, 1 case		Between 20 and 26, 4 cases	
		At 32	2 cases
		At 38, 42 and 53, 1 case	
FEMALES, 194 CASES			
Very good, 17 cases		Good, 93 cases	
At 13	1 case	Between 11 and 14, 4 cases	
Between 26 and 30, 4 cases		Between 16 and 20, 7 cases	
Between 31 and 35, 5 cases		Between 21 and 25, 19 cases	
At 38	2 cases	Between 26 and 30, 15 cases	
Between 47 and 50, 3 cases		Between 31 and 35, 16 cases	
Between 56 and 60, 2 cases		Between 36 and 40, 12 cases	
Slight, 53 cases		Between 41 and 45, 7 cases	
Between 5 and 9, 2 cases		Between 46 and 50, 4 cases	
Between 13 and 15, 4 cases		Between 51 and 55, 3 cases	
Between 16 and 20, 2 cases		Between 57 and 60, 3 cases	
Between 21 and 25, 11 cases		At 63, 80, 83 each, 1 case	
Between 26 and 30, 11 cases		Poor, 25 cases	
Between 31 and 35, 7 cases		Between 11 and 15, 2 cases	
Between 36 and 40, 4 cases		Between 16 and 20, 2 cases	
Between 41 and 45, 3 cases		Between 21 and 25, 3 cases	
Between 46 and 50, 5 cases		Between 26 and 30, 6 cases	
Between 51 and 55, 2 cases		Between 31 and 35, 4 cases	
At 70	2 cases	Between 36 and 40, 2 cases	
Bad, 6 cases		At 50, 56, 60	2 cases
At 15	1 case		
Between 30 and 37, 2 cases			
Between 43 and 48, 3 cases			

These figures are comparatively small because many patients came but once and hence cannot be included in these lists.

From these figures it is seen that the prognosis in women is better than in men in the proportion of 56 per cent. to 48 per cent. These percentages are based on the "very good" and the "good" results in both sexes; and in addition we see that there were fewer "poor" and "bad" results in women than in the men in the proportion of 16 per cent. to 23 per cent. Therefore, we may encourage our feminine patients decidedly more than we can our masculine.

SEBORRHEA

Included in this study of 794 cases were found 117 individuals who were the subjects of dandruff alone. It is rather a disconcerting fact to find so many examples of seborrhea capitis without resulting loss of hair, especially as this condition had existed for many years in many of these people—disconcerting because in this paper it has been inferred, at least, that dandruff is the most frequent cause of alopecia. Nevertheless, when the data are put into cold figures it will be found that these inferences are perhaps not wholly wrong. In the list there are 115 cases of alopecia simplex or a total number of 232 individuals in whom dandruff has played no part in the production of loss of hair. On the other hand, there is a total of 443 men, women, and children, a ratio of nearly two to one, in whom dandruff and loss of hair were present and in whom, by the figures in the great majority of instances, the seborrhea had preceded the alopecia for varying lengths of time.

To return to our cases of seborrhea simplex. Of the 117 examples 54 were males and 63 females, a ratio of 46 to 54—a distinct feminine preponderance and curiously enough corresponding absolutely exactly to our percentages of alopecia from various causes recorded in the early part of this communication (see above).

Age When Seborrhea Began

Males, 32 cases		Females, 29 cases	
At 1, 11, 14 each, 1 case		At 1, 7 each, 1 case	
Between 16 and 20, 8 cases		Between 10 and 15, 7 cases	
Between 21 and 25, 2 cases		Between 16 and 20, 10 cases	
Between 26 and 30, 10 cases		Between 21 and 25, 3 cases	
Between 36 and 40, 4 cases		Between 26 and 30, 4 cases	
Between 53 and 60, 4 cases		At 41	1 case
At 65	1 case		

These are rather small figures from which to draw conclusions but one is struck by the fact that dandruff comes on in childhood or in early adult life—71 per cent. in men and 96 per cent. in women exhibiting this symptom at or before the age of 30.

Incidence of Seborrheic Symptoms Other Than Dandruff

For some years it has been my custom to regard seborrhea as merely the cutaneous evidence of some internal disorder and to look on acne vulgaris, acne rosacea, eczema seborrheicum and Fordyce's disease of the lips as similar expressions of the same general disturbance. So, from a study of these records, I find that in the 443 cases of alopecia furfuracea there were 57 individuals (a percentage of 12, consisting of 31 males, and 20 females) who exhibited one or more of these allied eruptions; while in the 117 examples of seborrhea simplex there were 29 men and 38 women (a total of 67, or a percentage of 57) with similar efflorescences.

DYSPEPSIA

As to the nature of the fundamental disorder which, some think, lies at the bottom of these seborrheic symptoms we are decidedly at sea. Many of us, however, are wont to accuse digestive disturbances as possible sources of trouble and in this series of cases clinical evidences of dyspepsia have been found in the following percentages: in alopecia simplex 3; in alopecia furfuracea 8; and in seborrhea simplex 17. Surely, these are small crumbs of comfort to the believers in the digestive origin of these disorders.

Regions Affected in Alopecia Areata and in Ringworm

ALOPECIA AREATA, 86 CASES

Scalp, 71 cases		Ringworm, 9 cases	
Occipital,	36 cases = 50 %	Occiput,	5 cases = 55 %
Parietal,	11 cases = 15 %	Top of head,	2 cases = 22 %
Top of head,	8 cases = 11 %	Sides,	1 case = 11 %
Frontal,	5 cases = 7 %	Beard,	1 case = 11 %
General,	11 cases = 15 %	Face, 21 cases	
		Beard,	13 cases = 62 %
		Upper lip,	5 cases = 24 %
		Eyebrows,	3 cases = 14 %

No comment is necessary on these figures; they are very small but they speak for themselves. In scrutinizing my cases of alopecia areata I was struck by the marked incidence of an accompanying dandruff. This statement of course coincides with Sabouraud's dictum that pathologically and bacteriologically seborrhea always precedes or accompanies alopecia areata. Another fact impressed on my mind in the study of these cases is that one attack of alopecia areata very often leads to one or more successive outbreaks.

SUMMARY

This then brings me to the end of these numerous columns of figures and deductions, which in conclusion I may summarize as follows:

1. Alopecia accompanied by dandruff is the commonest type of loss of hair.
2. Women are more prone to alopecia than men, in the proportion of 54 to 46.
3. The possible and principal causal factors of alopecia are heredity in 30 per cent., dandruff in 79 per cent., systemic depression in 20 per cent., fever in 11 per cent., and maltreatment of the scalp in 50 per cent.
4. Alopecia simplex develops before the age of 30 in 84 per cent. of the men, but in only 33 per cent. of the women.
5. Dandruff behaves in a similar manner and before the age of 25 attacks 61 per cent. of its future male victims but only 32 per cent. of its female.
6. The loss of hair in alopecia furfuracea comports itself with these previous two findings, appearing before the age of 25 in 67 per cent. of the men, but only in 34 per cent. of the women.
7. Summarizing paragraphs 2, 4, 5, and 6, we find that men are attacked earlier than women with alopecia and with seborrhea but that eventually women rather than men fall victims to these conditions.
8. When dandruff is present it is apt to be abundant rather than slight, oily rather than dry, and to be accompanied by itching.
9. With alopecia we find well-marked cases rather than mild ones, located in the great majority of the cases in the frontal and temporal regions and accompanied by hair which is apt to be dry, split, short and fine.

10. The drugs most successful in the treatment of dandruff and loss of hair are euresol, bichlorid of mercury, tannic acid and chloral hydrate.

11. The final results of treatment in these affections are almost disheartening, but judged from a temporary point of view, we may expect good or very good response in 48 per cent. of men and in 56 per cent. of women.

12. Seborrhea may exist for years without entailing any appreciable loss of hair; nevertheless, dandruff does seem to be followed or accompanied by alopecia twice as often as not.

13. Seborrhea simplex is a disease of childhood or early adult life, developing before the age of 30 in 71 per cent. of men and 96 per cent. of women.

14. Other seborrheas of the skin such as acne vulgaris, acne rosacea, eczema seborrheicum and Fordyce's disease, may accompany loss of hair and dandruff. Their percentages of concomitance, however, vary, and consist of 12 per cent. in alopecia furfuracea and 57 per cent. in seborrhea simplex.

15. Dyspepsia, on the other hand, exists in surprisingly small percentages in these cases, being present in only 3 per cent. in alopecia simplex, 8 per cent. in alopecia furfuracea, and 17 per cent. in seborrhea simplex.

16. From the preceding two paragraphs we may induce that seborrhea simplex is a truer form of dandruff than that accompanying loss of hair.

17. In alopecia areata and in ringworm of the scalp, the region most affected is the occipital.

18. In alopecia areata dandruff is a frequent accompaniment and we also find that one attack of the disease is apt to be followed by one or more later outbreaks.

259 Marlborough Street.

ABSTRACT OF DISCUSSION

DR. WILLIAM O. ROOF, Dayton: I indorse Dr. White's statement in regard to the value of euresol in treatment of these diseases of the scalp. I have frequently included it in my application in the treatment of these seborrheic conditions, and it has given me better results than some of the older remedies.

I have been consulted during the past year in several cases of alopecia areata, and in all I was particularly struck by the accompanying seborrhea; and while the recognized treatment has always been of a stimulating character, I felt that inasmuch as the etiology of alopecia areata is somewhat in dispute, that perhaps the same treatment as for seborrhea, and of a less stimulating character than that usually employed, might be successful. With that idea in view, I used a simple ointment of sulphur and resorcin, rubbing it into the patches at night, and in a number of instances I have been rewarded by a rapid return of hair in these bald areas. In other cases I have used treatment of a more stimulating character, such as applications of chrysarobin, phenol and the high-frequency current, but I was surprised to observe that my results were more rapid and satisfactory from use of the milder methods. This would suggest that alopecia areata may be of seborrheic origin since the two affections are so frequently concurrent and both yield to the same treatment.

DR. FRANK C. KNOWLES, Philadelphia: In anticipation that Dr. White would dwell on the subject of alopecia areata, I have reviewed the dispensary reports of four hospitals, the Pennsylvania, University of Pennsylvania, Howard, and Children's, with which I am connected. During the last five years I have seen 105 cases of this disease, twelve of this number being of the universal type. Alopecia areata of dental origin has recently been reported by several writers; Jacquet has written most extensively on this phase of the subject.

Rousseau-Decelle (*Bull. et mém. de la Soc. méd. des hôp.*, 1909, p. 62) has described several cases. Jourdanet (*Bull. de la Soc. française de dermat. et de syph.*, April, 1910), detailed an alopecia areata of the nape of his own neck following caries of a wisdom tooth. Traumatism seemed to have been etiologic in a few of my cases. In my collection of photographs are five pictures of a case of universal alopecia, in a boy of sixteen. The various stages and relapses of the disease, extending over a period of three and one-half years, are plainly shown. The last photograph, which was taken in May, 1910, shows complete restoration of all the hair.

DR. J. M. KING, Nashville: Dr. Whitfield, of King's College, London, who has the reputation of being a very careful and competent observer, has found some defect of vision in nearly all his patients with alopecia areata. I remember that whenever such a patient consulted him, he always had the vision tested. In treatment, the prescription that I have used, in alopecia of the seborrheal type has been made up of bichlorid of mercury, resorcin, chloral hydrate, tincture of cantharides, glacial acetic acid and alcohol. I first saw this used in St. George's Hospital, London, and I found that it acted very well indeed in a number of cases. I have not tried euresol, as this mixture has served me well in conjunction with sulphur ointment, used once every week or two weeks, the night before the application of green soap shampoo.

DR. ALFRED SCHALEK, Omaha: I was surprised to hear that seborrhea was an incurable disease, as my experience has not borne that out. I believe that it is curable in the majority of cases if the treatment is sufficiently prolonged. In one case of alopecia areata in which I applied the high-frequency current, the coincident seborrhea of a severe type from which the patient was also suffering largely disappeared, and from that time on I have used the high-frequency current in these cases with good results.

DR. J. B. KESSLER, Iowa City: The statement made by Dr. White that alopecia was more common in females than in males rather took me by surprise. My experience has been the reverse. In the hospital with which I am connected there are about 45 nurses in the training-school; after they have been in the hospital six or eight months many of them complain that they are losing their hair. Last summer, in connection with some of my colleagues, I took up this matter to see if the cause of this loss of hair could be determined. We investigated the cooking and the quality and quantity of the food, which was up to the average and sufficiently nourishing, and the only possible etiologic factor we could find was a lack of exercise in the open air. These nurses were on continuous duty for twelve hours and then returned to the Nurses' Home to sleep and study. It seems to me that this is the most prolific cause of alopecia in this class of people. I believe that women, as a rule, take better care of their hair than men, and when the hair becomes affected they are apt to follow the physician's directions more faithfully than men.

I have had some experience with euresol, and while it is very efficient, it is also very expensive, \$1.00 an ounce making the price almost prohibitive. I have found, usually, in these forms of alopecia, that ointments are better in the beginning than solutions, and that the latter are more effective when they are preceded by the use of ointments. A favorite application of mine—although its odor is objectionable—is the oil of cade and sulphur. I first learned the value of this mixture while I was in Boston, working under the elder Dr. White. Euresol was brought to my attention through the kindness of Dr. Charles J. White; my results with this remedy, as well as those of my son, have been very satisfactory. I keep up the application for about a month, when the dandruff can be easily removed and the scalp will remain free from it for a reasonable length of time. There are some cases, however, and I have one under my observation at the present time, in which all methods of treatment are more or less unsatisfactory.

DR. ISADORE DYER, New Orleans: I want to sound one note in the danger of the use of the hair brush. I have preached for many years that no patient with dandruff will

recover until the hair brush is discarded. There are only two ways of sterilizing it: One is by boiling and the second is by burning it. In the propagation of dandruff, the barber-shop is probably the chief offender, and I believe that an inspection of the usual ancient hair brush found in the wash-room of the country hotel or in any public place will demonstrate the destruction of the bristles of the brush itself by the micro-organism. The men who are interested in the work of this Section, as well as all dermatologists, should carry on this crusade against the hair brush as I have long done in my own city. I have frequently seen patients in whom the recurrence of dandruff invariably followed a visit to the barber shop. While on a visit aboard, after I had been free from dandruff for many years, I visited a barber shop and warned the barber not to use the brush. Just as he was completing his work, however, he forgot my instructions and gave one stroke with the hair brush. Five days later I again began to treat my scalp for dandruff. I cannot concede that the particular form of seborrhea which we call dandruff is incurable. I instruct male patients to wash their scalp every day; the female patients every other day, or at least twice a week. An experience extending over a number of years, has justified my faith in the use of resorcin, 2 to 5 per cent. solutions. Euresol has no advantage over this, in my own experience. In fair-haired patients, or those who have hair tinged with gray, the resorcin must be modified or some substitute employed. By neglecting this precaution, I have once or twice in my early experience inflicted on my patients hair which in color resembled the plumage of a canary bird. Chloral hydrate serves in these cases: it is an excellent stimulant to the scalp and an efficient antiseptic. I have never seen a case of alopecia areata which I believed to be parasitic, or in which I was not able to demonstrate a neurotic basis. I remember one case in which these bald patches recurred for nearly a year; the patient's occupation was that of a driver of a fire engine, and when he gave that up, his hair promptly and permanently returned.

In the treatment of this condition, I regard the high-frequency current as more satisfactory than any other.

DR. M. L. HEDINGSFELD, Cincinnati: The basis of our present treatment of alopecia rest on the experiments of Lassar and Bishop, which were carried on 30 to 40 years ago on mice, rabbits and other animals. For fifteen or 20 years the results of this work were unquestioned: when they were controverted by Blaschko, who maintained that alopecia was not a parasitic condition. Blaschko carried out a series of experiments similar to those of Lassar and Bishop, and his results were absolutely negative. Treatment of this condition at the present time is based largely on the theory that it is of parasitic origin. Personally, I concur in the belief that premature baldness is not a parasitic condition. I think that too much manipulation of the scalp by rubbing and massaging is injurious both in men and in women. Premature baldness is accompanied by four cardinal symptoms, i. e., itching, dandruff, a dry or oily condition of the scalp, and, lastly, loss of hair. Dandruff is only a precursor of the loss of hair, and in order to prevent the occurrence of the latter, we must control the itching, the dandruff and the abnormal condition of the scalp. Treatment must be directed against these special conditions. Resorcin, if too strong or too frequently applied, will produce an oily condition of the scalp. An oily scalp may be rendered less oily, or even dry, by substituting colloidal sulphur or nascent sulphur, after the formula of Radcliffe Crocker for the resorcin.

DR. WILLIAM FRICK, Kansas City: In the alopecia accompanying syphilis the loss of hair is not always limited to the scalp. I recently saw a case in which the alopecia of the scalp was not complete, but there was a complete loss of the eyebrows and eyelashes.

DR. WILLIAM A. PUSEY, Chicago: One factor in regard to alopecia has not been mentioned and is worthy of consideration, particularly with the present fashion, and that is, excessive exposure of the scalp to sunlight. We are all familiar with the middle-aged man riding horseback or playing golf bareheaded in the forlorn hope of bringing his hair back. For many years I have regarded this excessive exposure

ure to sunlight as an exciting factor in the production of alopecia. I have noticed that many of these patients apply for treatment in the autumn, after they had gone bare-headed throughout the summer, and I was also led to this idea through the analogy of the effect of the sun's rays with those of the x-rays. We know that with highly actinic energy we can produce baldness, and I am inclined to believe that free exposure to sunlight will have the same effect. This is probably only one of many factors, and in my opinion alopecia is a condition of complicated etiology; it is not a well-grounded view that all alopecias or nearly all are parasitic.

I have never been able to convince myself of the value of many of the remedies that have been mentioned in the treatment of this condition. This is true of resorcin, with which I have had a very unsatisfactory personal experience. I know of only two remedies that have a definite value in the treatment of alopecia, namely, tar and sulphur. I have used alcohol in various combinations, and it is my impression that about as much good is accomplished by alcohol alone as when it is combined with other remedies.

DR. J. GRINDON, St. Louis: It is a popular notion that frequent washing injures the scalp, but practically, I have observed that those who are the most inveterate and constant in the practice of washing the scalp keep their hair as long as anybody else, and I always tell my patients that they can wash their heads as often as they please. Nor can I understand how the application of soap and water to the surface of the scalp can have any bad effect on the growth of the hair. In regard to medication in these cases, I have had very good results from the use of resorcin, and I agree with Dr. Kessler that solutions are usually more effective when they are preceded by the use of ointments. One of my favorite prescriptions is composed of petrolatum, salicylic acid and sulphur. I tell my patients that this application is disagreeable, but that it will probably not be necessary to continue it for longer than a month. After this I use resorcin, usually a 2 per cent. solution, either alone or in combination. In cases of well-established seborrheal alopecia I tell my patients that I do not believe that I shall ever be able to give them an actual permanent cure, but that I hope to bring about a symptomatic cure, providing they keep up the treatment indefinitely. As long as they live they will be obliged to pay some attention to the scalp in order to avoid a recurrence. So far as the effect on the scalp of exposure to the rays of the sun is concerned, I must agree with Dr. Pusey on theoretical grounds. The comparative frequency with which cases of loss of hair are observed in the autumn I attribute not to the effect of the sun's rays, but rather to the fact that there is natural loss of hair at that period of the year, whether one plays golf bareheaded or not. The x-ray, in small doses, causes a growth of hair, while large doses produce a loss, and the actinic rays from the sun in such doses as we get them, probably stimulate the growth of hair. Our ancestors, who wore no clothing at all, had hair all over their bodies.

DR. J. B. KESSLER, Iowa City: I have in mind a case of universal alopecia in a boy of 18 in whom the condition has now lasted about 2 years. With the exception of two or three little stubs, his body and scalp are completely bare. He has been examined by a neurologist and his blood has been examined with entirely negative results. I have been unable to find the cause of the alopecia or a remedy for it.

DR. FRANCES ROWLEY, Galveston: Has anyone studied this matter with reference to the diet of the patient? Has the nitrogenous metabolism been investigated, or would these patients receive any benefit by increasing the sulphur?

DR. C. J. WHITE, Boston: The diversity of opinions expressed well illustrates the fact that we really do not know anything about this subject scientifically. We have our pet theories, and we reason largely by analogy. I agree with Dr. Pusey in regard to the effect on the hair of over-exposure to sunlight. I believe that the scalp and hair are supposed to have a certain amount of grease, and if we expose the scalp to the sun, we remove the greasy element and the hair becomes bleached. For the same reason, constant washing of

the head or over-treatment of the scalp is equally disadvantageous. This history of too much sun or too much washing I have frequently obtained from persons who were prematurely bald.

My colleagues and I in Boston have never derived much benefit from the use of resorcin in this disease. If it is applied strong enough to do any good, it inflames the scalp. As to a possible deficiency of sulphur in the economy, to which Dr. Rowley referred, I do not know whether any scientific work has been done in that direction, but I have given that drug internally in one of its several forms without resulting benefit.

I tell my patients to use a hair brush as little as possible unless it is a clean one, and instruct them to sterilize it by placing it in the sun for a few hours at least once a week. I agree with Dr. Dyer that the hair brush is a very common cause of the persistence of dandruff. In treatment in general, I have tried all the various ointments, and in my hands they did not work so well as the two lotions that I have described. I believe that women are affected with alopecia oftener than men, but there are cases in which men feel more keenly than women the loss of their hair. As to the various etiologic factors of alopecia areata referred to by Dr. Knowles, I do not think we know the true cause of the affection, but I believe that in some specific organism plus the stimulus of a nervous breakdown or sudden shock or the debilitating effect of slow sepsis from carious teeth we have a reasonable theory of the origin of this disease.

THE EXTERNAL PREPARATIONS OF THE U. S. P. AND THE NATIONAL FORMULARY *

C. S. N. HALLBERG, Phm.D., M.D.
CHICAGO

THE U. S. PHARMACOPEIA

The external preparations of the U. S. P. comprise some 55 articles representing the following classes:

Unguenta	Linimenta
Cerata	Colloidia
Suppositoria	Cataplasmae
Oleata	Chartae

Previous to the last revision these preparations were designed from a purely pharmacal standpoint: that is, the selection of the vehicle—the forming substance—was governed primarily by pharmaceutical considerations, so as to insure stable and otherwise superficially satisfactory preparations.

Having immediate charge of these preparations in the last revision, it was our good fortune to receive suggestions from many medical specialists, ophthalmologists, gynecologists and dermatologists, such as Dr. W. L. Baum of this Section, and the formulas for these preparations were for the first time revised on a therapeutic basis. Since they have proved uniformly satisfactory pharmaceutically, it might be well here briefly to consider these preparations according to their classification and therapeutic groupings, in order to determine whether practice has demonstrated the correctness of the theoretic considerations on which they were severally formulated, and it is hoped that the fullest discussion and criticism may obtain among those who use these preparations.

* The author of this paper, being now engaged in the revision of the U. S. P. and the N. F., desires physicians to report to him any criticism on these preparations, particularly the newer ones taken from the British Codex, and also any additions that might be sufficiently valuable or extensively used to warrant admission to either the U. S. P. or the N. F. Address C. S. N. Hallberg, 74 E. Twelfth Street, Chicago, Ill.

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

UNGUENTA—OINTMENTS

Impalpable mixtures of medicinal agents and a fatty vehicle, soft solids, melting at the body temperature, intended for external application or inunction. They may be grouped therapeutically according to the function of their respective vehicles:

1. *Epidermatic*.—Non-penetrative, non-absorptive, protective, antiseptic, etc.

Vehicles: Soft paraffin (petrolatum, etc.).

PREPARATION	PRINCIPAL INGREDIENT	PROPORTION
Unguentum acidi borici—	boric acid	10%
phenolis—	phenol (carbolic acid)	3%
zinci stearatis—	zinc stearate	50%
hydrargri diluti—	mercury	33%

2. *Endermatic*: Semipenetrative or semiabsorptive emollient, nutritive, astringent, etc.

Vehicle: Animal or vegetable fats, oils or waxes—lard, suet, almond oils, hydrated wool fat.

PREPARATION	PRINCIPAL INGREDIENT	PROPORTION
Unguentum acidi tannici—	ac. tannic,	20%
aquæ rosæ—	rose water,	20%
belladonna—	ext. belladonna,	10%
chrysarobini—	chrysarobin,	5%
diachylon—	lead plaster,	50%
hydrargyri—	mercury,	50%
hydrargyri nitratis—	mercury nitrate,	10%
iodi—	iodin,	4%
iodoformi—	iodoform,	10%
picis liquidæ—	tar,	50%
potassii iodidi—	potass. iodid,	10%
stramonii—	ext. stramoni,	10%
sulphuris—	sulphur, washed,	15%
veratrinæ—	veratrin,	4%
zinci oxidi—	zinc oxid,	20%

Vehicle: Hydrated wool fat and petrolatum, equal parts.

Unguentum hydrargyri ammoniati,	10%
hydrargyri oxidi flavæ,	10%
hydrargyri oxidi rubri,	10%

3. *Diadermatic*.—Penetrative or absorptive—systemic or constitutional.

Vehicle: Hydrated wool-fat:

Lanoleum hydrargyri—50 per cent., not official.

CERATA—CERATES

Mixtures of fats, waxes, sometimes resin, of hard consistency, softening by heat, readily spread on cloth, adhering to the part applied. To serve as protective dressing or to produce antiseptic, astringent or vesicating effects.

PREPARATION	PRINCIPAL INGREDIENT	PROPERTY
Ceratum—		protective.
camphoræ—	linim. camphor,	10% antiseptic.
plumbi subacetatis—liq.,	20%	astringent.
resinæ—		discutient.
resinæ compositus—		discutient.
cantharides—	32%	vesicant.

EMPLASTRA—PLASTERS

Mixtures of medicinal agents with lead plaster, rendered pliable by admixture with rubber, hard solid, readily softening so as to be spread on cloth or fabric, adhering to the skin-part to which it is applied. To serve as protective or supportive or to exercise specific effects.

PREPARATION	PRINCIPAL INGREDIENT	PROPERTY
Emplastrum plumbi—	diachylon, lead oleate.	
adhesivum—	rubber, petrolatum,	2% anodyne.
belladonna—	ext. belladonna,	30% rubefacient.
capsici—	leoresin capsicum	alterative.
hydrargyri—	mercury,	33% anodyne.
opii—	ea. opium,	6% stimulant.
saponis—	sona	10%

The plasters of the present Pharmacopeia, all containing adhesive plaster as the vehicle, easily prepared and readily spread, are a vast improvement over the former "pitch plasters." Being endermatic, they exert the action of the respective medicinal agents, in which respect they differ from the commercial rubber plasters which are simply adhesive, do not permit any penetrative effect and are therefore therapeutically inert.

SUPPOSITORIA—SUPPOSITORIES

Mixtures of the medicinal substances and a fatty or gelatinous vehicle readily fusible at the body temperature and made into different shapes for introduction into the various orifices of the body.

Three different kinds as to size and shape of suppositories are official.

1. *Rectal*.—Cone-shaped, weighing 2 gm.; vehicle theobroma oil.

2. *Urethral*.—Pencil-shaped, weighing from 1 to 2 gm.; vehicle glycerinated gelatin or theobroma oil.

3. *Vaginal*.—Subglobular or ovoid, weighing from 4 to 10 gm.; vehicle glycerinated gelatin or theobroma oil.

There are, besides, glycerin suppositories gelatinized by soap to permit of being made into dosage form for facile introduction in the rectum, there to act as a solvent and thus produce prompt evacuation. The true suppositories, on the other hand, being analogous to ointments or cerates, present to the surfaces the most intimate admixture of the various antiseptic, astringent, anodyne, etc., agents for the most favorable action on the parts to which applied.

While the selection of theobroma oil as a vehicle for rectal suppositories cannot be improved on, a non-fatty vehicle is preferable for those intended for urethral and vaginal use. Glycerinated gelatin is therefore given the preference, although the choice of also using theobroma oil is left free to the practitioner.

The reason for this distinction in the vehicle for these different kinds of suppositories is based on the information of clinical observers that, while the rectal secretions are normally alkaline and therefore a fatty vehicle is appropriate, the secretions of the genito-urinary organs being normally acid, a fatty vehicle would be less desirable and hence the choice of a non-fatty vehicle would be better adapted to the mucous surfaces under such conditions.

The choice of glycerinated gelatin for this purpose leaves nothing to be desired from a pharmaceutic standpoint, the suppositories being soft and flexible and owing to the great proportion of glycerin contained (about 50 per cent.) retaining their solubility for any reasonable length of time. With the use of the official gelatinum glycerinatum, these suppositories are readily and quickly prepared, the only requirement being the variously shaped molds.

Whether or not this distinction in vehicle in the different kind of suppositories is really of therapeutic advantage has not been so far generally demonstrated, since seldom is any other vehicle than theobroma oil specified, no matter what kind of suppositories are required. It is hoped that this question will be discussed so that the Committee on Revision will have the benefit of the experience of clinicians.

OLEATA—OLEATES

The official oleates are formed by direct union of the base with oleic acid. They belong to the so-called "insoluble soap." To the best of our knowledge oleates are only endermatic and not diadermatic; that is, they penetrate into the skin but do

not pass through so as to have systemic effect. The following official are saturated oleates:

Oleatum hydrargyri—(25 per cent. Hg oxid).

Oleatum quiniæ—(25 per cent. quinin alkaloid).

The following are solutions of alkaloidal bases in oleic acid in excess. In the first three olive oil is substituted for about one-half the amount of oleic acid. The advantage of this has been questioned and deserves clinical observation.

Oleatum atropinæ.	2%	Oleatum veratrinæ.	2%
Oleatum cocainæ.	5%	Oleatum aconitinæ.	2%

Zinc oleate is a fine dry powder of a soapy feel valuable as a mild antiseptic and astringent "dusting powder."

COLLODIA—COLLODIONS

Solutions of medicinal substances in collodion, a solution of pyroxylin in ether-alcohol, which being applied with a pencil quickly dries and leaves an impervious film.

The following are official:

Collodium—	collodium flexile—	
acidi tannici—	(styptic),	20%
cantharidatum—	(blistering),	60%
iodatum—	(iodized),	5%
collodium iodoformatum—	(iodoform),	5%
salicylatum comp.—	(corn collodium),	
tigli—	(croton oil),	10%

THE NATIONAL FORMULARY

While not so important a work as the U. S. P., the National Formulary contains many preparations extensively used by physicians; and now is the time to make such additions and corrections as may be advisable, since its revision is now proceeding.

The following several classes of preparations for external or local use are included and it is the desire of the Committee to be informed by physicians of what criticism they would make on these various formulas; also what other preparations they would propose for admission.

GLYCEROGELATINA—GLYCERO-GELATINS

Medicinal agents incorporated with a 25 per cent. solution of gelatin in glycerin. Especially useful as a dressing where bandages are inadmissible. Prepared from the official gelatinum glycerinatum by simply incorporating the medicinal agent, first levigated with glycerin, with the melted glycerogelatin. The jelly is melted by placing the container in hot water, when it is applied with a camel's-hair pencil.

Glycerogelatinum—	acidi salicylici,	10%
	iodoformi,	10%
zinci durum—	firm zinc glycerogelatin.	
zinci mollis—	soft zinc glycerogelatin.	

PASTA DERMATOLOGICA—DERMATOLOGIC PASTES

Ointment-like mixtures of starch, dextrin, zinc oxid, calcium carbonate or sulphur, made into a paste with glycerin, soft soap, petrolatum, lard or other fat, with antiseptic or astringent agents.

Pasta dextrinata—Equal parts dextrin, glycerin and water.

ichthyoli—	Unna—ichthylol,	25%
naphtholi—Lassar—	beta-naphthol,	10%
resorcinolis mitis—Lassar—	resorcinol,	10%
zinci—Lassar—	zinc—salicyl,	2%
zinci mollis—Unna—	soft zinc paste.	
zinci sulfurata—Unna—	sulphur præcip.,	10%

STILI DILUBILIS—UNNA PENCILS

Stilus acidi salicylic dilubilis,	10 per cent.
Stilus cocainæ dilubilis,	5 per cent.

UNG. RESORCINI COMP.

This ointment, containing resorcinol, zinc oxid and bismuth subnitrate, each 6 parts, and oil of cade 12 parts, is extensively employed. The preparation discolors, but when the oil

of cade is replaced by oil of birch (ol. rusææ) 6 parts (instead of 12 parts) a superior ointment is obtained. The opinion of physicians is decided on this.

UNGUENTA EXTENSA—SALVE-MULLS

Medicated cerates to be spread on gauze for continuous application to avoid maceration.

Ung. extensum zinci,	10%
hydrargyri chloridi corrosivi,	2 per mille
salicylatum,	10%
creosoti salicylatum.	

The following ointments of the British codex may also be of service:

Unguentum capsici (24 per cent. capsicum infused).
creosoti, 10 per cent. petrolatum.
suprarenalin, 10 per cent. suprarenalin.

Petrolatum combined with ammonia soap is used as a vehicle under the following titles:

Petrolatum saporatum liquidum—liquid petrox.
Petrolatum saporatum spissum—solid petrox.

These are rarely used except as vehicles for various potent agents; iodine, phenol, etc. The Latin title is unwieldy and becomes more so when linked to a specific name.

PAROGEN

Under the title "Parogen" the British Codex contains the following formula containing 50 per cent. less liquid paraffin (liquid petrolatum) than that of the present N. F.

Parogenum—parogen: Syn. liquid parogen; vaso-liniment; oxygenated paraffin. Liquid paraffin 40; oleic acid 40; alcohol ammon. (5%) 20. Mix and agitate until a clear solution is obtained.

Also the following combinations, all made with the liquid parogen:

Parogen chloroformi camphoratum—camphorated chloroform parogen.

Camphor 37.50; chloroform 25, dissolve, add parogen 37.50.

Parogenum creosoti—creosote parogen—

Creosote 5; parogen 95; mix them.

Parogenum empyreumaticum—empyreumatic parogen.

Oil of cade 25; parogen 75; mix them.

Parogenum eucalyptolis—eucalyptol parogen.

Eucalyptol 20; parogen 80; mix them.

Parogenum guaiacolis—guaiacol parogen.

Guaiacol 20; parogen 80; mix them.

Parogenum hydrargyri—mercury parogen.

Mercury 30; wool fat 15; triturate till metallic globules cease to be visible, then add thick parogen, 55.

Parogenum ichthamolis—ichthamol parogen.

Ammonium ichthosulphonate 10, parogen to 100, dissolve and strain after standing.

Parogenum iodi—iodine parogen.

Iodin 10; powder and triturate till dissolved in oleic acid 40; mix with liquid paraffin 40 per cent, then alcohol ammon. (5 per cent.) 10.

Parogenum iodi dilutum—diluted iodine parogen.

Iodin parogen 60; parogen 40; mix.

Parogen iodoformi deodoratum—deodorized iodoform paraffin.

Iodoform 3, eucalyptol 3, parogen to 100. Dissolve iodoform in the parogen by warming cautiously; then add the eucalyptol.

Parogenum mentholis—menthol parogen.

Menthol 2, parogen to 100; dissolve by warming cautiously.

Parogenum naphtholis—naphthol parogen.

Naphthol 10; parogen to 100; triturate till dissolved.

Parogenum picis—tar parogen.

Tar 25, parogen to 100; mix them.

Parogenum salicylatum—salicylated parogen.

Salicylic acid 10, parogen to 100; powder and triturate till dissolved.

Parogenum sulphuris—sulphur parogen.

Sulphur subl. 3, linseed oil 37; dissolve by aid of heat; then mix with parogen to 100.

Parogenum sulphuris compositum—compd. sulphur parogen.

Sulphur parogen 10, oil of cade 10, thymol 0.3, eucalyptol 3, oil of turpentine 30, parogen to 100. Dissolve the thymol and eucalyptol in the oil, mix with the parogen.

Parogenum terebinthina—turpentine paraffin.

Venice turpentine fact. 20, parogen to 100; mix them.

Parogenum spissum—thick parogen.

Hard paraffin 12, liquid paraffin 48, oleic acid 30, alcohol ammon. (5 per cent.) 10. Melt the hard paraffin; add the liquid paraffin, then the oleic acid and the alcohol and continue the heat on a water-bath until the product weighs 90.

The following single generic names are suggested for the same reasons as was the parogenum for petrolatum saponatum. If physicians are expected to use these preparations, the generic titles must be composed of single words otherwise when the specific name is added they become too cumbersome.

LANOLIMENTA—LANOLIMENTS

Lanolimentum mentholis—menthol lanoliment.

Menthol 5, hydrous wool-fat to 100; mix.

Lanolimentum mentholis salicylatum—salicylated menthol lanoliment.

Menthol 5, methyl salicylate 10, hydrous wool-fat to 100; mix.

Paraffinoleum mentholis—menthol paraffinol—liquid petrolatum and menthol.

Menthol 2, liquid petrolatum to 100. Mix and strain if necessary.

Paraffinoleum eucalypti—eucalyptus paraffinol.

Oil eucalyptus 5, liquid petrolatum to 100; mix.

Paraffinoleum thymolis—thymol paraffinol.

Thymol 1, liquid petrolatum to 100. Dissolve by trituration in a warm mortar.

Paraffinol phenolis—phenol paraffinol.

Phenol cryst. 1, liquid petrolatum to 100. Dissolve by trituration in a warm mortar.

74 East Twelfth Street.

MEDICO-PHARMACEUTICAL ETHICS *

A. S. MUSANTE, PH.G., M.D.

SAN FRANCISCO

The heading of this paper sounds more like the title of a book on the subject than that of a more or less haphazard essay, but no other short caption suggested itself for a treatise on the proper attitude and mode of reciprocal action that should exist between the members of the professions of medicine and pharmacy.

No historical survey of the origin of either one of these callings from the other will be attempted, for some medical writers declare that pharmacy originally sprang from the forced surrender of the custom of primeval healers of preparing their own drugs, in order to keep abreast of more related advances of their work, and the pharmacists retort that there were no doctors at first, the healing art having been practiced by the ancient botanists, from whom pharmacy, more than medicine, can claim heritage. Nor will the subject be treated academically. An effort will be made to point out and describe some of the real and imaginary evils that have crept into the practices of medicine and pharmacy, which make pharmacists and physicians antagonis-

tic professionally to one another, and to suggest how these unethical errors can be corrected.

COMMON VICES

I shall get at the substance of the matter instantly by stating that there are some evils that are common to both professions, among which may be mentioned, first, the payment of percentages by pharmacists and physicians for patients referred; second, the recommendation of a certain physician or drug-store because of this commission; and, third, the expression of derogatory opinions against the members of the medical and pharmaceutical fraternities, because of the facts that, on the one hand, the physician in question will not send patients or pay the commissions others do, and, on the other, the pharmacist is not one from whom the physician can expect a percentage from his prescriptions.

There is only one side to the first of these three evils and that is this: The payment of a percentage by a pharmacist to a physician for prescriptions directed to his store is wrong, as it is practically collusion between the prescriber and dispenser in an effort to overcharge the patient. It only means that the patient is going to be forced to pay an additional amount to cover the commission paid. A physician should charge a sufficiently remunerative fee to satisfy himself financially and should not expect in addition a share of what the patient is paying (supposedly) for his medicine. It is equally unjust for the pharmacist to expect a commission for work referred to the physician, as this recommendation would then be made mostly for gain and, in this way, only physicians paying this commission, rather than those who are capable, would be named to the inquiring. The recommendation of a certain physician by the pharmacist should always be made because it is thought that that physician is the best fitted to advise the patient; and the medical man can feel justified in referring the sick to particular drug-stores only when he is of the opinion that in these places his prescription will be more accurately filled than in other pharmacies; in this way using his expected care that incompetent men will not be given a chance to make any errors.

The last of these common faults, that of making belittling remarks about either certain physicians or certain druggists who do not further the interest or meet the approbation of a member of either profession, is wrong because the physician or pharmacist often is mistaken in his opinion, and, again, because it may shake the confidence of a patient in his physician when the latter is censured and therefore tend to lessen the likelihood of the patient's cure. As pharmacists or physicians, we should not speak against one or the other. We can and should refuse to recommend to patients anyone who is incompetent, but should not speak evil of him. We only nullify each other's efforts in performing the noble work of aiding the sick when we speak against members of either profession. Let us recommend certain physicians or certain pharmacists when asked or when we think it necessary; but let it always be for meritorious reasons and never with the consideration of possible gain or revenge in view. In this way, each will reap his just reward and medicine and pharmacy will move on, hand in hand, in the work of humanity to which they should be devoted.

Let us now take up the consideration of evils confined almost entirely to one or the other profession, and we shall find much to speak about. The pharmaceutical evils are principally drug-store prescribing, substitution, the pushing of patent medicines, bad dispensing, and

* Read at the Annual Meeting of the California Pharmaceutical Association, San Francisco, May 19, 1910, at which the San Francisco County Medical Society was

the practice of exposing mistakes supposed to have been made by prescribers. The medical profession is called on to defend itself against the charges of dispensing medicines, deficient knowledge of material medica and prescription-writing, which is responsible for the ordering of unsightly mixtures, overdosage and the prescribing of patent and proprietary medicines, as well as special makes of official preparations, and the custom of blaming the pharmacists for failure to obtain certain therapeutic results, a supposed color, odor or taste of a mixture prescribed. These topics cover the sources of complaint usually found when a threatened breach is wedging in between the professions, but do not include matters that often cause internal dissension between pharmacists themselves, like higher educational requirements, cut-rate methods and side-lines; or matters confined within medical ranks, such as advertising and specialization; or the subject of renewals of prescriptions, the ownership of the latter and the matter of the enforcement of the pure drug acts, which are regulated by law in many states.

PHARMACEUTIC TRANSGRESSIONS

Taking up the pharmaceutic vices, one by one, let us define them and see how far—if at all—they are permissible, and offer some suggestions for their correction or regulation.

Drug-Store Prescribing.—In the literature and by personal experience, I find that most of the antagonism felt toward the pharmacist by medical men is on account of drug-store prescribing, which includes treatment over the counter and in the back room. That it is wrong even to the patient, for the prescriptionist to attempt to diagnose or cure diseases, either by prescribing medicines or by giving treatments, as in the form of irrigations in venereal diseases, there is no doubt. The argument often advanced that this practice results in a financial loss to the physician as well as to the druggist, is not the strongest objection to this evil. For no one who realizes how difficult it often is for the skilled physician to diagnose and treat the symptoms of which the average patient complains can fail to see how impossible it is for the pharmacist, who has received no special training in these matters. Consider how misleading a symptom must be to one who knows nothing about reflected pain or who has never heard of an extra-uterine pregnancy! "But," some will say, "that does not apply to diseases which are self-evident, as for example, gonorrhea or syphilis." It does not make any difference, for it is often just as hard to treat these diseases successfully as it is to diagnose others. This statement is borne out by the experience of eminent gynecologists who have found that about 12.5 per cent. of all operations performed on women are caused by uncured gonorrhea affecting their husbands, who often were assured that they were cured and also by the startling fact that this disease is responsible for 80 per cent. of deaths from disorders peculiar to women.

But how far can the pharmacist go before he can be deemed guilty of intruding on the physician's domain? This is a limit on which not all agree. Some say that a prescriptionist should never give medicine without an order from a physician, but is this practical? It seems that the best compromise that has been offered is that a pharmacist should never try to diagnose a case, but should explain to a patient that the best thing would be to see a physician, as his opinion may be necessary, and then, if the customer refuses to do this, the druggist should give some unharmed mixture for the symp-

tom complained of with final directions to see a physician if not relieved. A member of the pharmaceutic profession is presumptuous when he fails to tell the sick that pharmacists are not able or taught to diagnose diseases and that it is the physician's work to do so, just as it is presumptuous for the physician to give a price on prescriptions without knowing how they are figured.

Substitution.—Substitution or omission of ingredients in a prescription is unjustifiable and criminal. The physician and patient have a right to insist that the medicines prescribed are dispensed and anyone who wilfully deals out one substance for another or who leaves out any of the contents ordered in a prescription is deserving of the bitterest condemnation from both professions. But there is an aspect to this subject not often considered by my exacting colleagues, and that is the custom of specifying the manufacturer's name when official preparations are prescribed. In rare cases this is along the lines of safety, but it can and is often carried out too far. For example, let me tell a story which Prof. W. M. Searby narrated to me, touching on this point. A pharmacist who had a large number—I think it was fifteen—fluidextracts of ergot, was handed a prescription in which a new inferior make was specified. This was an urgent case and the medicine was needed, for the messenger said the physician was waiting to use the ergot on the patient, who was suffering from a post-partum hemorrhage. So the pharmacist gave an excellent preparation of the drug instead of the one called for, which he did not have. Was he right in what he did? He certainly was, for it might have been the cause of a woman bleeding to death if, actuated by exaggerated ideas of avoiding substitution, he had given back the prescription and not dispensed what he did. Many other cases like the above happen and a drug-store must be kept stocked with many makes of certain preparations which are exactly the same in value. It would be better for physicians to specify the maker's name only when there is some good reason, leaving the pharmacist, who is better trained to choose between good and bad preparations, responsible for the quality of all drugs, as he is for ingredients of unspecified manufacture.

Crude Dispensing.—By the evil of bad or crude dispensing is meant the turning out of mixtures of offensive appearance and taste and doubtful therapeutic value because of inability to compound properly. Every physician has noticed this fault when for some reason he has had to write some prescription, not simple to dispense, a second time for the same patient, who has gone to a different pharmacist each time. I am not referring to those cases in which the trouble is due to the inability of the physician to prescribe, but to those instances in which in one drug-store the pharmacist will understand how to combine the ingredients ordered and turn out an excellent preparation, while at other places the compounding is done by men who do not know the proper way and hand a patient an abominable combination. So much for bad dispensing.

Exposing the Mistakes of Physicians.—This is just the course which the pharmacist should not take, considering how human it is to make blunders, especially in the crucial situations in which the prescriber often finds himself. Neither by word nor by sign should the patient know of any supposed error, but the pharmacist should communicate with the physician about the matter and, if this is not possible, the correction should be made by the prescriptionist and the physician be positively informed. It is wrong to be apathetic and to return the prescription, as the mistake might be overlooked in

another place and a fatality result. It follows that a physician should always act in a gentlemanly manner when called on to correct a mistake, and should feel that a dispenser is acting along the lines of carefulness and safety in communicating with the physician even if the error can be shown to be only apparent.

Pushing the Sale of Patent Medicines.—The matter is one almost wholly pharmaceutic. Let us pass it by thus: Most of the prominent pharmacists would gladly do away with this feature of their business if it meant the abolishment of the public evil of self-medication, but, as it would be taken up by department-stores and the business increased rather than lessened, there is no reason why they should not keep these nostrums. When it is considered also that often even physicians prescribe these remedies, it seems unreasonable to expect a drug store to do without them. I believe, however, that the pharmacist should never recommend any of these preparations, but should furnish them only when called for. For druggists to push certain compounds of their own manufacture, like insect-destroyers and spring medicines for which customers rarely apply to a physician, is not much of a breach, especially when those are recommended to be "just as good" or better than widely advertised, but not so effective, nostrums. Care in proclaiming the virtues of these preparations should be exercised and no exaggerations indulged in that might offend broad-minded and intelligent physicians—no matter how great an impetus would be given to these goods.

MEDICAL EVILS

And, now, let us review the transgressions of which the medical profession seems to be guilty and reason out how much can be said to be excusable.

Dispensing by the Physician.—Dispensing at the office and at the patient's house is the oldest charge hurled at physicians. Let it be understood at the start that no reasonable pharmacist can deny that this practice is in order when immediate medication is needed or when the patient lives at a distance too remote from a drug-store. It was said in defending the physician against exposure of his errors that the nature of his work is such that mistakes often creep into his prescriptions; therefore the fact is evident that somebody must act as a checker in dispensing his orders, and who is better qualified than the pharmacist? Many times also the physician is wrong in his idea of the dosage of some powerful drug appropriate for the occasion, but rarely used, and it is here that the knowledge of posology taught in the college of pharmacy should be brought into play. The pharmacist also has a better opportunity to make sure, as he can look these matters up in the books on materia medica without exciting suspicion. It follows also that the physician cannot dispense as competently as the pharmacist, whose ability to do so is dependent on his knowledge of and experience in mixing drugs. Therefore, a physician who makes it a practice to dispense his own prescriptions acts detrimentally to his patient, the pharmaceutic profession and his brother practitioners, in the latter case because of the unfair financial advantage gained by the custom.

Inability to Prescribe.—The inability to prescribe properly demonstrated by so many physicians is due to insufficient knowledge and practice in materia medica and is fundamentally responsible for its sequel, the ordering of proprietary and patent medicines. It probably would result in making better therapists—

though not as scientific laboratory men—if medical colleges would encourage prospective medical students as much in taking a course in pharmacy as a pre-medical study as they do in the completion of a purely scientific curriculum, the substance of which is hardly ever used by the average practitioner.

Illegible Writing.—That the notorious habit of prescribers of writing illegibly has not been responsible for more trouble is due to the extraordinary skill with which the pharmacists decipher the different parts of prescriptions. This subject has received legal attention in some countries, and carelessness in ordering has been made a crime.

Overdosage.—Overdosage and the writing of freakish physical and chemical incompatibilities only serve to bear out what was said about the limited idea of materia medica and pharmacy retained by medical men from the teaching given in these subjects at most medical colleges. As better courses in these subjects are being given now than five years ago, the reform in this deficiency is bearing fruit.

Prescription of Proprietary or Patent Medicines.—The use of ready-made proprietary or patent medicines has already been well thrashed out and will not receive the attention here it otherwise would. As this largely results from not knowing how to combine the remedies desired in a particular case in the most palatable and compatible form, it has decreased as the movement for a better knowledge of materia medica has progressed. This movement will spread until every physician will have a better idea of the drugs contained in the United States Pharmacopeia and National Formulary, using other drugs only when a real improvement of benefit to his patient is exploited. How few of the proprietaries of the last decade really were the products of advanced pharmacy, and how many were only well-known and often worthless drugs, done up in an elegantly deceiving style! In any of the big prescription pharmacies one will find dozens of preparations that once reigned supreme in their separate fields and are now condemned to the oblivion of the top shelves or the back room. In speaking of substitution the often unnecessary habit of specifying the maker's name when an official preparation is wanted was commented on sufficiently.

Exposing Mistakes in Dispensing.—Reciprocally the same feeling should manifest itself when the pharmacist is thought to have made a mistake in the dispensing of a prescription as was mentioned in discussing the delicate way a physician's error should be called to his attention by the prescriptionist. If a medicine has not the desired effect or does not come up to expectations as to palatability or appearance, the blame is not always with the dispenser. The physician may have forgotten to order some ingredient or may have prescribed something of which he did not know the properties as well as he might. If the medical man will use his ingenuity as often as his pharmaceutic friend does, the patient will not have his confidence shaken in the latter and will probably not be as suspicious of the physician himself. Neither the pharmacist nor physician should forget the just defenses of idiosyncrasy and tolerance in any case in which these seem to be the explanation of the patient's complaint against one or the other.

SUMMARY OF SUGGESTIONS

In conclusion, let the members of both professions feel the need of co-operation with each other; let pharmacists, out of consideration for their medical friends,

refuse to do something and insist on doing others, and let the latter act reciprocally. At the same time nothing should be done which is unjust to the public. Therefore the practice of paying commissions to pharmacists for work referred, or to physicians for prescriptions, should be absolutely discontinued. Recommendation of either prescriber or dispenser should always be based on merit and not on expected financial gain. Opinions derogatory to any member of either calling should be indulged in only in extreme cases.

Pharmacists should prescribe only in rare cases, including poisonings and instances in which first aid is needed before the physician arrives. Skill in dispensing should be possessed by all pharmacists and substitution never practiced. Errors on the part of physicians should be handled so that the patient does not know of them and corrections explained where the medicine is urgent and it is impossible to reach the physician. The rule in the matter of handling patent and proprietary preparations should be "Buy what is called for and sell on demand only" (Coody).

Physicians, on the other hand, should not dispense their own prescriptions, except in cases in which urgency or remoteness from a drug-store demands it; should possess a proper knowledge of *material medica* and prescription writing, and write legibly and order carefully, avoiding the unnecessary use of ready-made preparations and too extended specification of the manufacturer's name of official remedies, and should not expose to the patient blunders thought to have been committed by the pharmacist when unsatisfactory results are obtained.

Joint meetings where subjects of a kindred nature could be discussed are also advisable, so that such topics as those here suggested and others could be thrashed out.* The two professions should act in unison in the United States Pharmacopeia and

I think that, as our differences are being adjusted, we are again making it plain to the pharmacist and to the physician just where the one is intruding on the ground

of the other. There seem to be many things too often left undone that would make up for the loss occasioned by a stricter adherence to one's own work. For example, much of the laboratory work of the physician, like the examination of blood, urine, sputum and feces, could be done for him by the pharmacist, as courses are given in most colleges in these branches; in this way the pharmacist becomes the co-worker of the physician in the diagnosis of the diseases of which mankind is affected.

Whether everyone will agree with all I have said or not, is it not better to give these matters attention? They mean much to both professions. As these and other infringements that often wedge in between these allied professions become adjusted we should have a better pharmacy and a better medicine, and together they will battle in the war on the ailments "that flesh is heir to." I can close in no better way than in the words of Dr. H. H. Rusby: "We are not taking part in this life for all that we can get out of it. The very best part is its voluntary sacrifices, the best part of our possessions, that part which we freely give away because it will do better work elsewhere than if retained in our own possession."

346 Montgomery Avenue.

THE NEW TEST FOR CANCER OF THE STOMACH, WITH SUGGESTED IMPROVEMENTS *

J. W. WEINSTEIN, M.D.
NEW YORK

I. INTRODUCTION

Medical means have been of no avail in the treatment of cancer. The only resort is surgery. If we succeed in radically extirpating the cancer *in toto*, the chances of a permanent cure are good. The importance of an early diagnosis in cancer in general, and in carcinoma ventriculi in particular, is obvious. Unfortunately in cancer of the stomach an early diagnosis is rather the exception than the rule, and in most cases, when we learn the diagnosis, we also learn the prognosis. The diagnosis of cancer of the stomach rests on the history of the patient; on the absence of free hydrochloric acid; on the presence of lactic acid, Boas-Oppler bacilli, a palpable tumor and occult blood; and on the occurrence of a variable degree of motor insufficiency. No single factor is diagnostic in itself, but a combination of these features is required for the establishment of the diagnosis. Unfortunately such a combination is not always present, and when it is present, it is not discernible at a very early stage of the disease. The Solomon test is of very little value. Any new sign that will aid in the diagnosis of carcinoma ventriculi is more than welcome.

A few months ago Neubauer and Fischer¹ published their results of a new test for the diagnosis of cancer of the stomach: the so-called glycylyltryptophan test. In order to comprehend the rationale of this test we must understand certain principles in physiologic chemistry. Our food, as such, cannot be assimilated by the system. In order to be absorbed most food substances must be converted into simpler cleavage products. Thus pro-

* From experiments conducted in the Laboratory of Biological Chemistry of Columbia University, at the College of Physicians and Surgeons, New York, under the auspices of the George Crocker Special Research Fund.

1. Neubauer and Fischer: *Deutsch. Arch. f. klin. Med.*, 1909, xcvii, 499.

teins to be absorbed by the system, must go through a series of changes, until they reach the simplest grade. This series of changes for coagulable proteins, such as albumin, is: (1) acid metaprotein, (2) primary proteoses, (3) secondary proteoses, (4) peptones, (5) "polypeptids" and finally (6) amino-acids. Amino-acids are the simplest cleavage products into which proteins must be broken up for assimilation by the body. The hydrolytic cleavage of the proteins into amino-acids is effected by the digestive enzymes. There are numerous amino-acids, such as glycine, alanine, leucine, tyrosine, tryptophan, etc., each exhibiting characteristic properties. In a normal stomach the digestion of proteins is never carried to the amino-acid stage. It is only in the intestines that extended hydrolysis into amino-acids occurs.

Various investigators have shown that cancerous tumors elaborate a certain enzyme which exhibits strong proteolytic powers, and which is capable of converting proteins as well as simple peptids into amino-acids. Although benign tumors, as well as other somatic tissues, possess similar properties, their peptid-cleaving powers are rather weak—they never equal the powerful peptidolytic action of malignant growths. Neubauer and Fischer have contrived to utilize this fact in a new test for cancer of the stomach. They used glycyltryptophan for this purpose.

Glycyltryptophan is a dipeptid,² one of the simplest types of peptids. As a synthetic product, it owes its existence to the ingenuity of Emil Fischer, who has made some of the most important chemical discoveries of modern times. Emil Fischer succeeded in combining various amino-acids into forms that closely resemble natural proteins of the simpler types. These synthetic peptids are like proteins in responding to the hydrolytic action of proteases³ and in yielding their corresponding component amino-acids. Glycyltryptophan, as its name signifies, consists of a union of glycine and tryptophan radicals.

In making their test, Neubauer and Fischer add filtered stomach contents to a solution of glycyltryptophan. The mixture is then placed in a thermostat for about twenty-four hours. At the end of that time a test is made for the presence of tryptophan. If tryptophan is found it means, according to Neubauer and Fischer, that an enzyme present in the stomach contents has converted glycyltryptophan into glycine and tryptophan. Such a result could not be due to normal constituents of stomach contents, e. g., pepsin, rennin, lipase or hydrochloric acid, since these agents do not, under gastric conditions, split either dipeptids or proteins into amino-acids. An enzyme capable of converting glycyltryptophan into glycine and tryptophan occurs in gastric contents only in cases of malignant growths of the stomach.

Glycyltryptophan was used for this test because tryptophan, which it easily yields, may be more readily detected than any other amino-acid. No protein yields a larger proportion of tryptophan. Tyrosine is perhaps the only other amino-acid which could be employed to similar advantage in such work. Tyrosine may be easily detected by reason of its comparative insolubility and its consequent tendency to crystallize. A dipeptid yielding a large proportion of tyrosine, such as glycyl-L-tyrosine might be expected, therefore, to serve as satisfactorily in this test as that particular dipeptid did in similar

work recently by Abderhalden⁴ in another connection. The simplicity, promptness and delicacy of the bromine test for tryptophan, however, give the advantage to the compound favored by Neubauer and Fischer. That the cleavage of dipeptid in the stomach in the case of cancer is done by an enzyme secreted by the tumor, and that it is not accomplished by pepsin, was shown by Kohlenberger.⁵

NEUBAUER AND FISCHER'S PRECISE METHOD OF PROCEDURE

In applying the glycyltryptophan test, an Ewald test breakfast is extracted in thirty to forty-five minutes after a meal and filtered. Glycyltryptophan⁶ is treated with some of the filtrate. The bottle containing the mixture is placed in a thermostat for twenty-four hours. At the expiration of that period the contents are tested for the presence of tryptophan. This is done as follows: About 3 or 4 c.c. of the contents of the bottle are removed with a pipette from underneath the layer of toluol and placed in a test-tube. A few drops of 3 per cent. acetic acid solution are added. Saturated aqueous solution or bromine is then added from a pipette, drop by drop, to the stomach contents in the test-tube, until a reddish violet color appears. The appearance of this color, at times a rose-red, shows the presence of tryptophan and the test is positive.

Considerable practice is required for the accurate performance of the test in the presence of very minute proportions of tryptophan, because slight excess of bromine may make the characteristic color disappear in a moment. Large excesses may impart a lemon-yellow color to the mixture. Whenever the reddish-violet color merges into yellow, we know positively that there is an excess of bromine in the mixture.

The opening at the tip of the pipette from which the bromine solution is dropped should be a fine one, and the "bromine water" added very cautiously, drop by drop, until, in case reaction is positive, a reddish-violet color appears. If reaction is very faint the test-tube should be left standing for a while. In about ten minutes, in such cases, the reaction may become considerably intensified. Usually 5 to 7 drops of bromine water are required to bring out the reaction in 3 to 4 c.c. of contents, but sometimes 1 to 2 drops are sufficient. When that is the case it is well to let a single drop of bromine water fall on the wall of the test-tube instead of into the liquid itself, in which case the volume of delivered bromine solution is reduced to a fraction of a drop, and excess is avoided.

Instead of bromine solution, pure bromine vapor may be used. If a bottle containing bromine is tilted slightly over the mouth of the test-tube, heavy bromine vapor will fall into the test-tube and dissolve in the liquid; and the reaction will promptly appear to its maximum degree. Great caution must be exercised, in this treatment also, not to add an excess of the vapor, for an excess will make the reaction disappear at once, and a lemon-yellow color may be imparted to the contents.

Bromine itself should be handled with great care, for it is extremely irritating to the respiratory mucous

4. Abderhalden: *Ztsch. f. physiol. Chem.*, 1909, xii, 136.

5. Kohlenberger: *Deutsch. Arch. f. klin. Med.*, xcix, 148.

6. Glycyltryptophan, as prepared for the test, is a clear watery solution. It is dispensed by Kalle & Co., Bleibach a. Rhein, all ready for use in little bottles. Each bottle contains a few minims of glycyltryptophan solution with a layer of toluol over it, as a preservative. This amount of glycyltryptophan is sufficient for one test. The bottle has a mark on it up to which the filtered stomach contents is to be added. The total capacity is about 15 c.c.

2. Dipeptid—a peptid containing only two amino-acid radicals.

3. Proteases are enzymes possessing the power of splitting up proteins or peptids, e. g., pepsin, trypsin, crepsin, etc.

membrane. Under no circumstances should plain liquid bromin be mixed with the gastric contents to be tested. An aqueous bromin solution may be kept saturated by retaining in it a slight excess of the heavy, liquid bromin.

Acetic acid is added to the mixture to be tested because the reaction appears only in an acid medium, perhaps very faintly so in a neutral one, but never in an alkaline medium. Almost all stomach contents are acid and in testing them for tryptophan the addition of acetic acid may not be necessary. In mixtures of very low acidity the addition of acetic acid seems to serve a useful purpose.

SPECIAL SOURCES OF ERROR IN THE GLYCYLTRYPTOPHAN TEST

Neubauer and Fischer made a series of tests in normal and pathologic cases and were extremely gratified by the results obtained. The following sources of error in the application of the glycytryptophan test are mentioned by them:

1. *Presence of Tryptophan in the Stomach Contents.*—Neubauer and Fischer advise tests for tryptophan in the stomach contents before glycytryptophan is added. If tryptophan is found, the specimen of stomach contents should be rejected, they say, and another one subjected to the test. I do not agree with Neubauer and Fischer in this regard, as I shall show further on in this paper.

2. *Presence of Peptid-Splitting Bacteria in the Stomach Contents.*—Neubauer and Fischer have tested the effects of pure cultures of various species of bacteria on glycytryptophan and have found that some species are able to split off tryptophan. The addition of toluol to the material in the test is proposed by them as a safeguard against such bacterial action. The passage of the stomach contents through a filter, according to them, also removes the offending micro-organisms. This danger is greatly overestimated by Neubauer and Fischer.

3. *Presence of Trypsin in the Stomach Contents.*—Duodenal contents may regurgitate into the stomach and the trypsin may split up the glycytryptophan. Neubauer and Fischer exclude this latter possibility by examining the stomach contents in gross for bile, which is easily recognized by its greenish color. In the presence of manifest bile another specimen must be used for the test.

4. *Presence of Blood in the Stomach Contents.*—According to Neubauer and Fischer blood is capable of splitting up glycytryptophan and thus serving as a source of error in the test. If the presence of blood is suspected, a test such as the guaiac or benzidin test should be made for it. If occult blood is present, Neubauer and Fischer recommend that that specimen be discarded and a new one tested. The danger from the presence of occult blood is also exaggerated by Neubauer and Fischer.

Lyle and Kober⁷ who recently reported the results of their study of this test as applied to twenty-one cases concluded as follows: "Our results with this test have been satisfactory. A repeated negative reaction is very valuable. When the test is positive, the complication of a regurgitation of trypsin must be thoroughly investigated."

2. METHOD OF EXPERIMENT

I have been engaged, during the past few months, in a study of the value of this new test for cancer of the stomach in its various aspects, and my experience agrees with the results obtained by the former investigators. I wish, however, to propose some important modifications based on a study of sixty-three normal and pathologic cases in all forms of gastric disease (see Section 4, Record of Cases).

It is my conviction that the employment of glycytryptophan is superfluous. The tryptophan reaction may be obtained without it. Every test of my series of cases was a double one (one with and one without glycytryptophan), and glycytryptophan was found to be unnecessary. The reason is obvious. The enzyme secreted by the cancer is potent enough to hydrolyze protein, as well as dipeptid into amino-acids; nor does it have to do it unaided, for in the vast majority of cases the associated pepsin converts accompanying protein to peptones. There were only about two or three instances in my series of cases, in which the test was positive in the presence of glycytryptophan, but negative in the absence of that compound. On the other hand, I had some cases in which the opposite was true—in which without glycytryptophan a better reaction was obtained than with it. More than that, I received the impression that the addition of glycytryptophan may at times serve as a source of error. It is possible that some of the bottled specimens of glycytryptophan undergo spontaneous decomposition into the component amino-acids. I noticed in two tests the production of a very deep red color in the presence of glycytryptophan, whereas in its absence no reaction occurred. (In one instance a clear-cut case of chronic gastritis. See Record of Cases, special Case 39.)

These observations aroused my suspicion. On one of the two occasions referred to, there was a surplus of the specimen of stomach contents under examination. I then tested that specimen with a sample of glycytryptophan from another bottle and obtained only the faintest trace of a reaction. There appears to be no other explanation for this exceptional result, than the assumption that the first sample of glycytryptophan contained free tryptophan.

I have subjected seventeen bottled samples of our supply of glycytryptophan to tests for free tryptophan. Distilled water instead of stomach contents was added to each of these bottles of glycytryptophan.⁸ The tests gave entirely negative results in each case. It should not be forgotten, however, that suspicion was aroused in only two out of nearly 150 instances, and, therefore, the seventeen negative results would not exclude the correctness of my assumption that two of the samples employed contained free tryptophan.

There are several advantages in excluding glycytryptophan from the test. Glycytryptophan is comparatively expensive.⁹ The toluolized samples form opaque, milky mixtures with stomach contents. Detection of slight proportions of tryptophan may be very difficult, often is impossible, in such opaque media. It is the clear solution only that develops, as a rule, a distinct and unmistakable reaction. Filtering the opaque mixture does not do any good in most cases. The opacity persists in spite of repeated filtrations.

8. Each bottle contained sufficient glycytryptophan for one gastric test.

9. Material for 150 tests, imported duty-free for use in this laboratory, cost \$50.

7. Lyle and Kober: New York Med. Jour., June 4, 1910, p. 1151.

Neubauer and Fischer advise the use of a regular Ewald test breakfast extracted in thirty to forty-five minutes. I found, however, that employment of a regular dinner and extraction of some of it at a later stage of digestion (within three or four hours), served the purpose better. I convinced myself of this in connection with specimens of contents from two cases that showed marked tryptophan reactions after a regular dinner, but failed to give any reaction after an Ewald test breakfast, the stomach having been washed previously (Cases 1 and 3). Both were obstruction cases. The Ewald test breakfast is ideal for testing the secretions of the stomach, but as an aid in the test for cancer enzymes, it is much inferior to a regular dinner. There is only one class of cases for which the Ewald test breakfast may be preferred. It happens occasionally, though very rarely, in cases of stagnation, that a stomach under the influence of a heavy meal will secrete hydrochloric acid, while the light Ewald test breakfast will not cause any secretion. It will be pointed out later that hydrochloric acid reduces the activity of, or may destroy, the cancer enzyme. When a negative tryptophan reaction is obtained in a case of pyloric stenosis showing free hydrochloric acid, it may be desirable to wash the stomach and administer an Ewald test breakfast, so that the contents may possibly be free from hydrochloric acid, and the elicitation of the tryptophan reaction favored on that account. (Group 11 illustrated this point.)

Neubauer and Fischer state that "hydrochloric acid, in a strength equal to 0.36 per cent., destroys this (cancer) enzyme." While the results of my experiments corroborate this general statement, there appear to be exceptions to it. Cases 11 and 16 gave marked tryptophan reactions in the presence of considerable free hydrochloric acid.

Neubauer and Fischer further advise the application of the tryptophan test to stomach contents before adding glycytryptophan for the detection of the cancer enzyme. If a positive tryptophan reaction is obtained with bromin water, that specimen, they say, should be discarded and a new one secured. But why discard it? This response tells the facts in the case! I detected preformed tryptophan in untreated stomach contents repeatedly. I obtained the reaction directly and easily. I have obtained it frequently in contents from cancer cases but in no others! Of course, if one intends to use glycytryptophan, the course prescribed by Neubauer and Fischer is the best one to pursue, but the results of my own research warrant the conclusion that the use of glycytryptophan for the detection of gastric cancer is superfluous.

I tried the effect of adding to stomach contents protein such as fibrin, or food from the meal, with the idea of enhancing the reaction, but the results were negative.

Neubauer and Fischer state that the tryptophan reaction must be obtained in twenty-four hours, or it is of no value, since bacteria are likely to hydrolyze the dipeptid and thus produce tryptophan. They experimented with pure cultures of micro-organisms and found that certain species possess proteolytic properties. As a safeguard against this contingency, as has already been stated, they advised the addition of toluol. My experiments have dealt not with pure cultures, but with stomach contents, as such. I have kept specimens of stomach contents over a month (some specimens being devoid of free hydrochloric acid), both with and without preservatives, and, except in carcinoma cases, tryptophan did

not develop from the admixed glycytryptophan. Only in two achylia cases, on very prolonged standing, did the reaction appear in contents from non-cancerous patients. Therefore, when an untreated specimen is kept for forty-eight hours in a thermostat, there is no special danger that bacterial development of tryptophan will occur. Sometimes a faint reaction becomes more marked in forty-eight hours. The addition of preservatives is superfluous and inconvenient. Thymol fragments form a heavy, milky emulsion with stomach contents, which is intensified by the addition of bromin water. Toluol is better, but it likewise forms a turbid mixture with stomach contents, and, as I mentioned before, such turbidity interferes with sharp elicitation of the tryptophan color reaction with bromin water. Chloroform and ether are best in this respect, but they seem to interfere somewhat with the reaction in certain cases.

I disagree with Neubauer and Fischer in their view that blood serves as a source of error in the glycytryptophan test. The testing of contents for occult blood is superfluous. I do not wish to be placed in the position of taking issue with Neubauer and Fischer on the proposition that blood contains proteolytic enzymes. My contention is merely that blood in stomach contents, in a quantity insufficient to be betrayed by its color, is not potent enough to hydrolyze protein or glycytryptophan into detectable quantities of tryptophan. This conclusion is sustained by observations in several cases, in which occult blood was present in the contents, as proved by blood tests, and yet no tryptophan could be detected after application of the glycytryptophan test. More than that. I even added blood to stomach contents by getting blood from the patient's finger, but no tryptophan could be obtained in the mixture even after standing in a thermostat for days. This was done by me on two patients, whose cases were both anacid. I also added blood from myself and from a fellow worker in the laboratory to glycytryptophan, in quantities just sufficient to impart a slight bloody tinge to the solutions, but after six days' incubation in a thermostat none of the mixtures contained a trace of tryptophan. Of course, it is probable that if a large quantity of blood is added to gastric contents, tryptophan will be formed, but such contents are, in general, worthless in this connection for another reason, namely, that it is impossible to discern the characteristic tryptophan-bromin color in a red or dark-colored medium. Occult blood, therefore, cannot serve as a source of error in the tryptophan test.

Duodenal contents which have regurgitated into the stomach are likely, if sufficient in quantity, to vitiate the test, since the contained trypsin may convert proteins into amino-acids and thus produce tryptophan that might be ascribed to cancer enzyme. Unless bile is manifestly present in the gastric contents, however, there is little or no danger in this connection, assuming, of course, that bile and pancreatic fluid always appear together. Neubauer and Fischer aptly remarked that no chemical test need be made for bile in doubtful cases. It is sufficient, they believe, to examine the contents in gross and if bile is obviously present, as evidenced by greenish color of the contents, such a specimen should be discarded and a fresh one obtained. Occult bile could hardly be accompanied by sufficient trypsin to produce a detectable amount of tryptophan in the test.

Lyle and Kober seem to be impressed by the possible influence of the trypsin that may occur in stomach contents in this relation. From extended experience in stomach work I can say that duodenal material rarely

appears in stomach contents. Duodenal fluid may occasionally be present in very trivial amounts, but it cannot then vitiate the tryptophan test. Moreover, pepsin in the presence of acid destroys trypsin. Acid itself does so. To serve as a source of error in the tryptophan test, duodenal contents must be present in large quantities, and the stomach contents must be alkaline. These two conditions prevail only when there is an obstruction of the duodenum below the papilla and in certain pathologic cases following gastro-enterostomy, in which the drainage goes from the afferent loop into the stomach, instead of into the efferent loop. I have had several such cases; two of them are included in these experiments (Cases 14 and 15). But in cases like these the presence of duodenal contents may be determined without any difficulty.

After all is said, one fact stands out prominently, viz., that the glycytryptophan test yields positive results in practically all cancer cases and hardly ever in any others, as may be seen from the reported results of the experiments by Neubauer and Fischer, Lyle and Kober and myself.

THE AUTHOR'S TRYPTOPHAN TEST

The test, as I have modified it and now recommend it, is made as follows: Four or five hours after a regular dinner, some stomach contents are secured, filtered and tested with bromin water for tryptophan. If present, reaction is positive. If absent, some of the filtrate transferred to a stoppered bottle and treated with a little toluol, or better still, without a preservative, is put in the thermostat and tested again for tryptophan twenty-four to forty-eight hours later. Although the reaction very often develops at room temperature, the mixture should be kept in a thermostat for the period stated.

DEFICIENCIES OF THE TRYPTOPHAN TEST

The most serious defect of the tryptophan test is its inconstancy. The reaction may be present in one specimen of stomach contents and absent in another from the same patient. The only safeguard against this uncertainty is, in case of negative results, to test three or four specimens obtained at different times. If three or four tests yield negative results, the case is most likely non-cancerous. Work now in progress may ultimately indicate the reasons for the inconstancy referred to. (See addendum.)

Satisfactory results are unattainable unless the contents are practically colorless. Admixture of coloring matter may make it impossible to conduct the test. The presence, therefore, of blood or coffee-grounds in the contents makes it necessary to select another specimen for the test. In giving the patient a meal for the test, he should be instructed not to ingest any foodstuffs that are likely to impart color to the contents. Coffee, tomatoes, strawberries, etc., for obvious reasons, should be excluded. Tea must not be strong, else the contents will be sufficiently reddish to render the test useless. (See addendum.)

The fact that free hydrochloric acid interferes with the activity of the cancer enzyme or may destroy it altogether, is a serious obstacle in the way of reliable employment of the tryptophan test.

3. GENERAL CONCLUSIONS

A critical review of the results obtained in this study of the tryptophan test convinces me that it is a valuable sign in the diagnosis of cancer of the stomach. It is a

sign in itself. The other signs of cancer, such as absence of free hydrochloric acid and presence of lactic acid, occult blood, coffee-grounds, etc., have no value whatever, when taken individually, since they appear in conditions other than carcinoma. They are of value only in conjunction with other data. Moreover, none of these has any negative value. In these respects the tryptophan test is superior to any of them. True, it is inconstant, but are positive results from the Widal test, the finding of the tubercle bacilli, the finding of plasmodia, constant features? However, in matters of such importance many observations must be made before conclusive deductions can be drawn. I cheerfully recommend this simple tryptophan test to the profession for the further study and more complete determination of its real value.

Is it an *early* sign of cancer? I do not know! I have not been fortunate enough, as yet, to get a very early case and determine the matter, one way or the other. Much more work must be done in this connection before that important question can be answered.

I wish, in this connection, to express my indebtedness to Prof. William J. Gies of the College of Physicians and Surgeons, who has placed his laboratories at my disposal and has secured the support necessary for the conduct of this rather expensive research. With his ever-ready counsel and valuable suggestions he has contributed greatly to the success of my work. I also express my indebtedness to Prof. Francis Carter Wood of St. Luke's Hospital, Miss Selma Granat of the Presbyterian Hospital, Dr. Julius Rudisch of the Mount Sinai Hospital and Drs. A. Zemansky and W. Weinberger of the Lebanon Hospital for supplying stomach contents of some very interesting cases.

ADDENDUM

In an endeavor to perfect my methods further, while the manuscript of this paper was in the hands of the editor, I made observations warranting the following preliminary conclusions: Pepper interferes with the tryptophan-bromin reaction; so does lemon juice. Sugar is an excellent stimulant to the secretion of cancer enzyme; beef is much better than chicken. A good meal for the tryptophan test is one consisting of bread and butter, with meat prepared very plainly without extra seasoning or dressing, and some very sweet, weak tea. I made about a dozen tryptophan tests recently on each of two patients (Cases 16 and 17), and, using such meals, obtained uniformly positive results in almost every test.

I have secured excellent results by giving a meal consisting of white bread and very sweet weak tea without milk, the meal having been extracted in one hour. This statement is based, however, on tests on only two patients.

4. RECORD OF CASES

1. CASES WITH CONTENTS YIELDING A POSITIVE TRYPTOPHAN REACTION *

CASE 1.—M. G., male, aged 49. Free hydrochloric acid, 0; total acidity, 58. Lactic acid, present. Two tests were made for tryptophan; both were positive. Tryptophan was present in the gastric contents immediately after removal from the stomach. A test breakfast, after lavage of the stomach, failed to yield contents giving the tryptophan reaction even after standing several days in the thermostat. The patient

* Every test referred to in this record as a tryptophan test, unless otherwise indicated, was a double one—with glycytryptophan and without it. The results in each case were identical in quality unless otherwise indicated.

was operated on and proved to have an extensive carcinoma originating in the pylorus.

CASE 2.—I. S., male, aged 45. Clear-cut carcinoma. Coffee-grounds. Free hydrochloric acid, 0; total acidity, 136 to 166. Lactic acid, considerable. Immediately after removal of contents from the stomach a faint tryptophan reaction was directly obtained. After forty-eight hours in the thermostat, this reaction was more marked.

CASE 3.—S. D., male, aged 61. Clear-cut carcinoma involving the pylorus. Marked peristaltic movements. Free hydrochloric acid, 0; total acidity, 6. Lactic acid, considerable. Two tests were made for tryptophan; both were positive.

CASE 4.—G. E., male, aged 54. Cancer involving the pylorus. Three tryptophan tests were made, with two positive results and one negative. Free hydrochloric acid, 0 to 34; total acidity, 42 to 66. No lactic acid.

CASE 5.—G. E., male. Autopsy: cancer of the pylorus. Five tryptophan tests were made, two with stomach washings. Three Ewald test breakfasts were given. One Ewald tryptophan test was negative; the others were positive. In two tests the direct tryptophan reaction appeared after forty-eight hours' standing in a thermostat, but not before.

CASE 6.—N. T., female, aged 46. Palpable tumor. Patient died. Clear-cut carcinoma. No free hydrochloric acid in stomach contents. Two tryptophan tests were made with positive results. In one test the reaction was slight.

CASE 7.—S. F., male, aged 73. Cancer of the pylorus. Marked stasis of food. Free hydrochloric acid varied in quantity from a trace to 24; total acidity, 88. Lactic acid, present. Four tryptophan tests were made. Two were positive and two negative. The contents that gave the negative result contained free hydrochloric acid, 24.

CASE 8.—D. P., female. Cancer of the pylorus and posterior wall. Operation. A test for tryptophan was positive.

CASE 9.—S. N., male, aged 28. Carcinoma of the lesser curvature. Operation. Free hydrochloric acid, 0; total acidity, 6 to 14. Lactic acid, present. Two tryptophan tests were made; one was positive, one was negative.

CASE 10.—G. H., male, aged 51. Carcinoma ventriculi. Free hydrochloric acid, 0; total acidity, 10. Lactic acid, present. Palpable tumor. A tryptophan test was positive.

CASE 11.—S. D., male, aged 52. Carcinoma ventriculi. Marked peristaltic movements. Dilated stomach. Marked stasis. Refuses operation. Free hydrochloric acid, 26; total acidity, 92. Lactic acid, present. A specimen of stomach contents with the above acidities showed a marked direct tryptophan reaction. On two other occasions, with acidities of free hydrochloric acid, 50 to 72; combined, 24, and total, 108 to 130, direct tryptophan reactions were positive. One month prior to this, two tryptophan tests were negative.

CASE 12.—C. C., female. Suspected carcinoma. Two tryptophan tests; one positive, one negative.

CASE 13.—A. S., male, aged 36. Free hydrochloric acid, 32; total acidity, 76. This did not appear to be a cancer case. Unfortunately the patient could not be kept under observation. One tryptophan test was made with a positive result.

CASE 14.—A. T., female, aged 33. Material from the stomach contained much bile on repeated examinations. Free hydrochloric acid, 0; total acidity, 20. The patient underwent a gastro-enterostomy for pyloric ulcer two years ago. Non-cancerous case. Two tryptophan tests were made; both positive.

CASE 15.—S. G., male, aged 52. Jejunal ulcer. Gastro-enterostomy four years ago. Non-cancerous. Material from the stomach contained much bile on repeated examinations. Free hydrochloric acid, 0 to 28; total acidity, 24 to 68. One positive tryptophan test was made.

CASE 16.—R. K., male, aged 54. Case of suspected carcinoma. Free hydrochloric acid as high as 50; always present. About a dozen tryptophan tests were made and almost all were positive.

CASE 17.—I. C., male, aged 46. Clear-cut case of cancer. Palpable tumor. Cachexia. Coffee grounds. Very poor motility. Free hydrochloric acid, 0; total acidity, 14. Lactic acid, considerable. A dozen tests for tryptophan were made; all were positive.

CASE 18.—L. B., male, aged 65. Patient of Dr. Jerome M. Lynch. Clinical diagnosis by Dr. Lynch, carcinoma ventriculi. Operation by Dr. Lynch about 2½ years ago for cancer of the rectum. Free hydrochloric acid, 0; total acidity, 14. Lactic acid, trace. Starch digestion, good. Occult blood, present. One test for tryptophan was made with a positive result.

CASE 19.—Mrs. M., aged 54. Patient of Dr. William Weinberger. Undoubted case of carcinoma. Operation revealed a tumor in the pyloric region. Free hydrochloric acid, absent. Lactic acid, present. Two tests were made for tryptophan by Dr. Weinberger. The first was negative; the second, positive.

II. CASES WITHOUT FREE HYDROCHLORIC ACID IN THE STOMACH CONTENTS AND NOT YIELDING POSITIVE TRYPTOPHAN REACTION

CASE 20.—S. L., male. Suspected carcinoma. Free hydrochloric acid, 0; total acidity, 48. Lactic acid, negative. One test was made for tryptophan, but with a negative result.

CASE 21.—J. O'H., male, aged 41. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 44-76. Lactic acid, 0. Two tryptophan tests were made; both were negative.

CASE 22.—A. C., female, aged 38. Suspected carcinoma. Free hydrochloric acid, 10; total acidity, 34. Lactic acid, 0. Blood in contents. Two tests were made for tryptophan; both were negative.

CASE 23.—C. R., female. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 14. Lactic acid, 0. Several tryptophan tests were made; all were negative.

CASE 24.—A. N., female, aged 55. Achylia gastrica. The patient has been under my observation for the past nine years. Several examinations were made for tryptophan; all were negative. Free hydrochloric acid, 0; total acidity, 6. Lactic acid, 0.

CASE 25.—A. N., male. Achylia gastrica. Free hydrochloric acid, 0; total acidity, 8. Lactic acid, 0. One tryptophan test was made with a negative result.

CASE 26.—R. H., aged 52. Spasmodic stricture of the upper part of the esophagus. Free hydrochloric acid, trace; total acidity, 36. Several tryptophan tests were made, but all were negative.

CASE 27.—I. D., male. Chronic gastritis (alcoholic). Free hydrochloric acid, 0; total acidity, 14. Lactic acid, 0. One tryptophan test was made with a negative result.

CASE 28.—N. F., male. Suspected carcinoma. Free hydrochloric acid, 0; total acidity, 16. Lactic acid, 0. One tryptophan test was made with a negative outcome.

CASE 29.—R. McM., female, aged 42. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 38. Lactic acid, 0. Three tests were made for tryptophan; all were negative.

CASE 30.—A. M. K., aged 36. Gastroparesis, hypoaecidity. Free hydrochloric acid, trace; total acidity, 24. Lactic acid, 0. Two tryptophan tests were made; both were negative.

CASE 31.—O. D., female. Diagnosis; achylia gastrica. Free hydrochloric acid, 0; total acidity, 4.

CASE 32.—E. T., female. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 40.

CASE 33.—B. J., male. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 25.

CASE 34.—D. F., female. Diagnosis, achylia gastrica. Free hydrochloric acid, 0; total acidity, 6.

CASE 35.—B. S., male. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 20.

CASE 36.—D. P., female. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 32.

CASE 37.—L. L., male. Chronic gastritis. Free hydrochloric acid, 0; total acidity, 16. Lactic acid, 0.

CASE 38.—M. B., female. Achylia gastrica. Free hydrochloric acid, 0; total acidity, 8.

III. SPECIAL CASE, YIELDING TRYPTOPHAN REACTION WITH GLYCYLTRYPTOPHAN, BUT NONE WITHOUT IT

CASE 39.—B. C., male. Chronic gastritis and hyperacidity, very marked tryptophan reaction with glycyltryptophan; none without it.

† At least one test with glycyltryptophan and one without it was made in each of Cases 31-38, with uniformly negative results.

IV. CASES. NOT YIELDING TRYPTOPHAN REACTION

None of the cases in this group gave the tryptophan reaction. The tryptophan test was repeated several times in many cases. The gastric contents from all these cases had free hydrochloric acid.

Six cases of hyperacidity.

Three cases of chronic gastric ulcer.

Five cases of neurasthenia.

One case of contraction of gastro-enterostomic orifice four years after operation. Marked stasis of food. Dilated stomach.

One case of arteriosclerosis.

One case of hypernephroma. Patient died.

Three cases of gastric atony, with marked stasis of food.

Two cases of gastropnoia.

One case of enlarged gall-bladder, probably due to calculi.

One case of chronic constipation.

71 East Ninety-sixth Street.

A STUDY OF THE BACTERIAL FLORA OF
THE NASAL MUCOSA IN THE
PRESENCE OF RHINITIS*

WILL WALTER, M.D.
CHICAGO

This study represents an effort, extending over about two years, to learn something of the bacterial flora of the upper respiratory tract in the presence of disease. The purpose was to ascertain, first, whether the flora in our territory are comparable to regions where such investigations have been made, namely, in various parts of England and in Germany; secondly, to uncover, if possible, the etiologic factors in infections of the mucosa of this tract. Most of these infections are more serious in their final results than they are usually considered. They may not only be the precursors of diseased adnexa, of cervical adenitis, often of meningitis, but, by the absorption of formed toxins, they are worthy of consideration for the part played in hemic and vascular disorders leading to arterial hypertension and its sequelae.

These are, fundamentally, infections which are peculiar to the mucous surfaces and, of course, must vary according to the environment, habits and social status of the infected subjects.

Only infections of the nasal mucosa are reported here. Detailed reports on specific bacteria will cover the other regions.

CHARACTER OF THE RESEARCH

In this study endogenous diseases are not considered, only ectogenous bacterial invasion. The whole study includes examinations of about 250 cases of diseases of the upper respiratory tract, including a number of ear infections which presuppose postnasal infection, a considerable number of tracheal infections and a limited number from the polybacterial pharynx. Out of this research are taken 100 cases of nasal infection, listed in order of record, and these include a few cases of pernasal secretion from sinusitis.¹

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. I must acknowledge my great obligation to the following individuals: Aaron Arkin, who carried through the cultures of the first series of sixty-four cases in the bacterial laboratory of the University of Chicago through the courtesy of Professor Jordan; Dr. Mary C. Lincoln, who carried through the second series of fifty cases and has critically examined the whole list; and my assistant, Miss Copeland, who with me has worked out the third series of 136 cases. I am also indebted to men in the laboratory of Wright and confirmation of my findings in the probably most frequent causal factor—the *Bacillus segmentosus* of Cautley—and for courtesies extended by them. Without the cooperation of all these people it would not have been possible to carry out so thoroughly such a number of examinations in the time of the research.

The whole series represents a greater number of diseases than of individuals, and this discrepancy between diseases and persons infected is due to a fact to which I shall later call attention more specifically, namely, the fact that it is not unusual to find coincident infection on different areas of the upper respiratory tract caused by distinct bacteria on the respective areas involved. The fact that bacteria grow with varying degrees of rapidity and virulence is, of course, well known, but it becomes a matter of importance, (from the therapeutic side), to appreciate the possibility of this contemporaneous infection of different regions.

This locally variable susceptibility is probably due to three conditions: (1) the variation in culture media offered by the locality; (2) the variation in virulence in the respective regions, depending, doubtless, on specific local resistance to invasion; (3) the lowering of bacteriostatic pressure in reflexly related regions through stasis, the evolution of disease in one locality producing the lowered resistance in a region closely associated with it. As to regional variation, we know the proclivity for multiplication of the gonococcus on the mucosa of the urethra and of the conjunctiva, but it is rarely found growing on the upper respiratory tract. On the other hand, the pneumococcus has an adaptive habit which enables it to grow fairly well on the conjunctiva, well in the nose, ear and pharynx, and luxuriantly on the pulmonary mucosa, and even on the bloodstream itself; but it is not equally virulent in all sites *in vivo*, and is most selective as to its growth *in vitro*. So, as will be seen from the findings, the bacteria vary greatly in their selection of surface on which to grow.

METHODS OF THE RESEARCH

Film preparations were made from the secretions taken by platinum loop, if plentiful, or by sterile swabs, if scant, and fixed in flame. For cultures a platinum loop sterilized in flame was introduced directly on the area involved in the inflammatory reaction. This method was used for all inoculations and, acting on the advice of the English workers in this field, they were made on Loeffler's blood-serum mixture which, as will be seen later, is probably not altogether reliable in fulfilling the possibilities of development for many of the organisms. They were all stained by Gram's method. In the presence of diverse colonies, subcultures were made and, from pure cultures obtained, cultural tests were carried out.

The method of obtaining materials differs from that employed by some of the English and German investigators and is more reliable, since some of them have depended on secretion blown from the nostrils, which is almost certain to be contaminated by the ever-present cocci in the skin and hairs of the interior nares, and unless special care is taken, mixes the secretions from the two nares. If the secretion is abundant, it is, of course, possible to wash the larger masses thoroughly and to obtain from them uncontaminated material, but in the beginning of acute infections, when there is only watery secretion, it is difficult to get such masses.

The method of blowing the material from both nostrils would be inaccurate in many cases, for there is abundant evidence that the two sides of the noses may vary as to their bacterial content, particularly in early stages of infection. It is even possible to have acute rhinitis on both sides caused by distinct organisms. In one case there was an acute febrile attack starting on the left side of the throat, passing to the left nostril and

into the left frontal and, possibly, anterior ethmoidal cells, with the coincident development of frontal sinusitis on the right side, but with a different organism present. In this instance, it seemed that the bacterial infection on the left side did not pass to the right side at all, but so lowered the resistance through reflex vascular stasis that a latent infection became manifest on the right side. I judge this from the accidental fact that we had made a culture from the right frontal sinus a few weeks previously, which was also predominant in this finding. In this case our technic proved valuable and the evidence was incontrovertible, presenting the interesting feature of a patient suffering constitutional symptoms from pneumococcus infection on the left side and the local pressure symptoms from a staphylococcus on the right side. Instances might be multiplied, showing the fallibility of diagnosing the infection from specimens from areas other than those involved in inflammatory reaction, and justifying the technic employed. Coincident infection of the trachea by *Micrococcus catarrhalis* with rhinopharyngeal infection showing Cautley's bacillus, has been observed several times.

TABULATION OF FINDINGS

Table 1 represents the 100 cases of nasal infection. The acute on chronic and acute on subacute are considered as acute infections, but they will also show among the subacute and chronic cases of rhinitis though counted but once. The number of acute cases are therefore sixty-four. There are thirty-four subacute and eleven chronic; five cases of acute sinusitis and nine cases of chronic sinusitis.

This table presents some interesting and instructive features. The number of cases and specimens examined is greater than the combined reports of the English observers, and differs in results from some and, in percentages, from all. Many bacteria are present accidentally and not in a casual way.

In Table 2 the bacteria are arranged by groups taken in the order of percentage of finding.

The Staphylococcus Group

The three varieties of staphylococcus, *S. albus*, *S. citreus* and *S. aureus*, are listed separately, making a total of fifty-six cases, indicating a presence of these pus cocci in 56 per cent. of all cases of infection studied; other cocci added bring the total to 73 per cent. Lewis and Turner² made a study of twenty-six specimens from normal noses, disclosing pus cocci in 50 per cent.; but the most notable extended studies are those by Hesslauer³ covering 186 specimens from the normal in which staphylococci are present in 25 per cent., and by Neumann⁴ covering 206 cases, which showed the presence of *S. albus* in 98 per cent., *S. aureus* in 30 per cent. and *S. citreus* in 12 per cent.

Our percentage of staphylococci in infected cases is probably relatively very high. In some of these cases they seem to be the only organism present. The evidence of German and English observers is, however, against the probability of primary infection by them; they are almost universally considered as secondary invaders. Workers in the field of the conjunctiva have found it very difficult to grow staphylococci on the conjunctiva, while as to the study of staphylococcus infection in otitis there seems to be a great lack of agree-

4. Ztschr. f. Hyg., 1902, xl, 33.

ment, such men as Pes and Gradenigo⁸ maintaining that they are always secondary invaders, while Zaufal and Roskin⁹ feel that they may replace the primary exciting bacteria and a few assert that primary infection by staphylococci is possible.

It would seem that time must be allowed for the better differentiation of this group. While in some of these cases they seem to be the only possible causal organism, such a case as 74, pneumococcus infection, might easily have been laid at the door of staphylococcus, since staphylococci were present on the first day of the attack, no pneumococci being recovered from the secretion. At the end of a week, during which time the boy was not seen and had been very ill with typical pneumonia rhinitis, the smears and cultures showed pure culture of pneumococci. A few days later, staphylococci again appeared in the secretions and the pneumococcus disappeared.

Several cases showing pure culture of staphylococci in very red pharynges, and a few ear cases, in which the staphylococci were the only demonstrable agents in the attack, have been observed. It is only lately that we have been testing the liquefying reaction of the staphylococci and, in all cases observed in this regard, we have

the cases in which they are present alone, that is, twenty-four times. Probably in these cases they are secondary to irritation other than bacterial, and possibly many would prove like Case 74, should repeated examinations be made. We are not considering the frequently occurring furuncles in the nasal vestibule. These are indisputably due to staphylococci and usually—possibly always—the aurens.

The Diphtheria Group—*Bacillus Segmentosus* of Cautley

The second in percentage order of occurrence 35 per cent., the *Bacillus segmentosus*, is worthy of special consideration, but time is not available for it. A detailed description of this interesting organism will follow.

Though discovered by Cautley,⁸ working under the local government board of London, in 1893, and investigated since by Gordon,⁹ by Prosser-White,¹⁰ by Benham¹¹ and by Allen,¹² and commonly known in England under the name of *Bacillus septus*, it is almost unknown in our literature. I had noted its presence for several years and had it reported by laboratories as “diphtheroids,” “Gram-positive diplococci,” etc., but

* Based on conclusions of literature and my own clinical and bacteriologic observations.
† Named from color of growth on blood-serum; classified by morphology.

found the liquefiers to be associated with the more acute inflammatory reaction. This is in accord with the final conclusions of Axenfeld⁷ and others who have studied this group, namely, that the liquefying staphylococci are the virulent ones and that most of the others are harmless.

If staphylococci invade the mucosa in a secondary way, it would seem that they do so because the primary infectors produce local injury to the mucosa, in like manner that staphylococci invade the skin following local irritation and lowering of resistance. In that event it is pertinent to inquire why they may not cause rhinitis, if present on the mucosa when it is injured by foreign matter, or by chemical or thermal irritation. If that they are mostly of secondary occurrence they may be secondary to other irritants when they could not be said to occur in themselves. Such a case would be atypical clinically. Such the case.

However, of this great preponderance of primary invasion, we can not conclude factors in starting the inflammation. I call them “possibly causal” in

could not identify it positively; I failed to ascertain anything of it from bacteriologists in this country and did not appreciate what I had, until Allen described it in 1908. On a visit to London last year I submitted my slides to Allen and to men in the Wright and Douglas laboratory, who confirmed the finding. So what I here report is known through England as the *Bacillus septus* (Cautley’s bacillus).

It is a diphtheroid, Gram-positive bacillus, club-shaped, with rounded ends 0.2 or 0.3 by 0.5 microns. Its chief morphologic characteristic is the segmentation or barring due to an unstained septum, which caused Cautley to give it the name of *Bacillus coryzae segmentosus*—coryza because he thought it to be the cause of the coryza of epidemic influenza.

Prosser-White found it in all of seven cases, Benham in twenty-five of twenty-seven and Allen in eleven of forty-two cases of acute rhinitis. It was not alone in these cases, but apparently predominant and was thought causal. My percentage is not so high as Cautley’s, Prosser-White’s or Benham’s, but it is higher than Allen’s, and this, as will be brought out in a later specific report

on the organism, may be accounted for by the fact that all but Allen's studies were taken from epidemic periods. Allen's was part of a research covering four years, and mine, a greater number of cases than all of the others combined, also covered a longer period and may thus be inclusive of epidemics. Attention is also called to the fact that Benham's 90 per cent. occurred in the months of November and December and in mine, if the occurrence in autumn months were taken out, a high percentage would be obtained, that is, in epidemic form. It is also interesting to note that, during the past two months (spring), we have not obtained from any of the many cultures in acute rhinitis a single specimen of *B. segmentosus*, though we have tried every case for it in hopes of showing a fresh culture for inspection. It seems from these facts that possibly this bacillus is epidemic in the autumn months.

The addition to this list of twenty-five or thirty new cases, worked out since this report was closed, would alter the percentages, adding materially to the next-mentioned organism, *Micrococcus catarrhalis*, fifteen or twenty, and to a new tiny diplococcus, Gram-negative and so far unclassified, eight or ten cases, thus reducing the preponderance of *B. segmentosus*.

The evidence is much in favor of the *Bacillus segmentosus* as a primarily etiologic organism in rhinitis. As to its being a distinct bacteriologic organism, however, there is some doubt, since its margin of differentiation¹³ from the *Bacillus xerosis* and the *Bacillus septatus* of Gelpke,¹⁴ both of which are innocuous to the conjunctiva, is small and both may be identical therewith. From secretions it is a slow grower, sometimes appearing only after three days; it does not liquefy gelatin and it grows in discrete colonies with serrated edges. In subcultures it grows more rapidly and coalesces.

Clinically it is quite characteristic, starting nearly always in the throat after a few hours' incubation, and passing to the nose. It has been recovered five times from the ear in twenty-six cases of acute otitis; it was found in one case of sinusitis and has persisted for over a year with *Mucosus capsulatus*—seventeen cases examined—and was obtained three times from cough cultures; so that it may be said to have a strong predilection for the nasal mucosa, where it develops an acute reaction, typical rhinitis, with little or no tendency to chronicity. Counting out the cocci and other organisms known not to be causal in coryza, it may be said to be the only causal organism present in 19 per cent. of cases examined, occurring also eleven times with *Micrococcus catarrhalis* and five times with other possible causal bacteria.

The other diphtheroids are few numerically, but some of them are severe in their manifestations; one, Case 78, not reported in this list, in which was found the yellow bacillus like that in Cases 79, 92, 100 and 104, all severe, produced the most nearly fatal rhinitis and otitis I have seen, with temperature range from 106 to 96. This case I intend to report specifically.

Micrococcus Catarrhalis

This Gram-negative coccus is misnamed, because it is wrong to convey such an impression of mild and benign character as is given by such a name. In some ways it seems the most dangerously infectious of all the bacteria, because of its prevalence, its capacity for wide-spread growth on the mucosa, its recently proved ability to cause

meningitis, its clearly infectious character and the frequently caused painless otitis media caused by it.

It is noted in 20 per cent. of rhinitis and may be considered as alone causal in 8 per cent. Noted epidemiologically since the closing of this report, that is, in the months of April and May just passed, this percentage would be about 60 and the addition of these last cases to our list of 100 would increase its presence alone from 8 per cent. to 18 per cent. In the whole research its presence is noted in thirteen cases of throat and trachea and seven cases of suppurative otitis. In symbiosis with the *Bacillus segmentosus* there seems to be an exaltation of virulence.

When found in otitis media suppurativa in pure culture it has produced less pain and has undergone resolution following paracentesis more quickly than any other infection that has come to my notice. In the ear it is quite likely to abort.

There is not much in the literature on the subject of this organism. We have been able to differentiate several strains of quite characteristic action and reaction, but into that I am not prepared to enter at this time. Attention may be called in passing to its morphologic and, in some strains, culture similarity to the meningococcus on one side and the gonococcus on the other.

I believe that there has been an epidemic of *Micrococcus catarrhalis* infection in Chicago this winter and spring. In the winter epidemic and in tracheal infection generally it seems most persistent, but in this spring's epidemic (not reported here) it has been mild and self-limited. Some of the series we have encountered since this report culture differently and may prove to be another organism of the same group.

Lastly, attention is again called to its recovery post mortem from an increasing number of cases of meningitis and to the fact that its proneness to cause slight subjective disturbance may account for many an obscure case of meningitis of nasal or aural genesis.

Bacillus Mucosus Capsulatus (Friedlander's *Pneumobacillus*)

It has been a matter of surprise to note almost complete absence of this organism in acute infections, because I was prejudiced in favor of its finding in the beginning of the study. None of the observers whom I have quoted, however, with the exception of Allen, have found it in the epidemic investigated. If I had not spent some time in Allen's laboratory and become familiar with his method of working, and if I did not know his thoroughness as a bacteriologist, I would doubt the possibility of its causing acute rhinitis, since we have found it present so rarely and then, with two possible exceptions, confined to chronic cases. Allen reports Friedlander in thirteen of his forty-two cases, but by his table it may be considered as alone causal of acute rhinitis only in six cases, or 14 per cent., as against Von Besser's¹⁵ 2.5 per cent. and Lewis and Turner² 4 per cent. for normal noses.

Attention is called to the fact that authorities have come to consider the *ozena bacillus*¹⁶ of Lowenberg and Abel¹⁷ as identical¹⁸ with the *pneumobacillus* of Friedlander, since they are alike morphologically, in staining reaction, and in nearly all of their cultural peculiarities as well as their pathogenicity for animals. In four of my cases the diagnosis of *ozena* would properly be made;

two of them were seen by other men and were so diagnosed. I reported it as possibly causal in two acute cases.

Pneumococcus—Fraenkel

None of the articles quoted in this report mention the finding of the pneumococcus in acute rhinitis, which seems rather remarkable, particularly for Allen's research, which covered four years and would, one would imagine, report some findings. Hesslauer³ gives the enormous percentage of 49.7 and R. O. Neumann⁴ 22 per cent. for abnormal noses, but neither states what sort of cases he reports. It is certainly a very frequent cause of acute infection in this climate. Pneumococcus infection in the eye is quite common and it acts like my reported Case 137, in that as soon as the pneumococcus disappears the staphylococci become more obvious, appearing in large numbers.

Patients with this infection are severely ill. These cases constitute many of those which are diagnosed as grip. Especially is it noteworthy, though I have not seen it mentioned anywhere, that these infections frequently terminate by crisis. I believe that Axenfeld noted it in relation to pneumococcus eye infections, but the reference is mislaid.

Several instances have been observed in which typical pneumonia temperature range was exhibited without, so far as could be ascertained, any pulmonary involvement. This is an intensely interesting observation and is recommended for consideration.

Attention is also called to the fact that, in all cases in which pneumococcus is present, it is in pure culture, barring a notation I have already made, that staphylococci precede and follow its activity. These observations have raised many interesting points that may not be entered into at this time.

Bacillus Pyocyaneus

I have seen no mention of pyocyaneus in relation to nasal infection. It must be very rare, and English confrères with whom I talked are of the opinion that it probably grows in structures deeper than the mucous membrane.

Morax-Axenfeld and Koch-Weeks Bacilli

Morax-Axenfeld and Koch-Weeks bacilli have been very commonly observed by others, but I have seen them only the three times mentioned.

Influenza "Beta" Bacillus

The influenza "beta" bacillus presents many points of interest. I call it influenza "beta" because it is not the influenza bacillus, but belongs to this group. It should have more extended study.

The other organisms are probably of accidental occurrence and not worthy of note.

Influenza Bacillus—Possibility of Failure

It is especially interesting to call attention to the fact that in 250 cases examined the influenza bacillus has not been encountered once, nor was it noted by any of the English observers whose reports go back several years, except in an epidemic on the Riviera, in which the pneumococcus is reported as causal with *B. influenzae*, *M. catarrhalis* and *paratetrigenus*. This is surprising in view of the fact that diagnosis of grip colds have been made daily from clinical manifestations by physicians and specialists all over the country these years.

I report in this series four specimens in which no growth occurred and from whose smears no diagnosis could be made. This reveals the fact of the possibility of error in this research to which I previously called attention, namely, the fact that all cultures were made on Loeffler's blood-serum mixture.

It is pretty generally understood among experts on the subject that the influenza organism grows poorly on blood-serum unless some hemoglobin be present and, although there have been no cases which could clinically be adjudged influenza, it is possible that, had we used hemoglobin containing media for the influenza group (so-called hemophile pole bacteria) which grow with certainty only on them, we should be more certain as to the occurrence of influenza.

In like manner errors may have occurred with relation to the pneumococcus, although it is much more easily recovered from smears, had we used some such formula as that of Wertheim, on which organisms such as gonococcus and pneumococcus and Koch-Weeks bacillus grow best. It is also possible that better results might be obtained for the *Micrococcus catarrhalis* with the so-called nasgar mixture recommended by Wasserman.

These various media we may employ for future research.

No such objection may by any possibility obtain as to the limited finding of pneumobacillus of Friedlander, for on blood-serum it will outgrow any organism known to us, colonies growing to the size of a silver quarter while the *B. segmentosus* is grown to pin-point.

CONCLUSIONS FROM THE RESEARCH

The evidence seems indicative that the diphtheroids, particularly *Bacillus segmentosus* of Cautley, are concerned in the production of so-called common cold in its typical manifestation in the nose, and there is much evidence that it occurs in epidemic form.

The *Micrococcus catarrhalis* is much more general in its manifestation, and is, probably, also epidemic and productive of a rather more severe inflammation, though mild epidemics occur.

It seems likely that the symbiosis of these two organisms increases the virulence.

The pneumobacillus of Friedlander is much more concerned in chronic conditions and is probably identical with the *ozena bacillus*.

The pneumococcus of Fränkel flourishes in any part of the upper respiratory tract and, when virulent, has been found in pure culture.

Clinically the segmentosus infection is most likely to be in the nose, seldom in the trachea, but may cause otitis media; *Micrococcus catarrhalis* is most apt of all to invade the larynx and trachea, but may occur in the ear or nose and with variable virulence. The pneumobacillus is mostly confined to the nose and sinuses.

Influenza is conspicuous by its absence.

Pyogenic cocci are non-pathogenic locally, except as secondary invaders, and the probability is that only a limited number of strains are concerned in causation of acute infections on the mucosa, and these are not genuine coryza.

The bacterial flora of the nose in America probably does not differ materially from that of other countries, but must of necessity be governed largely by environment, occupation, social position and epidemics as to the ratios of finding.

ABSTRACT OF DISCUSSION

Dr. E. R. LEWIS, Dubuque, Iowa: In considering the pathologic conditions of the nasal and accessory nasal tissues, it must be remembered that a majority are due directly to infections, and of the remainder a large number are due indirectly to preexistent or coexistent infections. The subject of Dr. Walter's paper is, therefore, of practical interest to all who have to deal with these conditions. Inasmuch as there are involved two widely differing antagonists, the invading organism and the invaded tissues, analysis must proceed from two widely differing standpoints, that of the bacteriologist and that of the clinician. Observations which are to form the basis for deductions as to the bacteriologic or the clinical side of the matter must be made by experts and the bacteriologic expert should not dwell in the body of the clinician, and vice versa.

Among the deductions, certainties may or may not present; uncertainties are bound to. Undue emphasis should be spared the former and accorded the latter.

The fundamental reasons underlying the immunity of certain tissues and the susceptibility of other tissues apparently similar, in the same individual, to the same infection, may not be forthcoming. For instance, a gonococcus, bathing in mucous emulsion the newly born head, harms not the oral mucosa, or the nasal mucosa, but does attack the ocular mucosa. Yet that same oral mucosa, scatheless from its encounter with the gonococcus, falls easy prey to the lepto-*thrix* or *saccharomyces* infections, which in turn do not attack the conjunctivæ; the same nasal mucosa offers but weak resistance to pneumobacillus or streptococcus. Why? The Morax-Axenfeld bacillus conjunctivitis proceeds uninterrupted in the presence of bichlorid of mercury or silver salts but succumbs to zinc sulphate, whereas the more virulent gonococcus conjunctivitis subsides under the influence of silver salts but is not affected by zinc sulphate. Why? Questions like these must remain unanswered until careful investigations, patiently pursued and zealously guarded against error, shall have built up little by little a knowledge of the subject founded on truths proved by oft-repeated observations. I wish to express the appreciation which I am sure we all feel in regard to Dr. Walter's patience and energy.

I want to voice a suggestion concerning nomenclature which may be of some practical value. In speaking of the pharyngitis, tonsillitis, or rhinitis due to the *Bacillus diphtheria*, we are wont to use the terms nasal diphtheria, diphtheritic tonsillitis or diphtheritic pharyngitis. In speaking of other forms of pharyngitis, tonsillitis or other inflammation specified according to site, of known etiology, should we adopt the custom of using etiologic terms, it seems to me we should have made a step in advance, albeit a small one.

Dr. W. S. ANDERSON, Detroit: Why do infections of the mucous membrane of the lower respiratory tract occur? We all have patients who very seldom have an acute cold, and we have other patients who repeatedly have acute colds. We know that the lower animals are comparatively free from these infections. Why? What is there in the normal mucous membrane of some persons that resists infection while that of others does not? As I understand it, the normal respiratory tract is sterile, or nearly so. In the nose there are always a few micro-organisms but they do not thrive on a healthy mucous membrane. Going downward we find fewer and fewer germs until the tract below the vocal cords is always sterile in a healthy subject. But, in the presence of an acute cold there will be an abundant growth of organisms along the whole respiratory tract. Why? I have done some work in animals and it is easy to show that the lower respiratory tract is sterile but in many conditions it becomes infected. The mere closing up of the nose of a dog will be followed by a copious growth in the lower respiratory tract. Now we are coming to believe that many of the infectious diseases gain entrance through the mucous membrane of the respiratory tract, meningitis, diphtheria and so forth. In many of these there are local lesions of the mucous membrane, and yet if you attempt to reproduce these lesions in the lower animals you will fail. I have tried over and over again with the Klebs-Loeffler bacillus and have always failed,

and yet if we inject the organisms into the blood of the animals, they will die immediately or in twenty-four to forty-eight hours. The same thing occurs with the organism of pneumonia. If you rub it on the mucous membrane of the respiratory tract you will get no results at all. Why is the membrane in some cases so resistant? If we could learn what the local condition of the respiratory tract is that favors infection it would explain a great many conditions.

Dr. WILL WALTER, Chicago: Infection of the normal mucosa was not investigated but I reported the investigations of others who compare the normal with the abnormal. As to resistance to infection, of course there is the local resistance and the general immunity to be considered. There is also a variation in virulence of infectors and doubtless a specific local resistance. These are the problems which the laboratories of the world are trying to solve and which may not be answered offhand. In obstructed noses we have from mechanical causes practically a stasis and hence lowered local resistance. The opsonic index may be as high as 2 or 2.50 and still you get infection because of this stasis and the consequent poor local resistance. If the nose is shut off from its function by such abnormalities or by being held closed infection naturally occurs lower in the tract. Protection against such infection is one of the reasons for the existence of the nose.

A CLINICAL STUDY OF A CASE OF PSEUDO-
LEUKEMIC ANEMIA OF INFANCY

(VON JAKSCH) *

THEODORE J. ELTERICH, M.D.

PITTSBURG, PA.

In 1889, von Jaksch proposed the term "anemia pseudoleukemica infantum" to designate a pathologic picture characterized by oligocythemia, oligochromemia, considerable permanent leukocytosis, enlarged spleen, slightly enlarged liver, and, sometimes also, enlarged lymph-nodes. Its identity as a distinct disease has been seriously questioned by some authorities on diseases of the blood. Notwithstanding, however, we find in a certain number of infants suffering from a severe form of rachitis or hereditary syphilis, a symptom-complex which is entirely apart from the pre-existing disease.

A number of German authors, Japha, Fischl and Geissler and also some Italians include the grave infantile anemias in the secondary anemias with a toxic basis, practically as a middle condition between anemia and leukemia. Japha does not regard the spleen as the primary focus, and is of the opinion that it has nothing to do with the regeneration of the blood; this is based on the fact that the enlargement frequently becomes reduced before the blood-picture has become normal, while the extent of the enlargement does not correspond to the gravity of the anemia. Japha also believes that deficient new formation of blood constitutes the nature of the affection. At the same time, there may be an exaggerated destruction; but there are only a few cases in which the anemic (granular) degeneration of the red corpuscles is found as a positive evidence of blood poison.

A very notable work on this subject by Banti appeared in 1883. He believed that anemia splenica was a primary disease of the spleen, but he also considered it a splenic form of leukemia. In the case studied and described by him, there were marked fibrous changes in

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

the trabeculae and the follicles of the spleen; and a great diminution of the cells. There were many phagocytic cells containing red corpuscles; the bone-marrow was red and showed a lymphoid condition, but the lymph-nodes were enlarged. The spleen weighed 2 pounds, 7 ounces; the liver weighed 2 pounds, 12½ ounces. The blood showed a diminution of leukocytes and the red corpuscles were between 2,000,000 and 3,000,000 per cubic millimeter. Koplik reports nine cases in which the blood-picture was as follows:

The hemoglobin ranged from 28 to 65 per cent.; the count of red blood-cells or erythrocytes fell as low as 1,400,000 and in others was as high as 4,448,000; and the leukocytes ranged from 5,200 to 40,000 and 80,000 to the cubic millimeter. In all cases there were nucleated red blood-cells, normoblasts and megaloblasts from 7 to 15 per cent. In some cases the white cells varied from 10,000 to 80,000 to the cubic millimeter in a given case, with erythrocyte count of 2,699,999 to 3,799,999.

He regards von Jaksch's anemia as a severe secondary anemia with or without marked leukocytosis.

Monti and Berggruen report 20 cases. In six of these the red cells were below 1,600,000. Four cases proved fatal; one recovered in which the proportion of leukocytes to the red cells had been 1 to 12.

History.—The case which I observed was that of a male child aged 13 months, admitted to the children's ward of the Allegheny General Hospital, Pittsburg, Aug. 4, 1909. The father and mother are both of German parentage and are apparently in good health. There is no history of tuberculosis or syphilis. The patient was one of twins; the other died at the age of 2 months from diarrheal affection. The patient had always been a weak and delicate baby. He was breast-fed for a few weeks only, and then fed on various foods, principally condensed milk. He had always been pale and cries a great deal. He had never been known to smile.

Examination.—The child was very poorly nourished and anemic. His expression was often anxious; but, as a rule he seemed apathetic. The skin was dry and flabby. Numerous purpuric spots were seen in various parts of the body, particularly in the legs and over the right iliac region. There was considerable enlargement of the lymphatic glands in the cervical, axillary, and inguinal regions. The abdomen was distended. The anterior fontanel was open and about the size of a twenty-five cent piece. The child had but six teeth. The epiphyses of the forearms were enlarged. Rachitic rosary, well marked. Examination of the chest revealed a subacute bronchitis. The heart-sounds were clear and distinct. The liver was found to be enlarged, extending several finger-breadths below the costal cartilages. The spleen was enormously enlarged, the tumor extending far below and to within half an inch of the umbilicus. The notch of the spleen could be felt plainly. There seems to be some pain on palpation. Examination of urine was negative. The examination of the blood showed 27,500 whites, 2,500,000 reds and 45 per cent. of hemoglobin.

Course of Disease.—The foregoing is a description of the condition of the patient on admission to the hospital. He remained in the institution until the time of his death, Aug. 26, 1909, twenty-two days after admission. The progress of the disease was rather rapid and influenced to a considerable degree by intercurrent affections and conditions.

Temperature: On admission, his temperature was slightly above normal, but during the course of the disease varied from 101° to 104° F. partly due to a bronchopneumonia and a purulent inflammation of the middle ear, which occurred on the tenth and twelfth days, respectively, after admission.

Pulse: The pulse was rapid, never below 120, but, until shortly before his death, of fair quality.

Weight: From 15 pounds and 9 ounces, the weight fell rapidly to 13 pounds during the first week. Later there was a gain of about half a pound, which was followed by a rapid decline, reaching 11 pounds on the day of the patient's death.

Skin: In addition to the purpura, which remained and increased throughout the course of the disease, marked icterus was present shortly before death.

Lungs: While, on admission, only a few coarse râles could be heard over his chest, evidences of a bronchopneumonia were present on the tenth day and continued up until the time of his death.

Digestive System: Vomiting and diarrhea occurred frequently. It was extremely difficult to find any food which would agree with the patient. Whey and barley-water were about the only things which he retained.

Urine: At first the urine was normal, but later after the administration of arsacetin it contained a large amount of albumin, also a few hyaline and granular casts.

Blood: As stated above, at the time of admission, the patient had 27,500 whites, these gradually became reduced to 16,060; the reds were 2,500,000 and were reduced to 2,287,000. The hemoglobin remained about the same, 45 per cent.

Differential count:

Neutrophils.....	6.50 per cent.
Small lymphocytes	61.00 per cent.
Large lymphocytes	18.63 per cent.
Transitionals	1.47 per cent.
Eosinophils	0.28 per cent.
Basophils	0. per cent.
Neutrophils myelocytes	1.18 per cent.
Eosinophils myelocytes	1.18 per cent.
Normoblasts	9.76 per cent.
Polkilocytosis	per cent.
Polychromatophilic red cells	per cent.

Therapy.—The treatment at first was directed entirely to the digestive organs, calomel and bismuth being employed. Later the patient was given arsacetin hypodermatically in doses of 0.05 (gr. ¾) but, on account of the occurrence of albuminuria had to be discontinued. In addition, iron and stimulants were given.

Summary of Clinical Symptoms.—Rachitis, enormous enlargement of the spleen, moderate enlargement of the liver and lymphatic glands, purpura, icterus, bronchopneumonia, otitis media, gastro-intestinal indigestion, albuminuria.

Autopsy.—This was made by Dr. F. Proescher, Pathologist, Allegheny General Hospital.

Spleen, Macroscopic Examination: The spleen measured 10 cm. (4 in.) in length, 8 cm. (3.2 in.) in breadth, and 5 cm. (2 in.) in thickness. It weighed 163 gm. (5 oz. 15 grains) and was therefore about seven times the natural size of the spleen of an infant at that age. Its consistency was firm and it was deeply notched at the lower end. The surface was mostly of a light red color, but in some parts, a dark blue discoloration was seen. On section it was found to be of tough consistency. The follicular markings were obliterated. Numerous irregular but not sharply-defined areas were to be seen. These were about the size of pin-heads, of a grayish white color.

Spleen, Microscopic Examination: The capsule, as well as the trabeculae, was thickened. The connective tissue was deficient in nuclei and hyaline in appearance. The follicles were completely obliterated. Most remarkable was the great interstitial fibrous induration, which had caused almost complete obliteration of large areas of the pulp. This induration was seen to be partly in the shape of large, irregularly scattered areas of greater or less thickness, with remnants of pulp tissue, still enclosed; or, in the form of diffusely scattered, isolated fibers, traversing the entire pulp and passing between the pulp cells. These were exceptionally well defined by the Van Gieson staining. Both the smaller and larger vessels also showed considerable fibrous induration, especially the tunica adventitia, which was enormously thickened. In some places there was also a proliferation of the intima, which led to complete occlusion of the lumen. The enormously thickened adventitia presented a marked tendency to hyaline degeneration. The fibers of the connective tissues were conglomerated into hyaline masses

1. Arsacetin is sodium acetyl arsanilate, a compound derived from sodium arsanilate. It is claimed to be less toxic than sodium arsanilate and to possess the advantage of keeping well and being sterilizable without decomposition. Adult dose,—0.1 gm. (1½ grains) to 0.05 gm. (7½ grains.) For internal administration 0.05 (¾ gr.) 3 to 4 times daily. See N. N. R., 1910, page 36.

containing no nuclei. The lumina of the majority of the blood-vessels were empty, but, where they were filled with blood, erythrocytes pale and indistinct were found, beside which were seen many mononuclear and a few polymuclear cells.

In addition, there were seen cavities, either scattered or in groups, or even long and winding, and lined by a single layer of spindle-shaped endothelial cells. They were enclosed by a dense ring of round cells, some of which were surrounded by a thick hyaline non-nuclear tissue. That we were not dealing with blood-vessels was established by the fact of the uniformity of structure of the surrounding tissue, which allowed of no distinction of the different layers of the blood-vessels. We were in all probability dealing with a cystic dilatation of the lymph spaces. The pulp consisted of numerous blood-cells and round-cell elements of varying sizes, averaging from 3 to 6 microns in diameter. These mostly showed a round or slightly lobulated nucleus, with scanty protoplasm. Some of the nuclei were rich in chromatin, others showed only a framework of chromatin; many of the large mononuclear cells showed eosinophil granulations. In addition, a few spindle-shaped cells resembling endothelium cells were found. Large giant-like cells with phagocytic enclosure of red blood cells were scarcely seen.

Liver, Macroscopic Examination: The liver was 9 cm. ($3\frac{1}{2}$ in.) in length, 16 cm. ($6\frac{1}{2}$ in.) in breadth, 4 cm. ($1\frac{1}{2}$ in.) in thickness and weighed 345 gm. (11 oz. $\frac{3}{4}$ dram). It was of firm consistency, its edges were sharp and the color a yellowish red in some places, while in others it was more of a yellowish color. On section it was of a bright yellow or red color. The acinous delineations were quite plainly visible. At the periphery the acini were of a sulphur yellowish color; but, in the center more of a yellowish red and cloudy. Throughout the entire parenchyma there were numerous punctiform hemorrhages. The vessels were not enlarged. The tissues were moist and on pressure a thin, bloody fluid exuded copiously. The gall-bladder contained a large quantity of tough yellowish green bile.

Liver, Microscopic Examination: The parenchyma of the liver showed extensive tough infiltrations, especially the middle acinous zone. The liver cells in the center of the acini showed parenchymatous degeneration, partly sclerotic, partly necrotic. Irregularly scattered were seen larger and smaller hemorrhages (extramedullary blood formation) as well as larger and smaller round cells, with deeply stained nuclei. Some of these were round, others lobulated. The periportal connective tissue was very much thickened and infiltrated with round cells; also the walls of the hepatic artery and portal vein. Van Gieson's stain showed regularly distributed interstitial induration.

Kidneys, Macroscopic Examination: The two kidneys together weighed 100 gm. ($3\frac{1}{2}$ oz.); adrenals 6 gm. (90 gr.). The renal capsule was easily detached. The surface was lobulated and of a pale yellow, with numerous punctiform hemorrhages. On section the cortex was found to be enlarged, of a pale yellow color and slightly protuberant. The cortical marking was only present in form and was very much obliterated. Small white stripes were visible. The pyramids were somewhat more sharply defined by a more yellowish color. The left kidney presented practically the same appearance as the right one, but was somewhat redder in color. The mucous membrane of the renal pelvis was pale, with numerous punctiform hemorrhages.

Kidneys, Microscopic Examination: Both kidneys showed severe parenchymatous degeneration, with extensive necrosis of the epithelium. Slight hemorrhages into the glomeruli and uriniferous tubules were found. Hyaline masses were found in some of the canals, especially in the collecting ducts. On frozen section and with the Sudan stain fatty morphosis was found in some of the tortuous and straight uriniferous tubules.

Heart: The heart weighed 50 gm. ($1\frac{1}{2}$ oz.) and was well contracted. The musculature was of a cloudy, gray, yellowish color. Numerous small hemorrhages were found beneath the epicardium. The valvular apparatus was intact, the for-

men ovale closed. The intima of the large vessels, as well as that of the valves, was slightly discolored, a yellowish green.

Lungs: The lungs weighed 175 gm. (5 oz. 125 gr.). **Right lung:** In the upper lobe there was an irregular slightly depressed circumscribed spot about the size of a twenty-five-cent piece. The spot was discolored and dark gray in appearance. In the lower lobe there was also a spot about the size of a ten-cent piece, which was also depressed and dark gray in appearance. On section the entire pulmonary parenchyma seemed to be studded with the above-described areas. It was entirely airless, and on pressure a dark red turbid fluid exuded. **Left lung:** In the upper and lower lobes similar areas were found.

Stomach: The stomach contained a small quantity of fluid. The mucous membrane was atrophic and showed numerous punctiform hemorrhages.

Bowels: A small quantity of greenish white masses were found in the duodenum. The mucous membrane of the jejunum was also atrophic. In the colon a large quantity of fluid and dark green feces were found. The mucous membrane of the transverse colon was very much injected; that of the ascending and descending colon was pale.

The autopsy findings in this case correspond closely to those in the case described by Banti. Here we also find the fibrous changes in the trabeculae and the follicles of the spleen, and a great diminution of the cells. We also have a diminution of leukocytes and the red corpuscles.

The diagnosis of this case as belonging to the class of cases described under the term of pseudoleukemic anemia of infancy can scarcely be questioned. The low leukocyte count, the diminution of the red blood-corpuscles below half the normal, together with the enlargement of the spleen, moderate enlargement of the lymph-nodes distinguishes it from leukemia and simple or pernicious forms of anemia. Whether this case is to be considered a secondary anemia in connection with the rachitis with a toxic basis; or, as a distinct organic disease, it is difficult to decide. The organic changes in the spleen and liver would indicate a primary diseased condition of that most important blood-making organ, the spleen. The evidence seems about equally divided and in view of the fact that so far but few autopsies have been recorded in these cases, it is impossible to come to any definite conclusion in this single case. I hope that by having carefully studied and recorded the findings of this interesting case I have added a small mite to the literature of this important disease.

6101 Penn Avenue.

ABSTRACT OF DISCUSSION

Dr. J. F. HULTGEN, Chicago: In the last few years I have had a number of similar cases which have made me think a good deal of this question. The case just reported undoubtedly belongs to that class of anemias of infancy which we call, for want of a better name, pseudo-leukemia. Some of my recent cases have shown a combination of leukemic and leukanemic changes; that is, not only very marked qualitative and quantitative changes of the leucocytes, but also marked alterations in the number and form of the red blood-corpuscles. Others run into a true leukemia and end in death. Dr. Elterich's case does not belong to this last special class and I am glad he mentioned that. Assuming that all the leukocytes develop from the small lymphoid cell, those infections characterized by specific changes in the blood must be due to an irritation of the leucogenic system. Whether or not this condition is recognized at an early stage, or advances to a splenic anemia or Banti's disease before it is diagnosed makes no difference. It is the same disease, only a later stage. I think we are almost smothered by a multitude of names in the description of the so-called pseudo-leukemia of childhood. Any severe dis-

turbance of the infantile leucopoietic system may in the first place produce partial or complete leukemia. Whether we have a polynuclear or a mononuclear or a lymphatic leukemia, does not alter the case. It simply depends on the hastening or the slowing of the processes of maturation of the lymphocytes. Later on, after months or years the patients come to our offices, and finding a large spleen, ascites, etc., we call it Banti's disease. The pathogenesis of infantile pseudo-leukemia does not reside in the spleen alone. It depends on infectious, or toxi-infectious lesions of the lymphoid tissues. I think it is easy to believe that as long as there is some leucopoietic tissue left there may be an acute leucogenic crisis. The blood examination then would show a leukemia. A blood examination made later on will likely show a splenic anemia, or an *anémie primitive* of French writers, a leukanemia, or Banti's disease, etc. Or the patient may go on to a pernicious anemia. This is also easy to understand if we consider that in irritation of the leucopoietic cells we must also have a hematopoietic irritation. I think that all these anemias should be looked on as the results of an infection of the lymphoid or leucopoietic system in the gastro-intestinal canal, which may or may not be noticed at the time of its occurrence. Its various forms are nothing but the variations common to all individuals. In childhood the death of these patients is due to exhaustion. Perhaps there are toxic symptoms, but they usually die with the clinical picture of asthenia, though this is often preceded by bronchopneumonia. I think the abdominal symptoms are always at the bottom of this condition, though they are not usually recognized.

DR. C. F. WAHRER, Fort Madison, Iowa: I have seen three cases that would come under the author's name of the infection. The first patient, after five months, died. The second after three months died, and the third recovered. The recovery may throw a little doubt on my diagnosis, but I did the best I could with the means at hand. We had a symptom-complex of an affection that we may class under the diagnosis named by the essayist. The children all had the symptoms that have been named briefly by the author. There was anemia, there were purpuric spots and a history of syphilis in the ancestry of the first two; in the last one, a gastro-enteric trouble with numerous and profuse hemorrhages from the intestinal canal. The treatment in the first two cases was addressed chiefly to the origin of the disease, *i. e.*, the syphilitic condition, and in the last case it consisted mainly in the administration of Fowler's solution, iron and remedies addressed to the gastro-intestinal tract. This child, after ten years, is still in perfect health.

DR. THEODORE J. ELTERICH, Pittsburg, Pa.: I am not in a position to classify these cases according to their pathologic findings. I had only one case in which the diagnosis seemed positive. In one or two other cases no blood count was made and the patients died before they could be removed to the hospital for observation. The symptoms were those of rickets, with an enlargement of the spleen and anemia.

CHOKED DISC IN ITS RELATION TO CEREBRAL TUMOR AND TREPHINING*

ALFRED SAENGER, M.D.
Neurologist to the Hospital St. Georg
HAMBURG, GERMANY

When I was invited to be the guest of the Section on Nervous and Mental Diseases of the American Medical Association, and to read a paper before this famous body, I felt highly honored, and it was with the greatest pleasure and thanks that I accepted this invitation. Having leave to choose the subject I did not hesitate long and selected the important theme of choked disc in its relation to cerebral tumor and trephining.

There is hardly any point which has for so long a time been subject to as much controversy as the patho-

genesis of choked disc. In spite of numerous works, experiments, clinical observations and pathologic-anatomic investigations, we have not succeeded in bringing about an agreement between the various investigators on this topic. Just lately the old quarrel on the pathogenesis of choked disc has become active again in Germany.

Surgical experience being, to my mind, of great importance for clearing up the origin of choked disc. I was convinced that America would be the best forum for discussing this question, because America possesses a greater experience on the effect of and indications for trephining in cerebral tumor than we do in Germany, thanks to the studies and works of Taylor, Mills, Spiller and Frazier, De Schweinitz, Weisenburg, Putnam, Knapp, James Bordley and also to the new methods of Harvey Cushing, not forgetting, however, England's contributions, by Horsley, Gowers, Gunn and Leslie Paton.

The fact that I was an ophthalmologist at first and devoted myself to neurology later has brought it about that I have been occupied for twenty years with studying the changes of the fundus of the eye in diseases of the brain.

By request of Professor Uhthoff of Breslau, I made a report on the pathogenesis of choked disc before the seventy-sixth *Versammlung Deutscher Naturforscher und Aerzte* in Breslau in 1904. Since that date so much new work has been published, that I deem it necessary to give you a brief outline of the stand we take on this important question in Germany.

REVIEW OF WORK AND THEORIES ON CHOKED DISC

Tuerck was the first, who in 1853, when describing a case of cerebral tumor with retinal hemorrhage expressed the idea, that the changes in the fundus of the eye were due to increase of intracranial pressure. However, only in 1860 the scientific world became acquainted with the so-called choked disc through Albrecht von Graefe's work on complications of optic nerve-inflammation with brain diseases. Von Graefe saw the cause of choked disc in brain pressure, due to cerebral tumor, the sinus cavernosus being thus compressed and the voiding of both the vena ophthalmica and the vena centralis retinae being inhibited; bringing about dilatation and twisting of the retinal veins as well as edematous swelling of the optic disc. He explained the inflammatory changes, first, as originating from retinal extravasations of blood; secondly, from the irritating effect of swelling of the optic disc, still increased by toughness of the scleral ring.

Von Graefe's hypothesis, however, soon encountered opposition. Hughlings-Jackson took the optical affection for a reflex symptom, but it was the anatomic facts found by Sesemann which principally disproved the theory. It was he who proved that the central retinal vein has an off-flow into the facial veins, quite independent of intracranial pressure. Moreover, Sesemann argued that compression of the sinus cavernosus could not be effected as easily as one might think. Later these statements made by Sesemann in 1869, though accepted everywhere, even by von Graefe himself, have met opposition from the well-known anatomist, Merkel, and from Gurwith, who, on the basis of extensive anatomic investigations, argued that the greatest part of the orbital venous blood flows into the sinus cavernosus. Quite recently J. Tudeich and Krüdener have endeavored to uphold the old theory of von Graefe

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

for those cases of choked disc, in which intracranial pressure is localized.

The second principal theory of choked disc is the one brought forward by Schmidt-Manz's theory of mechanical transportation, based on Schwalbe's discovery of the communication between the intravaginal space of the optic nerve and the intermeningeal space of the brain. According to the views of both these authors a vaginal hydrops of the optic nerve is caused by increase of intracranial pressure, for instance, owing to cerebral tumor, and consequently, incarceration of the intraocular end of the optic nerve would occur, choked disc henceforth resulting.

Von Schulten, by his experiments, confirmed Schmidt-Manz's theory, which was readily accepted, but soon also vigorously combated.

In 1881 the famous ophthalmologist, Leber, brought forward a new theory of choked disc before the London Congress. According to Leber it is a real inflammatory process, a papillitis, not preceded by any stage of pure edema or pure venous stagnation. The originators of inflammation are in the fluid which has come from the intermeningeal space of the brain into the intervaginal space of the optic nerve. Even though a real hydrops of the optic nerve were absent, yet choked disc could occur, because the point is not the quantity of the fluid, but its quality.

Deutschmann supported the theory of Leber by several works and established the hypothesis that the cerebral tumors produce toxins, which call forth inflammation of the optic nerve and its sheaths.

Besides Hughlings-Jackson, Gowers also was of the opinion that intracranial tumors could cause neuritis optica through irritating influences acting as foreign bodies.

In modern times Zellweger and Elschnig, the latter of whom disposed of twenty-eight cases of choked disc, which he examined microscopically, declared themselves for the Leber-Deutschmann inflammatory theory. Elschnig says, that in intracranial tumors the primary is a neuritis of the optic nerve, whereas edema is secondary and only an accompanying symptom.

Liebrecht, in 1902, is likewise of the opinion that the primary manifestations are inflammatory changes within the optic sheaths, in connection with which a stagnation of the lymph occurs in the optic nerve and disc.

We may quote, among other theories, the one of Parinaud. According to him the various intracranial diseases call forth a stagnation in the optic disc only in the case of complication with hydrocephalus internus. With this is connected edema of the brain, which by itself affects an equivalent edema of the optic nerve. This may be followed by inflammation—*neurite adéquateuse*. In the presence of edema of the optic disc, according to Parinaud, the diagnosis of hydrocephalus and cerebral edema only is admissible.

Lourdill accepted Parinaud's theory. However, he considered the primary change to be an edema of the ependymalgia, which continues in a direct way in the glia of the chiasm and of the optic nerve.

Also, according to the opinion of Ulrich (1887) cerebral edema propagates into the optic nerve.

In 1904 extensive researches (forty-six eye examinations) made by Kampherstein from Professor Uhthoff's clinic at Breslau, proved that the most invariable symptom consisted in an interfascicular edema of the optic nerve. For this reason in most cases choked disc is nothing but an edema propagated from the brain, penetrating into the optic nerve, and through it into the

optic disc by the way of the lamina, creating hereby incarceration of the intraocular optic nerve-end a swelling within the rigid scleral ring.

Benedict and Adamkiewicz occupy a position apart with regard to the pathogenesis of choked disc. The former believed the vasomotor nerves to be irritated by the tumor, thus causing an inflammation of the optic disc by reflex. The latter regards the choked disc as the result of a neuroparalytic inflammation due to irritation of the trophic centers proper to the optic nerve.

Knapp, Deyl, von Gross and Yamaguchi published cases to prove the causation of choked disc through compression of the central vein.

PRESENT-DAY THEORIES

In our days we seem to be reaching a compromise. Thus Greeff expressed himself as follows: "It seems to be the case that stagnation of the cerebrospinal fluid plays an important rôle, but that inflammatory irritations are concurring."

In 1907 I published a treatise, in which I pointed out again energetically my views, which I had presented in 1901, viz., that a palliative operation should be performed in cases of inaccessible brain tumor in order to avoid threatening blindness.

SUMMARY OF CASES

I disposed of nineteen cases. In two of these choked disc decreased only after the trephining hole had been enlarged, allowing a great outflow of cerebrospinal fluid. In two cases decompression had no effect whatsoever as far as the choked disc was concerned. These were cases of extraordinarily large, rapidly increasing brain tumors. In one case only, a tumor of the base, the operation was followed by very high fever and rapid exitus. No doubt it must have been one of those cases which have just been described by Dr. George J. Jacoby in New York, because post-mortem examination did not explain the cause of the hyperthermia.

In all the rest of the cases the effect of decompression on choked disc was obvious.

In one case I was able to observe, as did Cushing in two cases, a decrease of choked disc directly after decompression.

I apply this term in the sense of Frazier, as he explained in an address before the Toronto Academy of Medicine last year. He said: "The term decompression implies not simple trephining, but the removal of the dura."

DECOMPRESSION OPERATION

In all my cases decompression has been done in this sense. Often I could observe that the choked disc decreased in the measure in which the outflow of cerebrospinal liquor increases. As a rule it takes several weeks or months to flatten down.

In order to obtain good results as far as vision is concerned it is imperative to operate early, viz., while the visual power is still of use. In some cases I have seen vision improve considerably after decompression.

E. von Hippel, in his studies of the literature in 1908, arrived at the same result. He does not, however, give his personal experience.

Philip Coombs Knapp, in 1906, published a vast number of cases in which no tumor was found by operation or in which decompression alone was done. Knapp affirms that the development of choked disc is arrested only in about half the cases. I regret very much that Dr. Knapp is not present. I would ask him whether he

any ophthalmologist would be willing to stake his reputation on the diagnosis; nevertheless, when the disk declines and the patient recovers there is perfect vision. I am confident that it is not possible to locate the tumor by a study of the disks. While there are suggestive signs they are by no means of positive value. As an example we had a long list, possibly twenty-five or thirty patients, with the greatest choking on the side of the tumor. We were almost persuaded. Then came a series of several cases with the greatest choking on the opposite side. As a rule, however, the greatest choking—or rather the greatest change in the optic nerve—is on the side of the tumor, probably 65 or 75 per cent.

Tumors of the cerebellum, as a rule, give rise to a greater swelling than tumors farther forward. Anatomic variations in the optic nerves make a difference in the degree of swelling on the two sides. Consequently it must be expected that tumors, even of the same histologic structure, will result in a difference in degrees of swelling in different individuals. In our experimental work on animals, where the choked disk was produced with simple saline solutions, the greatest choking usually occurred on the contralateral side. My impression is that the same rule will hold good in patients with intracranial injuries in whom there is hemorrhage. Wherever there was solid pressure, such as produced by paraffin, the greatest change was usually on the same side.

One thing is absolutely certain: a decompressive operation should always be performed when one is dealing with a stationary or increasing choking of the optic disk. There is no excuse for sitting by and waiting for vision to decline; every bit lost may be gone forever, for one may have waited for the beginning of a very rapid end. And it is well to remember that if the sight is not obliterated by pressure, it may be by the new connective tissue which forms in the nerve and in the disk—as the result of long irritation. Like other scar tissue this will shrink, and as it shrinks it snuffs out the life of the nerve.

DR. A. SAENGER, Hamburg, Germany: I am much gratified that my paper has elicited such a lively discussion, and, above all, that Dr. Parsons, the eminent ophthalmologist of London, agrees with me. He declares that choked disk is not an inflammation but an edema of the optic papilla. This statement is very important as coming from a very competent authority on pathologic anatomy in the field of ophthalmology, and also as coming from the English school. We all know how tenaciously the conception of the inflammatory nature of choked disk has been maintained in England. Even Gowers, that well-known authority, has championed this view.

I hope that now there will be a general acceptance of the view that the increased pressure on the brain is the main factor in the origin of choked disk, manifesting itself in the edema of the papilla. There may be inflammatory changes besides, but they are of secondary nature. The inflammatory theory of choked disk, as Leber and Deutschmann propounded it, can no longer be maintained. I am familiar with Dr. Bordley's work on the subject, done in collaboration with Cushing. I visited the famous Johns Hopkins Hospital at Baltimore a few days ago and was amazed at the extraordinary amount of material in the field of brain surgery which is at Harvey Cushing's disposal there. I had also an opportunity to see this master in his special field of science operate. I admired the originality of his technic, the position he gives the patient and his extreme caution and conscientiousness in the execution of the operation. We stand on the same ground in respect to early trephining with a tumor in the brain. Cushing, however, goes beyond me in this. He trephines even before actual choked disk has developed, while I prefer to wait until with existing choked disk the vision begins to show impairment.

My warning to refrain from operating too early is based on my last series of five cases, on the latest experiences with pseudotumors, swelling of the brain, chronic meningitis and brain syphilis with negative Wassermann reaction. The deceptive cases of brain syphilis, which so often runs a disguised course, should be constantly borne in mind, and specific "mixed" treatment should invariably be given a trial before any operation on the brain. I have occasionally encountered unilateral choked disk, far more frequently on the side corresponding to the tumor, but still, though rarely, sometimes on

the opposite side. I am persuaded that individual changes in the optic foramen are responsible for the lack of development of choked disk. In one case I was able to determine this to be the fact, although it is technically a difficult matter to demonstrate beyond cavil this narrowing of the optic foramen. It is to be hoped that some research worker may turn his attention especially to this question ere long.

DISLOCATION OF SHOULDER-JOINT COMPLICATED BY FRACTURE

WITH REPORT OF TWO CASES

JOHN S. McEWAN, M.D.

Surgeon to Church Hospital; A. C. L. Surgeon
ORLANDO, FLA.

The fracture of a dislocated humerus is so rare an accident that up to 1894 a most careful search had revealed only 117 cases, and the surgeon reporting this fact adds that no single observer has met more than five.¹

The text-books² take this subject up in a very limited manner.

This injury is usually caused by the patient having received a heavy blow upon the shoulder, or having fallen on the shoulder or on the outstretched hand or elbow. Rare as these accidents are, a recent authority³ (1906) says that they are more frequent and more important than fracture of the scapula, though the latter, as well as fracture of the clavicle, also occurs.

In treating dislocation complicated by fracture the dislocation should be reduced as soon as possible by one of several methods in use, the one generally employed being that described by Kocher in 1870, and is described by Keen as follows:

"The patient is seated, and the surgeon stands facing him and on his injured side. He bends the elbow and grasps it in one hand, while he seizes the wrist with the other. He then bends the elbow, and adducts the arm until the elbow touches the trunk. The arm is immediately rotated outward as far as it will go, and being thus adducted and rotated outward the elbow is carried well forward and upward. The whole arm is then rotated inward, so that the hand sweeps over the chest, while the elbow is brought back to its original level. The bone slips into place with a hardly perceptible click in a successful case, and the shape and movement of the joint are at once

* Read before the Association of Atlantic Coast Line Railway Surgeons, May 17, 1910.

1. Since the article written by Dr. Charles McBurney and Dr. Charles N. Down (Ann. Surg., April, 1894), there have been several contributions on the subject, the principal ones being as follows:

Andrews, E. W.: Surg., Gynec. and Obst., November, 1905.
Royster, H. A.: The Management of Dislocation of the Shoulder-joint Complicated by Fracture of the Neck of the Humerus. The Journal A. M. A., Aug. 10, 1907, p. 487.

Mason, J. M.: Ann. Surg., 1908, xlvii, 672.
Flint, C. P.: Am. Jour. Surg., 1908, xxii, 161.
Spencer, W. G.: Proc. Roy. Med. Soc., London, 1908-9, II, Clin. Sect., p. 226.

Toubery: Rev. internat. de méd. et de chir., 1908, xiv, 183.
The most valuable contribution during the year 1906, however, was the article written by Dr. Robert Jones on Certain Injuries Associated with Displacement of the Head of the Humerus, Brit. Med. Jour., June 16, 1906, p. 1385.

restored." All this must be done slowly and gently to avoid causing a fracture at the surgical neck. "The Kocher method is based on the exact knowledge of the pathologic conditions, and is the most perfect one for this reason."

The traction method is employed when it is impossible to reduce the dislocation by the above means. There are several ways of applying this, a simple one being to grasp the arm above the elbow and make a steady traction downward and outward, then gradually abduct the arm until it is nearly at right angles with the body. Pressure is then made over the head in the axilla.

Another method is that of Stimson, in which weights are attached to the elbow or wrist (the arm hanging free of the floor as the patient lies upon a table). Ten pounds are added at times one or two minutes apart until 40 pounds have been reached, and in from five to fifteen minutes the head is advanced toward the glenoid cavity by adducting the arm against the fist that has been placed in the axilla.

In fractured dislocations an anesthetic should be administered and "every method should be tried in order to reduce the head before performing operation." Where other efforts fail McBurney's operation is advised, in which an incision is made in the soft parts on the outer aspect of the upper fragment, extending down to the bone, and a hole is drilled in the latter, through which a stout hook is inserted and direct traction made on the upper fragment in the proper direction.

Dr. Robert Jones reports twenty-two cases of fracture of the head of the humerus associated with dislocation of the shoulder, and after advising the reduction of the dislocation as soon as possible by one of the accepted methods, he adds: "Having reduced the dislocation, the fracture of the humerus is of comparatively little moment and need not be dwelt on." Perfect apposition is not necessary to good results, and he strongly advises against the wiring of fragments in fracture through the surgical neck, his experience with many hundreds of cases of this fracture showing that wiring would not have been of service in a single instance. In order to prevent stiffness of movement after the parts have united, massage and passive movements should be regularly practiced between the fourth and eighth weeks.

For fracture of the clavicle and scapula with displacement the dislocation should be reduced and for the latter cases the arm need only be kept at rest and protected from accidental injuries by the use of a shoulder cap, the use of the axillary pad also being considered useless and even dangerous by some surgical authorities. When the clavicle is fractured Sayre's method of strapping the arm is advised.

CASE 1.—History.—The patient came into my office Sept. 30, 1909, saying that on July 18 he had fallen out of a wagon and struck on his right shoulder. He could not move his arm; pain was severe, but he got up and went to a physician, who said that he had a dislocation. This physician tried to reduce it without an anesthetic, but could not, so sent him to another physician in an adjoining town, who, on July 20, gave the patient an anesthetic. When he woke up he was told that his arm had been put back in place and that if he would keep it in there for three weeks it would be all right. He removed the bandage at the end of the three weeks and found his arm in the same position it was before. His arm had been paining him ever since and he could not use it only to a limited extent.

Examinations, Treatment and Result.—The first examination showed shortening of the humerus, very small amount of adduction and abduction, anterior and posterior motions being limited, and on examination with the x-ray made a probable diagnosis of fracture dislocation. I sent him to the hospital, gave

him an anesthetic, and on manipulation found a fracture at the surgical neck of the humerus and anterior dislocation. I was unable to reduce his dislocation, so put the arm up in as good position as possible, and when the patient had recovered from the anesthetic advised him to let me operate and put his arm in proper position. This he refused to do and went home. I examined the patient on May 1. He said that he had no pain, but he could not move his arm very much, although his movements were greater than when he left here. He had no adduction and very little abduction, anterior and posterior movements were good. He still declines operation, because, as he says, "My arm doesn't hurt me and I am getting better all the time."

CASE 2.—History.—The patient, who was referred to me by Dr. H. on February 18, said that the last he remembered was that he was standing at a lunch-counter drinking coffee; a policeman told him he fell over and had a fit and that they picked him up and walked him home. This was on Nov. 2, 1909. A physician was sent for on November 3, who anesthetized the patient and put his arm in splints. Not having obtained any use of his arm, the patient went back to the physician on December 3, and was again given an anesthetic and the dislocation supposedly reduced again. This time the arm was put up in plaster of Paris; the splint was left for three weeks and then taken off. The arm was still severely painful and useless.

Examination, Treatment and Result.—On careful examination, including the use of the x-ray, I found a retroglenoid dislocation with fracture of the anatomic neck of the humerus. I advised operation and on Feb. 22, assisted by Dr. Edwards, I opened the joint, using the anterior incision, took out the head of the bone, eurented the glenoid cavity and put the arm up in position, kept it immobilized until the wound healed, and since then the patient has had constantly passive and active motion with massage and as a result is getting good use of his arm. I believe that if I had used the posterior incision I would have had less difficulty in removing the head of the humerus.

In comparing my two cases I find that the patient on whom I operated has the most serviceable arm and therefore, I should advise all persons who have dislocation of the humerus with fracture in which reduction has not been obtained and there is restricted motion to submit to an operation.

All patients with unreduced retroglenoid fracture dislocation should be operated on, using posterior intermuscular incision recommended by Dr. W. G. Spencer.

THE CONTRIBUTION OF EXPERIMENTAL TO HUMAN POLIOMYELITIS *

SIMON FLEXNER, M.D.
NEW YORK

Epidemic poliomyelitis has within three years become a common and widely distributed disease in the United States. Prior to 1907 the epidemic disease occurred rarely, only, in this country. Since 1907 it has prevailed from the Atlantic to the Pacific Ocean, and probably few states have entirely escaped its ravages. Judging from the fragmentary reports which have come to my attention it would seem as though the southern states had escaped wholly or in large part, but this apparent discrepancy may result from failure either to recognize the nature of the epidemic disease or to report on it, or may be due simply to the circumstance that the fact of its occurrence in the South has not chanced to come to my attention.

*A rather complete bibliography accompanied this article and is included in the author's reprints. Because of the space required, it is omitted from THE JOURNAL.

It is significant in respect to this point that within the period mentioned epidemic poliomyelitis has prevailed in Cuba. Before 1907 epidemic poliomyelitis had been becoming more frequent in northern Europe, and particularly, so far as reports indicate, in Scandinavia. Beginning in 1907 or thereabout a pandemic of the disease arose. The United States, Austria, Germany and latterly France have certainly participated in the epidemic outbreaks. Whether still other countries have been similarly visited I cannot say, but it is highly probable that they have.

It is a matter of significance that the original foci of the epidemic disease in the United States, occurring in the summer of 1907, were among the Atlantic seaboard, and that the two centers of population most seriously affected were about Greater New York and Boston. The particular point of importance in this regard arises from the fact that those two centers of population receive first and in most concentrated way the immigrant population from northern and eastern Europe. Since, moreover, the best established endemic focus of epidemic poliomyelitis recorded in the last decade or two has been the countries of Scandinavia, the further fact becomes significant that the second large isolated outbreak of the disease in this country occurred in that part of the middle west, namely about Minnesota, which receives a large influx of immigrant population from Norway and Sweden.

CONTAGIOUSNESS

The studies especially devoted to the question of the mode of spread of poliomyelitis, which have been conducted with unusual energy and perspicacity in the last few years, would seem to have rendered contagion highly probable. If the views respecting the manner of the transfer of the contagion put forward with good reason should become established, the explanation of the extension of the epidemic centers of poliomyelitis from northern Europe to America will have become obvious. The data collected in Scandinavia indicate that the contagion can be carried by intermediate persons from the stricken to the healthy, and from patients not frankly paralyzed, but suffering with slight or so-called abortive attacks of the disease. Moreover, the incubation period of the disease would appear to vary within considerable limits, being sometimes not more than two or three or four days in length and at other times as much as twenty days, the average being eight or ten days, and thus affording opportunity for the transportation across the Atlantic Ocean of the incipiently infected. This particular problem would receive considerable illumination from facts which are ascertainable, such as the number approximately of recently arrived immigrants who developed poliomyelitis in this country since 1907. I am not aware that any effort has been made in the course of the several recent extensive investigations of the epidemiology of the affection to elucidate this important point.

The idea of a contagion in respect to epidemic poliomyelitis is not a new one, but appeared in the literature more than a quarter of a century ago, and of late has been frequently invoked. The clinical course of the disease indicated an infectious origin, but up to very recent times no convincing knowledge concerning the nature of the agent causing epidemic poliomyelitis existed. Various bacteria, and especially certain cocci, have from time to time been isolated in cultures from fluids obtained by lumbar puncture from patients suffering from the epidemic disease, or from specimens of the central

nervous system removed from victims at autopsy. These bacteria did not conform to one species or group of micro-organisms, and did not suffice to set up poliomyelitis in animals. They can be accounted for more satisfactorily as contaminations or secondarily invading bacteria than as the cause of the disease. The epidemic of 1909 in this country, in France and in Germany, led to a renewed study of the nature of the infection, in the course of which the more subtle and recent methods of bacteriology were employed. These methods led almost simultaneously in the United States by Dr. Lewis and myself and in France by Landsteiner and Levaditi, to the discovery that the infectious agent was an extremely minute micro-organism that readily passed through the pores of earthenware filters and constituted, therefore, an example of the so-called filterable viruses, of which at the present time several examples are known to cause infectious diseases in man and the lower animals. The filterable nature of the virus has now been confirmed wherever the subject has been accurately investigated. On acquisition of the fact of the nature of this virus, and of the further fact, on which the discovery of the nature of the virus actually depends, that both the higher and lower monkeys are subject to the experimental disease, rests the recent great advances which have been made in the investigation of epidemic poliomyelitis.

EXPERIMENTS WITH MONKEYS

It was predictable that the effort would be made as soon as circumstances favored to transmit poliomyelitis to monkeys. Since the disease appeared not to be transferable to the more common species of warm-blooded animals, usually available in laboratories, it became imperative to attempt its transfer to other species more nearly related to man. The last few years had indeed afforded several brilliant instances in which progress in determining the nature or the conquest of important infectious diseases had resulted from the use of apes and monkeys. Two examples illustrative of this statement are afforded by syphilis and epidemic cerebrospinal meningitis. Hence, in 1907, when the first epidemic appeared in New York and vicinity, we endeavored to transfer poliomyelitis from human beings to monkeys. Unfortunately we were at this time limited merely to fluids obtained by lumbar puncture from cases at different stages of the disease. I say unfortunately for the reason that we had the idea originally of bringing the supposedly infected material directly into relation with the nervous systems of monkeys. This we indeed did with the fluids obtained by lumbar puncture, from which we failed entirely to produce any symptoms that we could discover, including paralysis. During the epidemic of 1907 we did not secure organs from a case of pure infantile paralysis, and we failed, therefore, in our intention to inoculate monkeys from the spinal cord. Had we secured such material the discovery of the nature of epidemic poliomyelitis would, it is fair to assume, have been made two years earlier than it was. It was not until September, 1909, that we secured the spinal cord from two cases of infantile paralysis in human beings, which specimens were employed for the inoculation of monkeys by direct injection of an emulsion into the brain through a trephine opening. The first inoculations were successful. The animals immediately after their recovery from the ether anesthesia were lively and normal. They remained apparently in perfect health for a number of days, when paralysis set in. The spinal

cord derived from these animals was and is still being employed to transmit the infection to still other monkeys.

During the summer of 1909 Landsteiner and Popper published an account of a successful inoculation of two monkeys with the spinal cord derived from a case of infantile paralysis in a child. They employed the peritoneal cavity as the site of injection, which led to the development of paralysis, but in endeavoring to continue the transfer of the virus by intraperitoneal injection of other monkeys they failed entirely. Strauss and Hutton in this country, who repeated in the late summer or early autumn of 1909 the experiments of Landsteiner and Popper, met with the same interruption of their work. Using the peritoneum as the avenue of entrance of the virus, they succeeded in producing paralysis in a monkey inoculated with the human cord, but failed to produce paralysis when they transferred to other monkeys a suspension of the spinal cord of the paralyzed monkey. In view of these experiments, and of still other similar ones made by different investigators, it is probable that the virus contained within the human cord is on the whole more active when implanted in the monkey than is the virus contained within the monkeys' spinal cords that is derived by proliferation immediately from the virus of human source. The question for the moment remains open whether this disparity depends on the quality of the virus or the number or state of concentration of the organisms. Later studies, to which reference will be made, indicate that the virus of poliomyelitis is subject to qualitative variations, from which it follows that the sudden change of host might tend to a reduction in the potency of the virus, the fact of which reduction is exhibited when the virus is compelled to traverse a considerable territory and to overcome certain natural obstacles before it reaches the central nervous system, on which it became implanted. The fact of this qualitative change is far less apparent when the altered virus is brought immediately into relation with the tissues of the nervous system.

CLINICAL EFFECTS OF INOCULATIONS

In noting the clinical effects of the inoculations we have paid attention to a number of conditions and signs that had already been indicated by observations made on the human affection. We have, therefore, observed an incubation period represented by the interval elapsing between the time of inoculation and the appearance of the first definite paralysis, which incubation period includes certain manifestations which have been noted as prodromal symptoms. Thus the shortest period noted as elapsing between the inoculation and the onset of paralysis has been three or four days and the longest period thirty-three days, the average period being eight or nine days. The prodromal symptoms consist of a state of undue nervousness and excitability on the part of the inoculated monkeys, or inability to fix the gaze, with which is associated a wrinkle and mobile rather than smooth and placid cast of countenance, and an erection of the hairs over the body. These symptoms are most marked for a period of from six to eight hours before the onset of the paralysis. We have not noted any constant elevation of temperature or gastro-intestinal disturbance. The onset of paralysis either when the prodromal symptoms have occurred, or when they have been absent or undetected, tends to be sudden. The paralysis affecting any of the larger groups of voluntary muscles

tends to be accompanied with other weak or partially paralyzed groups of muscles. In certain animals the medulla was first affected, and in them death sometimes occurred before the development of actual paralysis. In respect to location, the lower and upper extremities were affected oftener than the muscles of the trunk, and the spinal paralyzes were much more frequent than the cerebral. Sensory disturbances occurred, but their investigation was much less satisfactory than the investigation of the motor disturbances. In other words, there is a striking similarity between the frank examples of epidemic poliomyelitis, whether occurring spontaneously in man or produced experimentally in monkeys. A further correspondence exists in this: Slight and evanescent or abortive attacks of the disease have been described in human beings, cases the nature of which would not be suspected were it not for the fact that they occur during the prevalence of epidemics of frank paralysis; and similar abortive or evanescent attacks have been noted among inoculated monkeys, but rarely. There is, however, one important point in which the experimental disease happily differs from the human affection. The mortality in the human affection rarely exceeds 10 per cent. of those frankly attacked, and frequently it is much less than that. The experimental disease, on the other hand, has terminated fatally in about one-half of the first series of animals inoculated, and in a much larger proportion of the later ones. Hence the experimental disease is more highly fatal than the spontaneous disease.

PATHOLOGY

A still further correspondence between the spontaneous and experimental disease is found in respect to the pathologic changes or lesions. The gross lesions visible to the naked eye present in the spinal cord and medulla of monkeys consist of congestion and hemorrhage into the gray matter, chiefly but not exclusively confined to the anterior horns. On the other hand, the general appearance of the spinal cord, medulla and brain are not greatly altered, and the visible effects are no proper measure of the damage inflicted by the virus.

The microscopic lesions are more severe and widespread in the spinal cord than in the brain, and more pronounced in the gray matter and membranes of the cord than in the white matter. No part of the spinal cord, including the medulla, is entirely free from lesions, but the severest lesions tend to occur at levels corresponding to the groups of muscles most severely paralyzed. The meninges show more or less diffuse infiltration with round cells, the greatest accumulations of which are about the blood-vessels, where thick collars of cells often exist. The infiltration is within the adventitial coat, while the muscular coat and the intima remain intact, although the lumina of the vessels are often encroached on through compression. When the vessels are small the effect on the lumina, and hence on the permeability, are considerable. Meningeal cellular invasion is always interstitial and does not give rise to exudate on the surface of the cord or brain, and it is, moreover, made up almost exclusively of mononuclear cells.

The gray matter of the cord shows lesions of the anterior and posterior horns and the commissure, but the anterior horns are as a rule more severely and widely injured than the posterior horns. The chief lesions surround the vessels and consist of a cellular infiltration

and edema of the perivascular spaces, and sometimes of hemorrhages as well. When the nerve cells and ground substance are injured, as is frequently the case, foci of similar cells occur there, and the nerve cells show degeneration and necrosis. The extent of the lesions in the gray matter varies greatly. Sometimes minute foci of injury and sometimes complete degeneration of the anterior horns occur. The infiltration of the perivascular sheaths of the vessels is continuous with that of the pia-arachnoid. The white matter of the cord holds in respect to the frequency and severity of the affection an inferior position, and the lesions when present there consist of edema, perivascular cellular infiltration, hemorrhage and necrosis of tissue. The brain shows lesions that are, however, more sparse than in the spinal cord. They correspond with cellular infiltrations of the meninges similar to but less in amount than in the cord. The intervertebral ganglia regularly are the seat of a diffuse and nodular infiltration with lymphocytic cells, which collect between the nerve cells and about the nerve fibers, both of which may be the seat of degeneration or of necrosis.

The pathogenesis of the affection is explained by the nature and distribution of the lesions. It would appear that the virus becomes implanted on the leptomeninges, especially in the region of the spinal cord and medulla, where it sets up cellular infiltrative changes that are most marked in the perivascular lymph spaces of the arteries entering the nervous tissues. The vascular lesions constitute the primary causes of the lesions of the nervous tissue, the severity of which is determined by the particular vessels affected and the intensity of the involvement. The infiltrative lesions are confined to the perivascular lymph sheath and adventitia, but still other lesions must occur in the intima of the vessels from which the edema and hemorrhage arise. The central arteries entering the anterior median fissure and supplying the anterior gray matter of the cord invariably become affected, through which the preponderance of lesions of the anterior horns is accounted for. Since the arteries supplying the posterior gray matter are less important, the lesions in the posterior cornua are slighter. The degree, therefore, of affection is determined by the richness of the arterial blood supply, whence is explained the liability of the lumbar and cervical enlargements to severe lesions. Irregularity in the branching of the central artery probably explains the common variations observed in the involvement of the two lateral halves of the body. The brain is far less commonly the seat of lesions, but it is not spared. Paralysis of the cranial nerves, and especially of the facial nerve, follows on them, but lesions also occur in parts of the brain which do not respond by paralysis. The brain injuries, like those of the cord, depend on vascular lesions.

Hence it would appear that there are good grounds for believing that a considerable part of the paralyzes, especially those that are not permanent, are the effects of temporary vascular impediments. The impediments are all outside the lumina of the vessels, which are merely reduced in caliber through pressure. Thrombi do not occur. Some of the functional disturbances are possibly thus anemic in origin; others are probably caused by slight degenerations, and still others are undoubtedly caused by focal hemorrhages and edema. All these effects may possibly be recovered from: part by resolution of the cellular vascular infiltrate and reestablishment of the lumen; part by absorption of edema and

hemorrhage, and part by restoration of the mildly degenerated nerve cells. The severer degenerative and other lesions, through which actual necrosis is produced, do not become restored. On them depend the permanent paralyzes and deformity.

THE VIRUS

The virus causing epidemic poliomyelitis has been stated to be of very minute size. It is, so far as we can now judge, one of the most minute organisms known to cause disease. This conclusion follows from the fact that in aqueous suspension, such as is secured through preparing an emulsion of the spinal cord in distilled water, it passes with great readiness and little or no loss of potency through the pores of the densest and finest porcelain filters, namely, the so-called Chamberland filter. It passes with even greater ease through the somewhat less dense Berkefeld filter. It is extremely doubtful whether the virus has actually been seen. On staining film preparations of the filtrate with mordanting dyes, preparations are secured which under the highest powers of the microscope exhibit minute points, circular or slightly oval in form, which possibly, although not certainly, represent the stained parasite. When the filtrates are examined under the dark microscope, innumerable bright dancing points, devoid of definite size and form, and not truly motile, can be discerned. That these particles represent the micro-organism of poliomyelitis cannot be affirmed, since similar particles are present in filtrates obtained from nervous and other tissues which can be viewed also as consisting of simple protein matter.

The filtrates are highly potent. Quantities as small as one one-thousandth to one one-hundredth of a cubic centimeter suffice to cause paralysis in monkeys after the usual incubation period, when injected into the brain. The virus is highly resistant to external agencies and conditions. It withstands glycerination for weeks or months very much as the virus of vaccinia or rabies does. It withstands drying over caustic potash for weeks without any or marked reduction in potency, showing a greater degree of resistance than the virus of rabies. It retains its virulence apparently unimpaired for weeks, on being kept constantly frozen at minus 2 to 4 C. It also withstands for a long time temperature slightly above the freezing point of water, in the course of which the nervous tissue containing the virus undergoes autolysis, and it has been shown to survive the growth of ordinary mould. On the other hand, it is readily injured by heating, since temperature of 45 to 50 C. maintained for half an hour suffices to render the filtrate incapable of causing paralysis. It is also readily destroyed by 1 per cent. solution of hydrogen peroxid, and by such simple disinfectants as menthol.

That the virus is a living organism must be concluded from the fact that such minute quantities of it suffice to carry infection through an indefinite series of animals. We have propagated the virus now through twenty-five generations, representing twenty-five separate series of monkeys, and as many removes from the original human material supplying it, and the activity of the virus for the monkeys has increased rather than diminished in the course, and as the result of the successive transplantations. Whether the virus has been or is to be cultivated outside of the body is still an undecided question. We early secured certain indications which led us to hope that the virus multiplied in a medium of bouillon mixed with human serum. We have, however, not succeeded

in producing paralysis by the inoculation of one of these possible cultivations. On the other hand, original virus has been observed to retain its virulence for several weeks when kept in a similar bouillon at the temperature of the thermostat.

PROGNOSIS

At the outset of the experiments we estimated that less than one-half of the monkeys that became paralyzed would, if permitted, recover more or less completely from the paralysis. Since, however, our purpose was best served at the time by sacrificing the paralyzed animals immediately on the appearance of the paralysis, they were as a rule etherized. We now believe that the deduction was erroneous and that the fatalities would have been greater than we supposed, and probably as many as three-fourths of the paralyzed animals would have succumbed to the disease. At this early period, however, a number of paralyzed animals recovered, usually, however, incompletely, retaining residue of the paralysis similar to what is observed in the spontaneous human affection. The indications now are that the virus has altered qualitatively and so increased in potency in the later generations that recoveries are hardly to be looked for. The mortality at present approaches 100 per cent., with which figure there is happily nothing in the pathology of the human affection that is comparable. In view of certain experiments of a therapeutic character which are to be mentioned, the fact of the intense activity of the virus should be borne in mind. Undoubtedly examples of the virus will be discovered which will become modified in the reverse direction and lose rather than gain in activity. At one period, indeed, in the course of propagation of each of the two viruses which we originally secured there occurred what appeared to be a sharp decrease of virulence, a change indicated by feeble effects during several passages and the final loss of power of certain strains to transmit the infection. To the circumstance that we carried the virus forward in parallel series of inoculations is to be attributed the survival and increasing activity of the strains at present in use.

INOCULATION OF OTHER ANIMALS

Repeated attempts have been made to implant the virus on other animals, but without success.¹ The animals thus employed consisted of the available warm-blooded domestic animals of this country, and included guinea-pigs, rabbits, rats, mice, dogs, cats, sheep, cows; goats, pigs, chickens, pigeons and horse. The rabbits and guinea-pigs were inoculated directly with each of the two specimens of human virus, and additional rabbits and guinea-pigs and other animals with virus derived from monkeys. In contrast with these failures is the successful employment of several species of monkeys. The greater number employed were of the species *Macacus rhesus*, but all other species of old world monkeys seem equally susceptible. These included, beside *M. rhesus*, *M. Cyonomolgus* and *nemestrinus*, *Cercocebus fuliginosus*, *Cercopithecus callitrichus*, and *Papio babuin*. Of the new world monkeys we employed two species, one belonging to the genus *Cebus* and the other including *Capuchinus*. It chanced that the larger ring-tail proved susceptible and the smaller did not, so that a question arises whether the catarrhine are not more uniformly susceptible than the platarrhine species. No instance of

the spontaneous transfer of the virus from a paralyzed to a normal monkey arose, although many opportunities for contagion in the course of our many experiments occurred. This fact does not militate against the notion of contagion in respect to the spontaneous disease in man, for the reason that the monkey is obviously under ordinary conditions and because of the possession of adequate external means of defence an insusceptible species, although once these defences are surmounted it proves less able to resist the injurious effects of the virus than human beings.

MODES OF INFECTION

We have seen that the intracerebral mode of infection is not the only successful one, and that the virus may be introduced into the body by way of the peritoneal cavity, under circumstances leading to paralysis. It has been proved that the virus, when derived from an infected monkey, may also be introduced successfully by way, not only of the peritoneum, but also by means of the general blood, the subcutis, spinal canal, large nerves and certain mucous surfaces. Thus the introduction of large quantities of virus into the stomach or duodenum does not lead to paralysis unless the motions of these organs are for a time arrested by means of opium. When peristalsis has thus been prevented infection and paralysis result in some instances after this mode of introduction of the virus. However, it would appear that none of the avenues mentioned lead so uniformly to paralysis as does the direct or intracerebral mode of inoculation into the nervous tissues. There exists, however, one mucous surface that is more readily traversed by the virus than the other avenues, excepting the brain, and that is the mucosa of the nasopharynx. If this mucous membrane is lightly scarified in an etherized animal, and the virus rubbed into the scarifications by means of a swab, infection and paralysis usually, and with few exceptions, results with promptitude. Our experience is to the effect that the tracheal mucosa and the lungs do not afford an easy point of entrance of the virus into the body, at least under conditions in which gross lesions of the superficial tissues have not been previously produced.

The facts just given concerning the several possible portals of entry of the virus of poliomyelitis into the body under conditions leading to paralysis have significance with respect to the usual portal of entry of the poison in the spontaneous infection in man. We have been led by certain theoretical considerations to view the nasopharynx as the location in the body to be regarded with special suspicion as being the portal of entry of the virus. Some of these theoretical considerations may be mentioned. Our attention was arrested by the frequently observed fact that in point of distribution epidemic poliomyelitis resembles epidemic cerebrospinal meningitis, and that the two diseases, indeed, so often presented such close similarities in this respect that they had often been confounded with each other. The chief and striking difference between them related to the seasonal prevalence, which for epidemic poliomyelitis is midsummer and for epidemic cerebrospinal meningitis late winter or early spring. The two diseases, moreover, attack by preference infants and young children, although not sparing older children and adults, and in about the same ratio. In the majority of instances a single case appears in a family or home, but often two cases, and less often three or more cases appear. The relation between the group cases in a house or locality has in respect to both

1. Krause and Meinicke, in Germany, of all those engaged in the recent investigations, alone claim to have transferred the disease to rabbits.

diseases been made out only recently, through the discovery of the rôle of the intermediate carrier of the infection.

Now it is held that the *Diplococcus intracellularis* passes into the cerebrospinal membrane by way of the lymphatic connection existing between them and the nasopharyngeal mucous membrane. None of the lower animals, not even monkeys, are so susceptible to the pathogenic effects of the *Diplococcus intracellularis* that its inoculation into the nasal mucosa suffices to set up acute meningitis. We have already seen that the virus of poliomyelitis, which is so much more active, can be introduced successfully by direct inoculation into this membrane.

The considerations thus far given show the close agreement existing between the two diseases, epidemic meningitis and epidemic poliomyelitis, in respect to the part played by the nasopharyngeal mucous membrane. Still other considerations are these: It is difficult, if not impossible, to establish in human beings the fact that the diplococcus passes from the meninges by a reverse lymph current into the nasopharynx, and yet such a migration is not only highly probable, but would most readily and satisfactorily explain the persistent intracellularis infection of these mucous membranes, which is regularly present in epidemic cerebrospinal meningitis. The case is quite different in monkeys infected with *Diplococcus intracellularis* by injection of cultures into the lumbar spinal canal, in which the migration into the nasopharynx of the diplococcus contained in leukocytes, and free also, has been followed with the microscope. It may therefore be regarded as established that this mucous membrane serves both as the site of escape from and of entrance into the meninges of the *Diplococcus intracellularis* in man. The question arises: Does this membrane serve a similar double function in respect to the virus of poliomyelitis? That it may serve for its entrance into the body we have already seen, and the experiment is readily made to determine whether or not the virus is also excreted there. The excised mucosa of monkeys recently paralyzed and killed has only to be rubbed up with quartz sand, suspended in distilled water and pressed through a porcelain filter in order to secure a fluid free from bacteria and suitable for inoculation into the brain of healthy monkeys. By employing this method we have been able to produce paralysis, and thus to prove that the mucous membrane contains the virus. The virus in the mucous membrane is not derived from the blood contained within it. It is true that the blood does contain the virus, but in such minimal quantities that an amount of two cubic centimeters may fail to cause the infection, while as much as 20 has caused typical paralysis. Moreover, we have ascertained that the organs generally do not contain the virus in such amounts as readily to convey the infection. We have failed repeatedly to secure infection from the spleen, bone marrow, liver and different groups of lymphatic glands, and in several experiments failed to develop paralysis after injection of the salivary glands, although Levaditi has reported one such successful experiment among several failures. We have failed to produce paralysis by the injection of a suspension of the mesenteric lymph nodes taken from an animal that had become paralyzed as a result of an intrastomachic injection of the virus, while we have been successful in producing paralysis with the mesenteric lymph nodes secured from a human case of poliomyelitis. That the lymphatic

glands in the monkey are capable of retaining the virus in an active state is proved by the fact that after subcutaneous inoculation of an emulsion of the spinal cord derived from a paralyzed animal, the regional lymphatic glands (axillary and inguinal) proved infectious. Again, Römer and Leiner and Wiesner have in certain instances caused paralysis by injecting into the brain emulsions of the mesenteric and of the cervical lymphatic glands taken from monkeys which became paralyzed following an intra-cerebral inoculation of the virus. It appears, therefore, that the virus may be retained for a time by certain distant organs, and especially by the lymphatic glands, which it reaches through the general circulation; but these localizations give no indication of the point of entrance into the body of the virus. The virus has thus far not been found in the excreta, that is, in the feces and urine, nor in the intestinal mucosa or bile. Since the virus is filterable it is possible to demonstrate its presence in material highly contaminated with bacteria.

We are disposed to the view that the nasal mucosa serves not only as the portal of infection but also as the path of elimination of the virus into external nature, since such elimination must occur in order that the virus be maintained alive and transmissible. It is well known that direct connections exist between the meninges and the nasal mucosa by way of the lymphatics, which pass with the filaments of the olfactory nerve through the cribriform plate. We have already alluded to the fact that the virus first becomes implanted on the leptomeninges, and this primary location of the virus is what would be especially favored by the mode of entrance of the virus just mentioned. That the early participation of the leptomeninges does not occur without certain definite corresponding alterations taking place in the cerebrospinal fluid we have been able to demonstrate. It will be recalled from the cerebrospinal fluid obtained by lumbar puncture from cases of the human spontaneous disease at different periods after the onset of paralysis, have shown only slight qualitative abnormalities. These fluids, which are clear, but may be in excess, show merely a moderate increase of the lymphocytes normally present, and no other qualitative changes. Moreover, this fluid has been shown by repeated tests to be non-infectious, or at least not capable of setting up paralysis in monkeys, even when injected into the brain. In monkeys on the other hand, in which the spinal fluid can be investigated during the incubation period of the disease, as well as after the development of paralysis, it has been shown that the reaction of the meninges to the injection of the virus occurs quickly and that at the expiration of periods of twenty-four, forty-eight or seventy-two hours, the number of cells within the fluid has progressively increased, so as to give rise to a slight opalescence of the fluid which becomes subject also to spontaneous coagulation. The fluids contain an excess of protein, as may be shown by means of Noguetti's butyric acid test. This condition of increased cells and protein is of brief duration and is succeeded by one in which the fluid is clear and non-coagulable and the protein not increased, but only the lymphocytes are more numerous than normally. This is the state of the fluid in monkeys at a period concurring with the onset of paralysis, or appearing soon after, so that there is essential agreement between the two conditions. The spinal fluid taken from monkeys when clear and limpid, does not convey the infection and produce paralysis, but when

the fluid is taken at an earlier period, at the height of the opalescence, it is capable of transmitting the disease.

Finally, the question arises whether the virus of poliomyelitis can be directly implanted on the leptomeninges, which question can be answered in the affirmative. If an active virus is introduced by lumbar puncture into the meninges, infection and paralysis may be produced. Hence it would appear as though all the theoretical conditions required to establish the nasal and meningeal route as a direct one for infection in poliomyelitis had been supplied by experiment.

It remains to add that in course of the demonstration given by these experiments, two important subsidiary problems have been elucidated: First, the pathogenesis of the affection has been rendered clear and comprehensible, and next the changes in the spinal fluid induced by the infection have been brought clearly into view as constituting criteria on which, even in human cases, an early diagnosis of the disease, preceding the onset of any meningeal or paralytic symptoms, may come to be based. What is required merely is that those physicians having access to clinical cases should perform lumbar puncture early² when poliomyelitis is suspected, and during the prevalence of an epidemic on patients presenting a series of indefinite symptoms that precede as prodromata the onset of paralysis, or themselves comprise the group-symptoms that may define the so-called abortive form of the affection.

IMMUNITY

Experiments have been conducted to determine the kinds and degrees of immunity which are produced by the inoculation of the virus of poliomyelitis. Since the literature on epidemic poliomyelitis is silent on the subject of reinfection, it can be inferred that a second attack of the disease is rarely ever suffered by one individual. Two possible reasons can be assigned for this: The first and most probable is that one attack of this disease, as is the case with some other acute general infections, tends to afford an enduring immunity, and the other, that as epidemics have in the past occurred infrequently and reappeared after long intervals, the children once affected have passed beyond the susceptible age period at the time of the next epidemic.

We have available in monkeys which have recovered from an undoubted infection, attended by paralysis, an opportunity to decide the question whether an attack of poliomyelitis protects against subsequent infection. Thus far we have subjected a number of monkeys to reinoculation into the brain at periods varying from eight days to four or five months, after the paralysis first appeared, without succeeding in reinfecting any of these animals. They were not rendered perceptibly sick by the subsequent inoculation after the one originally producing paralysis, and in no instance was recrudescence of the paralysis produced. It is interesting to note that in point of severity the first attack varied between mere tremor of the head, a partial paralysis of one limb, and complete paralysis of legs and arms. The paralysis had in some instances nearly or completely disappeared, and in others it had become reduced, but still affected all the muscles of one or two limbs. These results indi-

cate what will probably be found to be true equally of human beings, that an undoubted attack of poliomyelitis, even when unaccompanied by definite paralysis, produces a state of refractoriness in reinoculation with active virus that endures for months and probably for years, if not throughout the life of the affected individual. On the other hand, our experiments, embracing now a large number of monkeys, establish that when the virus is introduced into the brain, practically all monkeys belonging to the generally susceptible species are subject to infection, although they do not invariably succumb to the first inoculation, but may require a second injection. However, it would still appear that rare individual monkeys are highly refractory to infection, and it has also been observed that an unsuccessful inoculation of the virus does not act as a protective, but leaves the unaffected animals either with their original degree of susceptibility unimpaired, or, what further experimentation will be needed to confirm, leaves the animals possibly somewhat more disposed to a subsequent infection.

This latter point of the failure of an unsuccessful intracerebral inoculation of the virus to increase resistance does not answer the question negatively, whether by suitable means it may not be possible to develop an active immunity independently of the production of even the most trifling symptoms that might be taken to indicate an attack of poliomyelitis. We have, indeed, been successful in establishing in a certain number of monkeys a state of active immunity through a single large subcutaneous injection of the crude or modified virus, as represented by the emulsions of the spinal cord taken from recently paralyzed monkeys, or by repeated injections of gradually increased amounts of the crude virus. This mode of producing active immunity has not, up to the present, been developed into a uniformly successful and safe method, since of the treated animals some do not develop a strong immunity and others develop paralysis as a result of the treatment. The direct immunizing effect has been produced also by means of a virus somewhat modified after a long immersion in glycerin, so that it may be regarded as probable that a qualitatively modified virus, changed through the action of chemical or physical agents, or modified by biological conditions within certain hosts, can be produced, and that this altered virus will be found more appropriate than the virus of full potency for purposes of active immunization. At present the experimental basis is entirely inadequate to justify the attempt to induce active immunity as a protective measure in human beings. Monkeys thus directly immunized resist successfully the injection of large doses of virus into the brain.

It has therefore been established that an undoubted and even high degree of immunity to infection with the virus of poliomyelitis is obtainable in animals, and probably equally in human beings. The question which next arises is this: As a result of this immunity, do the body fluids acquire new properties capable of experimental demonstration, on which the immunity probably depends? In answer it can be stated that human beings and monkeys who have passed through an attack of poliomyelitis come to contain in their blood certain neutralizing principles for the virus of poliomyelitis, and that these principles are readily demonstrable by animal tests for two or more years in human beings, and that they probably persist for as great a period in monkeys. Similar principles are absent from the normal serum.

2. The earliest cellular reaction in monkeys is not purely lymphocytic but includes polymorphonuclear leukocytes which may predominate for the first period of one or two days. The earliest reaction of the meninges in human beings also is attended with polymorphonuclear excess (Wlekman and Fulton.)

They are demonstrated by bringing into contact an active filtrate containing the virus with the serum of the blood derived from animals or human beings who have recovered from poliomyelitis, or from monkeys actively immunized directly to the virus, and incubating the mixture for a period at 37° C. and determining that after this treatment the virus is no longer able to set up paralysis on being injected into the brain of normal monkeys. Furthermore, it has been shown by Netter and Levaditi that the blood of a patient who had suffered an abortive attack of poliomyelitis contained such neutralizing principles.

A pressing question could now be approached, namely, whether the immunity principles contained within the serum suffice to neutralize the virus of poliomyelitis once it is present in the body. It could be assumed that the serum of animals, as of human beings that had recovered from paralysis, would contain the immunity principles in no high state of concentration. Effort was therefore made to reinforce the degree of immunity in these monkeys by subsequent inoculations of virus, and the therapeutic experiments defined were conducted in part with this reinforced serum, and in part with the serum of directly immunized monkeys, and such serum as could be obtained from human patients. It can now be stated that if the quantity of the virus injected into the brain be not in excess of a given dose the development of paralysis can in some cases be prevented by making several injections of the serum by lumbar puncture into the subarachnoid space, while in another number of animals the onset of paralysis is much delayed. In respect to the latter point it may be stated that the period of incubation in the control animals ranged from seven to eleven days, and in some of the animals treated with the human serum the onset of paralysis was delayed until the twenty-sixth or twenty-seventh day. Moreover, infection by the nasal mucosa can also and with greater certainty be prevented by the serum injections.

The manner of making the therapeutic injections was somewhat varied, but in general may be described as follows: An intracerebral injection of the virus having been made, after the expiration of a period not exceeding twenty-four hours, the subarachnoid injections of the serum were performed on three successive days, after which, an interval of three days having been allowed to elapse, three more daily injections of serum were given. We chose the subarachnoid method of injection rather than the intravenous mode, in order that the immunity principles might be brought into the most direct relationship with the virus, and particularly in view of our conception of the pathogenesis of poliomyelitis and of the primary site of localization of the virus in the leptomeninges. We believe that as good results could not be achieved by the intravenous injection of the serum, although the immunity principles could doubtless be brought to the nervous tissues by the circulating blood, for the reason that we know that these principles are not readily if at all secreted into the subarachnoid space. Hence they would not come into relationship with the seat of the active virus at a period preceding its active proliferation and extension throughout the nervous tissues. We think it also probable that had the serum injections been resumed after another interval of rest, the last vestiges of the virus in the tissues might have been destroyed in those animals in which the incubation period was much delayed, so that the ultimate appearance of paralysis might have been entirely prevented.

We have sought to ascertain whether animals protected from infection through the employment of mixtures of virus and immune sera, or as a result of treatment by subarachnoid injections of immune sera for therapeutic purposes, exhibited an unusual degree of resistance to subsequent intracerebral injections of active virus made at periods of several weeks to four or five months after the conclusion of the original experiments. The object of these tests was to ascertain whether a permanent augmentation of the natural resistance to infection had been accomplished by the introduction of the virus under these conditions of restraint into the body. We have found that no unusual degree of resistance to subsequent intracerebral injections of active virus has resulted, which fact we believe points to the validity of the following deductions: (1) A neutralized mixture of virus and immune serum does not lead to any degree of active immunization; (2) the therapeutic action of an immune serum is associated with restraint of multiplication of the virus such as would be required to establish any grade of active immunity; (3) a simple passive immunity is either not produced at all by the serum injections, or is of brief duration or small amount.

PRODUCTION OF A SERUM

The observations on immunity which have been presented early suggested that an effort be made to produce a corresponding active immunity in some of the lower animals that might possibly become the source of a therapeutic serum. This particular phase of our studies is being actively pursued at the present time. However, several facts have already been developed. It has, for instance, been found that the horse does not readily respond even to large injections of filtrates carrying the active virus with the development of immunity principles within the blood. It is true that our experiments are restricted for the present to a single horse, the blood serum of which, after many months of treatment, had no restraining effect on the virus either *in vitro* or within the body. The rabbit and chicken would seem not to yield such immunity principles. On the other hand we have secured indications that the sheep may react more favorably. It has been found that normal sheep serum possesses a definite although slight neutralizing power for the filtered virus when mixed directly with it, and that the injection of emulsions of the spinal cord and brain of recently paralyzed monkeys into the sheep augments this property of neutralization. What remains to be determined is the degree to which this augmentation can be carried, and whether a serum can be secured that will possess therapeutic value; but should the sheep fail in this respect, the search must be continued and be made to include still other species of animals, in the hope that one will be found in which the immunity response will be greater. There are serious objections to the use of monkeys as a source of a therapeutic serum, even were one of high potency capable of being prepared in those animals. The use of human serum, derived from persons who have passed through an attack of poliomyelitis, as a therapeutic agent, would be free of certain objections attached to the use of monkey serum, but it is not very probable that such an immune serum would be found to have sufficient strength or that it could be procured with sufficient readiness to make it available for practical application. Finally, the serum treatment of poliomyelitis must at the present time be regarded as strictly in the experimental state, and it can-

not be predicted how soon or whether ever at all such a form of specific treatment of the disease will be applicable to the spontaneous epidemic disease in human beings.

SUMMARY

It may be confidently stated that the experimental study of poliomyelitis has yielded a large number of important facts relating to the spontaneous disease in man. These facts include the discovery of the nature of the virus, of many of its properties, of certain important clinical and pathological peculiarities of the disease, of the phenomena of immunity, of a mode of spontaneous infection, while they have served to establish a basis on which to develop measures of prevention, and on which to build hopes for the working out of a specific method of treatment. Moreover, the advance which has now been accomplished will make it possible to determine with accuracy whether poliomyelitis is a single clinical and pathologic entity, or a generic name covering groups of symptoms and descriptive of the effects of certain lesions of the spinal cord and brain of which epidemic poliomyelitis is merely one, but the most important variety. It is not improbable that poliomyelitis, like meningitis, may be found to arise from several independent causes, and that epidemic poliomyelitis, like epidemic meningitis, may be distinguished among the varieties by being invariably the product of a specific micro-organism. We possess already evidence to the effect that certain of the lower animals, among them poultry, the dog, and possibly the horse, are subject to poliomyelitis, due apparently in each instance to a cause peculiar to the species affected.

THE ARSENICAL TREATMENT OF SYPHILIS

JOHN B. MURPHY, M.D.
CHICAGO

Much attention has recently been paid to the arsenic treatment of syphilis and particularly to the Ehrlich-Hata preparation known as "606", i. e., the dioxo-diamidoarsenobenzol dihydrochlorid, a single injection of a proper dose of which is reported to be destructive of the *Spirochæta pallida*. The recently recorded cases show a striking uniformity in the immediate curative effects in all of the spirilloses, or diseases of spirochetic origin.

It is believed that this arsenical preparation is as destructive of the spirochetes as quinin is of the plasmodia of malaria. The spirochetes disappear entirely from the local lesion and from the blood in from four to ten hours after the injection of the remedy and the disease appears to be entirely arrested in twenty-four hours. These seem astonishing statements but they are verified by a number of able observers as Ehrlich, Hata, Wechselsmann, Alt of Uchtspring, Schreiber of Magdeburg, Iversen of Russia and others.

The chemical composition of this drug as given by Dr. Bertheim, who manufactures it in the Royal Institute for Experimental Therapeutics at Frankfurt under the directorship of Prof. Ehrlich, is $C_{12}H_{10}O_2N_2As$ and is expressed by Ehrlich in the following formula:

This arseno-benzol-dihydrochlorid preparation is a yellowish crystalline substance not unlike iodoform in appearance and must be kept in hermetically sealed vials as the drug becomes very toxic when exposed to the air. For administration it must be handled with the greatest care and exact details in the technique must be carried out.

The dose is a single injection of from 3 to 7 grains, given either intravenously or into the gluteal or pectoral muscles.

It is not yet available to the profession for general use. In a letter which I received a few days ago from Dr. C. H. McKenna of Chicago, who was kind enough to go from Paris to Frankfurt at my request, he states that he was received and treated by Prof. Ehrlich with the greatest courtesy and all the matters concerning this preparation, the treatment and results, were placed at his disposal for observation. The details for the manufacture of the drug are not given to the public; in this Prof. Ehrlich has exercised a praiseworthy caution. Placing a drug that will be in such immediate demand all over the world, and used by men who do not exercise the precaution of reading and following out in detail the directions given for its preparation and administration, is a hazardous procedure, and failure in securing the best results obtainable for the patients through this treatment would follow. The longest period that patients have been under observation after this treatment is about eleven months. Prof. Ehrlich has reports on 7,000 patients treated. In this number there were six deaths: Ehrlich himself considers that only one might justly be attributed to the treatment. This drug has been used in the treatment of syphilis in all stages from the primary chancres to the deep specific lesions of the central nervous system. It seems to have the specific property of killing the spirochete in all its abodes in the tissue, i. e., of curing syphilis in its three stages—primary, secondary and tertiary. Its most prompt action is in: (1) the syphilids and mucous patches, (2) in the gummata and, (3) in the chancre; the latter, however, is sometimes very rapidly cured. The lymphatic adenopathies speedily disappear.

It does not and should not be expected to reproduce tissues that have been destroyed by the spirochete. It will not restore destroyed columns of the cord or perforations of the palate or septum nor any other destroyed tissue. It does not produce an immediate increase in the size of the lesion by edema and swelling that was so marked in the early treatment of tuberculous lesions with tuberculin. On the contrary there is infiltration and therefore pressure on the neighboring structures. The drug relieves the shooting pain, the girdle sensation and the crises of tabes almost as a hypodermic of morphin would; and it lessens the cephalalgia of the intracranial gummata.

One of the striking factors in favor of the claims of this treatment is that the most rapid effect is produced on the external or visible lesions. The cures appear to be permanent, as less than one-half dozen relapses have been recorded and most of these were easily traceable to deficient doses or to improper administration; but the patient promptly responded to a second injection. It will be noted that this is a far better result than is obtained in the average by quinin in ague or antitoxin in diphtheria and would lead us to hope that we have really another specific remedy. Regardless of what its permanent effect in definitely curing syphilis by a single dose

may be its immediate effect places it far beyond any medicament that has so far been used in the treatment of this disease and makes one feel that every sufferer should have the advantages it affords.

It has been announced that this drug will not be given to the profession for use for a number of months, a fact which forced us to try other preparations of arsenic. The one with which I have been most familiar is the sodium cacodylate which we have been using for seven years to allay the pain of metastatic, osseous carcinoma. For this purpose I have been administering it in doses of from 3 to 6 grains by mouth and have given from 1 to 2 grains in single doses daily hypodermically, also using it for the various other purposes for which arsenic is indicated. One of its striking therapeutic effects is the rapid dissolution of the deposits in fibrinous pericarditis in children, when it is administered in doses of from 1 to 3, or even more, grains daily. Its chemical formula is $(CH_3)_2 As O Na + 3H_2O$. It appears as a

which is keeping up the irritation. The adenopathies, except those with suppurating central foci, disappear in four or five days. The mucous patches repair in from twenty-four to forty-eight hours, the advancing ulcers of the palate and posterior wall of the pharynx clear up and heal as healthy granulating wounds in from three to six days and the perforating ulcers of the palate repair in their margins leaving the perforation in a healthy condition. I have not pressed it in the tertiary lesions but will not hesitate when such cases come under observation as the toxic limitations of the drug and the line of safety in its administration are known.

Photograph 1 is from a patient, aged 17, who became infected in a cold sore on the lip from a drinking cup. The examinations for spirochetes were made at the Columbus

Fig. 1.—A chancre on the lip before treatment. Syphilis from the common drinking cup.

white amorphous powder readily soluble in water. As a solution it can be injected into the muscle without causing much discomfort. It is prepared and carried by most of the wholesale druggists in ampullas containing three-fourths of a grain and is one of the safest of the arsenical preparations for administration.

When the system becomes saturated, the patient has the typical arsenical breath, with a sense of gastric distress and loss of appetite. I have been giving it in doses of from 1 to 2 grains hypodermically into the muscles and it has a most striking effect on the syphilids, mucous patches and primary chancre. From the latter the spirochetes disappear completely in forty-eight hours, the induration is markedly reduced in twenty-four and it becomes a soft, clean ulcer in seventy-two hours. From that time on it repairs with the same speed as an aseptic sore of mechanical origin would heal in the same tissue. In other words, the sodium cacodylate seems to destroy the specific micro-organism (the spirochete)

Fig. 2.—Patient shown in Figure 1, nine days after treatment of syphilis with arsenic preparation.

Medical Laboratory and slides were preserved; the spirochetes were numerous. The patient received two injections of $\frac{1}{2}$ grain each into the pectoral muscle, twenty-four hours apart. Forty-eight hours after the primary examination (at which time only a clean soft ulcer without induration remained), numerous slides were prepared for spirochetes, both at the Columbus Laboratory and at Mercy Hospital and all were negative. The injections were continued in $\frac{1}{2}$ grain doses for eight days, then from the eighth to the twelfth day in $\frac{3}{4}$ grain doses and permanently discontinued. The patient showed none of the physiologic effects of arsenic.

Photograph 2 shows the condition of the ulcer nine days after treatment was instituted as a small abraded surface without induration and no larger than a grain of flax-seed and thirteen days from the initial treatment the ulcer was completely healed with no evidence of the disease remaining.

This case was demonstrated in all its stages to the visiting physicians at Mercy Hospital.

In a child nine months old with a papillary syphilid, a $\frac{1}{4}$ grain dose was administered into the pectoral muscle. The rash entirely disappeared in forty-eight hours. In a patient with active gastric crises, two 2-grain doses were administered into the pectoral muscle, twenty-four hours apart, followed by entire cessation of pain, while in his innumerable former attacks the pain lasted three weeks.

A perforating ulcer of the palate in the service of a colleague continued to advance in its destruction under daily injections of $\frac{1}{4}$ grain doses of mercuric bichlorid. Two injections of three-fourths of a grain each, of cacodylate of sodium, caused the gray surface to disappear and the margin of the ulcer to heal over in six days.

These incomplete reports are published merely as suggestions to practitioners who are willing to try a remedy as safe as sodium cacodylate and who have numerous cases coming under their observation, as the only syphilitic cases I encounter are those presenting surgical lesions.

I would further suggest that the primary dose should be from 2 to 4 grains, depending on the size and strength of the patient and should not be repeated within three or four days unless there are special indications for it.

I have never seen such effects produced by any form of treatment.

I have not given it by the intravenous method but I will so use it in a more dilute form, in the same size doses. Prof. Ehrlich has been kind enough to send me, through Dr. McKenna, twenty-five doses of "606" which are due in Chicago in a few days and which I shall use in control cases with sodium cacodylate.

100 State Street.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 666)

GUAIACODEINE.—Codeine - Ortho - Guaiacol - Sulphonate. Guaiacodeine is Codeine - Ortho - Guaiacol - Sulphonate $C_{15}H_{21}NO_5 \cdot C_6H_3(OH)(OCH_3)(HSO_3) \cdot 1:2:6 = C_{21}H_{25}O_6NS$, the neutral codeine salt of guaiacol sulphonic acid.

Guaiacodeine is produced by the double decomposition of a soluble salt of codeine with the potassium or barium salts of ortho-guaiacol-sulphonic acid taken in molecular quantities.

It is a white crystalline powder. Soluble in 90 parts of water, 450 parts of alcohol and 30 parts of methyl alcohol, insoluble in ether; very slightly soluble in chloroform. Very soluble in hot water.

A drop of solution of ferric chlorid added to a solution of the salt in water or alcohol produces a deep blue color, indicating the presence of ortho-guaiacol-sulphonic acid.

The salt melts between $163^\circ C.$ and $165^\circ C.$ (323.4 and $327.20^\circ F.$) to a white liquid. 0.1 Gm. dissolves in 10 Cc. concentrated sulphuric acid without color.

Theoretically, the salt contains 50.44 per cent. anhydrous codein, or 62.20 U. S. P. codeine (containing 1 molecule of water of crystallization) and 49.56 per cent. ortho-guaiacol-sulphonic acid.

Ammonia and alkalies precipitate from a concentrated solution of the salt the alkaloid, codeine, which should respond to the tests of the U. S. P. for that alkaloid.

Actions and Uses.—Those of Codeine. Since the proportion of guaiacol is small it cannot well be used to secure the action of this agent.

Manufactured by the New York Quinine and Chemical Works, New York.

U. S. patent No. 432,233. Not trademarked.

SOPHOL.—Sophol is a compound of silver and methylen-nucleinic acid, the silver being in organic ("masked") form.

It is prepared by conversion of insoluble silver compounds of methylen-nucleinic acid into soluble silver compounds by treatment with neutral salts, such as chloride of sodium. Sophol is a yellowish powder, having a metallic taste and claimed to contain silver, equivalent to not less than 20 per cent. metallic silver. Sophol is readily soluble in water, the aqueous solution having a faint alkaline reaction; it does not give a precipitate on the addition of dilute solution of sodium hydroxide or of sodium chloride; it is insoluble in ether and alcohol.

If 0.3 Gm. sophol is heated in a test-tube decomposition occurs with the development of brownish-red pungent vapors. If the ash is treated with dilute nitric acid, the solution filtered, a white cheesy precipitate is formed on addition of hydrochloric acid, which dissolves in ammonia water.

If 0.5 Gm. sophol is boiled with 5 Cc. of sodium hydroxide solution, the latter assumes a black color with the development of a formaldehyde odor.

If 0.1 Gm. sophol is heated with 3 Cc. nitric acid, a dirty yellow precipitate is formed, disappearing on addition of an excess of ammonia water with the formation of an orange colored solution.

A solution of 0.5 Gm. sophol in 10 Cc. water should have a faintly alkaline reaction and should not at once become turbid on the addition of sodium chloride solution.

If 1.0 Gm. sophol is shaken with 10 Cc. of alcohol and filtered, the filtrate should not be changed on addition of hydrochloric acid.

Actions and Uses.—It is said to act as a germicide and to be free from irritating effects in the solutions ordinarily employed.

It is said to be especially useful for the prevention and treatment of ophthalmia neonatorum and may be employed in other eye affections and for the general indications of the silver salts.

Dosage.—Sophol may be applied in from 2 to 5 per cent. solutions.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 852,545. U. S. trademark No. 62,900.

PHARMACEUTICAL PREPARATIONS ACCEPTED FOR N. N. R.

The following dosage forms of accepted proprietary articles have been accepted for N. N. R.:

Adrin Inhalant Comp.—Epinephrine Inhalant Comp., Mulford.

—Each 100 Cc. contains epinephrine (as hydrochloride), 0.1 Gm. (7/16 of a grain in a fluidounce), camphor, 0.3 Gm. (1 1/4 grains in a fluidounce), menthol, 0.22 Gm. (1 grain in a fluidounce), thymol, 0.043 Gm. (1/5 of a grain in a fluidounce), oil of eucalyptus, 0.22 Gm. (1 minim in a fluidounce), and hydrastine, 0.0053 Gm. (1/40 of a grain in a fluidounce), oil of wintergreen, 0.99 (4.5 minims in a fluidounce). The solvent is a mixture of castor and cotton seed oils, together with 10 per cent. absolute alcohol by volume.

Adrin Troches.—Troches of Epinephrine—Mulford—each troche contains epinephrine, 0.000093 Gm. (1/700 grain), menthol, 0.0013 Gm. (1/50 grain), benzoic acid, 0.0027 Gm. (1/25 grain), oil of gaultheria, 0.0034 Gm. (1/20 grain), and eucalyptol, 0.0013 Gm. (1/50 grain). The base is sugar with a small amount powdered acacia.

Frivable Tablets Protan. 2 1/2 grains.—Each tablet contains protan, 0.16 Gm. (2 1/4 grains).

Frivable Tablets, Protan. 5 grains.—Each tablet contains protan, 0.32 Gm. (5 grains).

Frivable Tablets Protan. 7 1/2 grains.—Each tablet contains protan, 0.48 Gm. (7 1/2 grains).

ARTICLES ACCEPTED FOR N. N. R. APPENDIX

Reinschild Chemical Co., New York.

Extractum Chinæ Nanning.—A liquid extract of red cinchona said to contain cinchona alkaloids 5 per cent., cinchona tannins 7 1/2-10 per cent., glycerine 30 per cent., water 55-57 1/2 per cent.

Dose.—1 to 1.25 Gm. (15 to 20 minims) three times a day.

(To be continued)

Therapeutics

VACCINE THERAPY

Although every month, almost, changes the status of treatment with vaccines, and although methods of preparation and the strength of the solutions injected are almost as frequently modified, still one should keep up with the times and know the exact scientific belief in regard to the value and utility of vaccinations. Hence it is with pleasure that one reads the conservative, terse, and scientific article of Dr. Wilder Tileston, of New Haven (*Boston Med. and Surg. Jour.*, March 24, 1910).

Immunity is a variable condition, varying not only with the individual, but with the bacterium. Natural immunity occurs for a shorter or greater length of time after a person has had an infection. Artificial immunity to a given germ is caused in two ways: first, by inoculation with non-fatal doses of this bacterium, "active immunization;" second, by the inoculation of an antiserum, a serum which develops in the blood of a man or animal who has become more or less tolerant to a given germ. Injections of this serum into a subject susceptible to the germ, causing him to be more or less immune, is called "passive immunization." Tileston says, "There is a wide difference between the use of the various anti-sera and the injection of bacterial vaccines; the former are chiefly employed for their direct action on the bacteria or their toxins, the latter to stimulate the formation of protective bodies.

"These latter substances, or antibodies as they are often called, are found in the blood serum and act in various ways; the bacteriolysins destroy the bacteria, the antitoxins neutralize the bacterial poisons, the agglutinins bring about a clumping of the organisms, and, last but not least, the opsonins act on the bacteria in such a way that they can be taken in by the polynuclear leucocytes, a process known as phagocytosis."

There is always a certain amount of opsonin, the stimulant to polymorphonuclear activity, in the blood serum. Probably there are various kinds of opsonins to aid in the fight against the varying kinds of bacteria, and Wright has shown by laboratory methods that the amount of opsonin varies at different times, and especially varies during the progress of an infection. This is termed the opsonic index. This opsonic index may be increased by well-timed inoculations with the germ that is causing the disease. Scientifically the amount of the dose and the right time to administer it can only be determined by a prolonged laboratory examination of the patient's blood serum. This process, however, is too tedious, and is so easily subject to error, that it is not practical in general medicine. There can be no question that the inoculation of too large doses cause harm. This has been thoroughly proved in the use of tuberculin. On the other hand, Wright has shown that too small doses are of no value in raising the opsonic index. The clinical deduction is to begin with very small doses and carefully watch the fever and prostration reaction. If there is fever to amount to anything and much prostration, the dose was too large; if there is no indication of action from the injection, the dose was too small.

Pasteur showed in 1880 that chicken cholera could be prevented by vaccination of fowls with this organism, and later that this principle would apply to infections of other animals. In 1894 Pasteur and Haffkine demonstrated that human beings could be inoculated against cholera and become immune for some time. Over 100,000 persons were inoculated against cholera in

India. The number of inoculated persons attacked by the disease was one-tenth that of those who were not so inoculated, but it was found that if the disease did attack an inoculated individual the course of the disease was just as severe as in the non-inoculated. The protection against cholera, then, was positively demonstrated. It has also been shown that inoculations against the bubonic plague has caused the mortality to be ten times less than in the non-inoculated. The protective influence of these injections develops in twenty-four hours, and immunity has been found to last several years.

Both in England and Germany protective inoculations against typhoid fever have been demonstrated to be of value. The protection in some instances has been found to last four years. For several weeks there occurs what has been termed the negative phase of the protection during which period the individual is more susceptible to typhoid infection; therefore if individuals are to be exposed to typhoid fever or must go to typhoid regions or where they are likely to become infected with typhoid, a protective injection should be given a month before. Individuals who have contracted typhoid fever after a protective injection of several weeks before have had the disease very mildly and the mortality is much diminished. As Tileston says, it seems proved that soldiers going to regions of poor sanitation should receive protective injections against typhoid. Also, nurses and ward tenders should be protected against typhoid.

Shiga believes that protective inoculations against bacillary dysentery do not prevent the disease but reduce the mortality when the disease occurs.

Some investigators believe that vaccination against secondary infections after operations under conditions, or in regions of the body in which infection will almost surely occur, is advisable. Such protective injections have been made with the *Staphylococcus aureus* and *Streptococcus*, and with the *Bacillus coli* if the operation was on the alimentary tract. It is still a question whether such injections are advisable.

In local infections without general symptoms and with the localized infection or suppuration walled off from the rest of the body by the protective powers of the blood and tissues, but not tending to heal or to be absorbed, injections to increase the opsonic power of the blood have proved of the greatest value. The protective exudate around these localized infections, as stated by Tileston, "become poor in opsonins, owing to the absorption of these substances by the bacteria; phagocytosis is at a standstill and the bacteria are free to multiply. Add to this, in the case of abscesses the tryptic substances set free by the disintegrating leucocytes, with their deleterious action on the tissues, and we have a combination of conditions unfavorable to cure." We hasten cure by evacuating the pus and draining the region, and by stimulating the constructive powers of the body by giving stimulating drugs and pushing nutrition.

A still greater aid to hasten cure seems to be a vaccination with a culture grown from the particular germ of infection; in other words an autogenous vaccination. While so-called stock vaccinations, vaccination with stock cultures of the type of germ of the infection are of some value, the various strains, especially of a pus producing germ, vary so much, and, evidently, vary so much in the kind of opsonins that is needed to eradicate them, that it has been found that vaccination with cultures from the germ that is infecting the individual is of much greater value. Such vaccinations cause increased hyperemia around the localized disease and the increased cir-

culuation thus caused is another aid in eradicating the infection. This is the reason that the Bier hyperemic treatment of localized inflammation and infection becomes of value. In other words, the opsonins are increased and the phagocytosis more active and the eradication of the infection goes on more rapidly, if the circulation in the diseased region is stimulated. These truths are especially demonstrable in lupus where tuberculin tends to cure the ulcerative type, but when the lupus is of the dry, scaly variety it is necessary for success to combine with the tuberculin injections the use of the x-ray to cause local hyperemia.

This vaccination treatment to aid the production of necessary opsonins in the blood will, when generally adopted, make repeated and recurrent furunculosis and carbuncles rapidly amenable to cure. Slight incisions to evacuate the pus and dead tissue are necessary, but as Tileston says, extensive surgical measures will be unnecessary, if the patient is vaccinated with an autogenous vaccine.

Vaccinations in pustulent acne are rather unsatisfactory. The same is true of erysipelas.

Septic infections should certainly be vaccinated with stock vaccine and then as soon as an autogenous vaccine can be developed it should be used. The pneumococcus vaccine seems to be of most value when the pneumococcus has attacked other parts of the body than the lung, as in pneumococcic empyema or in a pneumococcic joint inflammation.

It seems now to have been sufficiently demonstrated that gonococcus vaccine is very valuable when the gonococcus has invaded joints, and especially valuable where the inflammation has been prolonged and become almost chronic. In acute infections it is of much less value. As supposable from what is known of the lack of protection or immunity after one attack of gonorrhea, the immunity from injections also does not last long. In gonorrheal urethritis, acute and chronic, in gonorrheal prostatitis and epididymitis vaccination has not been shown to be of much value. In gonorrheal vulvovaginitis of children Tileston thinks this vaccine aids recovery more than most other treatments, but still is not very satisfactory.

A number of colon bacillus infections, especially when this germ has infected the pelvis of the kidney and the bladder, have seemed to have been benefited by vaccination with this germ.

The value of tuberculin in tuberculosis, in properly selected cases, seems to be now unquestionable. Its curative value is demonstrated in tubercular inflammations in the eye, in the larynx, and in many instances in the lungs. It is yet to be demonstrated that it should always be used in tuberculosis of the lungs. There is no question that it should be exceedingly carefully used in all early stages of tuberculosis, especially in tuberculosis of the lungs. It is very pleasing to note that in tuberculous lymph nodes, especially of the neck, tuberculin injections are shown to be exceedingly valuable as preventing the necessity of severe surgical procedures and the production of very unsightly scars to last the rest of the individual's life, and to prevent the removal of the chains of glands, which, when removed, means the removal of so many guards against entrance of germs to more susceptible structures, especially the lungs. If a tuberculous gland has become an abscess, the pus must of course be evacuated, through a small incision or even aspirated, and the tuberculin treatment begun. If there is caseation, cheesy masses must be removed surgically, but it would seem unjustifiable from the records to do gross

surgery on the neck until tuberculin treatment had been proved not to cause resolution of the enlarged glands.

A tuberculous joint and tuberculous structures in the region of joints should be placed at rest, the patient given the benefit of fresh air, and tuberculin injections used, and many times operation will be unnecessary.

It has not yet been shown that tuberculin can be depended on positively to cure a tuberculous kidney, hence if it has been shown that one kidney is perfectly healthy, the diseased kidney should be removed; but if both kidneys are affected with tuberculosis, or if the other kidney is found not to be perfect in its function, tuberculin injections still offer a possibility of recovery.

If tuberculosis has generalized, in an adult, in the intestines, tuberculin is really of value. On the other hand, if the disease of a tuberculous patient, under proper treatment, seems to be at a standstill, small injections of tuberculin often stimulate the ability to combat the disease and cause the lesions to heal. It seems from the results of some investigators that infantile tuberculosis may be healed by tuberculin injections.

As has been previously stated in this department, tuberculin injections should not be given without some experience and a great deal of study of the subject. Therefore, it is not the object of this abstract to discuss either the method or the dosage of tuberculin, but to show how far the success of the treatment has advanced.

A vaccine has been prepared from a bacillus supposed to be the cause of whooping-cough, and some investigators have thought they obtained benefit from such injections. The same is true of pyorrhea alveolaris; but these are still subjects for investigation.

Vaccination in pneumonia has given in some instances a better prognosis and a diminished mortality, and sometimes seems to hasten the crisis. The best results are doubtless obtained from an autogenous vaccine.

Vaccines during the course of typhoid fever seem to be of little if any value.

Tileston quotes the following doses for vaccines:

From 100 to 1,000 millions	staphylococci.
From 5 to 200 millions	streptococci.
From 10 to 200 millions	pneumococci.
From 5 to 500 millions	gonococci.
From 10 to 200 millions	colon bacilli.
From 1-10,000 to 1-500 mgm.	tuberculin T. R.

A marked change for the worse one or two days after injection shows that a dose was too large and should be reduced. A temporary improvement soon followed by a relapse shows need for a larger dose. Naturally, debilitated persons and young children should receive smaller doses than the stronger and adults. Children, however, tolerate tuberculin pretty well. The frequency of the dose depends largely on the reaction, generally acute infections requiring smaller doses at short intervals, and chronic conditions larger doses at longer intervals, from four days to two weeks. The beginning dose should generally be quite small and then the dose rapidly or slowly increased, depending on the reaction. Tileston says "for general infections the doses are smaller than the above; of the streptococcus 5 to 25; of the pneumococcus 20 to 50; of the gonococcus 5 to 100; and of the colon bacillus 10 to 50 millions." He well decries the use of mixtures of various bacteria hoping that some particular germ of this mixture will fight some particular germ in the body. This is much like the old "shot-gun prescriptions." It certainly seems inadvisable to inject a germ into a patient to help him fight against something that he has not got.

HABITAT OF TYPHOID BACILLI IN CARRIERS

Although the recognition of the importance of "carriers" in the transmission of infectious diseases was surprisingly and seriously tardy, yet, now that this source of infection has come to be appreciated, the advance in our knowledge of the subject has been rapid. We have learned that not only are diphtheria and typhoid frequently spread in this way by apparently healthy individuals, but that meningococcus infections, and probably several other diseases, are perpetuated in endemic or epidemic form by carriers who either may have had the disease and recovered, or are hosts of an organism pathogenic to others but to which they themselves are immune. It is in connection with typhoid and paratyphoid that infection by bacillus-carriers has been especially considered within the last few years, and with these diseases it has been believed that the habitat of the infecting organisms is chiefly the gall-bladder, and their avenue of escape the bowels. It has also been recognized that in some cases the bacilli are discharged in the urine for many years after convalescence from typhoid, and in these cases the place in which the bacilli are multiplying and from which they are discharged into the urine is often a problem. In some instances a definite cystitis, pyelitis or nephritis explains the persistence of the organisms, but in other cases there is no evidence of such lesions and the administration of urinary antiseptics may fail to remove the bacilli from the urine.

An explanation of these cases has been advanced by Marchildon,¹ who has found, in two fatal cases of typhoid, infection of the seminal vesicles and prostate. In view of the known tendency of infections of these organs to assume a chronic character and to discharge the causative organisms in the urine, there is reason to suspect that typhoid convalescents may harbor typhoid bacilli in this way; this should be especially suspected and investigated in patients with long-continued bacilluria in whom the micro-organisms disappear under treatment and then reappear at a later date.

Support to this suggestion of Marchildon's is furnished by comparative pathology through the recent investigations of Huet.² It seems that it has been frequently observed that male animals used for breeding purposes have transmitted to the females diseases from which the males had long since recovered. This has been reported several times with the influenza of horses, which is of particular interest since this disease, like typhoid in man, is not ordinarily localized in the generative organs. Huet examined the seminal vesicles of domestic animals, some of which animals were normal, while some had been infected experimentally with different organisms at varying periods of time before death, and found that frequently pathogenic bacteria can be found in the vesicles of perfectly healthy animals, while animals dying of experimental infections usually show seminal infection. Occasionally, in animals which had recovered from the infection, the germs could be demonstrated in the contents of the seminal vesicles even when the other viscera were quite sterile. From these several observations it is highly probable that typhoid bacilli frequently enter the contents of the seminal vesicles and prostate during typhoid fever, and that they may occasionally set up a chronic infection which can become a source of typhoid bacilluria of grave sanitary danger. Such localization of typhoid bacilli in the male generative organs can scarcely be a common cause of contagion, however, since about four-fifths of all known bacillus-carriers have been women, according to the review of Simonds;³ nevertheless it is well that this source of danger has been pointed out, in order that it may not be overlooked in the search for typhoid carriers.

STUDIES IN ANAPHYLAXIS

The study of the phenomena of anaphylaxis has received considerable attention from investigators during the past year, and though sufficient time has not elapsed for the confirmation of all conclusions reached, much progress has been made in the knowledge of the subject. The later experiments and studies of Anderson and Frost⁴ on the antibody concerned in the production of the phenomena of anaphylaxis lead them to conclude that this substance is quantitatively neutralized by the specific antigen; that it largely disappears from the serum of guinea-pigs during anaphylactic shock, but can be demonstrated in increased quantities in the serum of immune animals some time after recovery from such shock, and that it can be transferred to normal animals in such a way as to sensitize them against the antigen. To the antibody they give the name of "allergin," which they hope will be adopted as the

4. Bull. 64, Hyg. Lab. U. S. P. H. and M.-H. S., June, 1910. This is the fifth bulletin of the Hygienic Laboratory on anaphylaxis.

1. Marchildon, J. W.: Typhoid Spermatocystitis and Prostatitis, and Their Relation to Chronic Typhoid Bacilluria, *Amer. Jour. Med. Sc.*, 1910, cxi, 74.

regular designation of this substance. They summarize their views on the whole subject of anaphylaxis as follows:

Anaphylaxis is a step toward immunity, which is conceived as an increased capacity of the organism for safely and rapidly eliminating a specific antigen protein. It is remarkable among immunity reactions chiefly in the fact that (in the guinea-pig especially) the stage of hypersusceptibility is strikingly constant, well-defined and of long duration.

Immunity is a state of relative insusceptibility, characterized by an increase in the amount of free anaphylactic antibody. Whether the insusceptibility of an immune guinea-pig is due to this excess of free anaphylactic antibody, to the formation of another free antibody, or to specific changes in the somatic cells is an open question.

Hypersusceptibility to a foreign protein consists in an increase in the normal power of assimilating this protein, especially an increase in the rapidity of the reaction. This is due to the formation of a specific antibody (or antibodies) demonstrable in somatic tissues (smooth muscle) and in the serum of sensitive guinea-pigs. The action of this antibody on its antigen is quantitative and is probably primarily proteolytic.

Anaphylactic shock is due to disturbance of metabolic activities of vital cells rather than to the specific (permanent) intoxication of cells.

Antianaphylaxis is a state of absolute insusceptibility, due to saturation of the specific combining receptors. It is a temporary condition and passes gradually into the condition of relative insusceptibility known as immunity proper.

The interest in anaphylaxis lies in its relation to immunity. In the present development and understanding of the subject it has not been proved that effective practical immunity to particular diseases can be produced in this way without causing more or less serious damage to the host in other directions. The principle is tremendously suggestive, however, and may lead to the most important results. It points to possible valuable discoveries in the treatment of tumors, to a better understanding of the phenomena of asthma, and to the fact that the action of tuberculin involves the principle of anaphylaxis.

THE LESSON OF POLIOMYELITIS

The increasing prevalence of anterior poliomyelitis has made it one of our most important diseases. On account of its insidious nature and its distressing—often permanently disabling—sequelæ, blighting, as it does, the lives of the young, it has especially appealed to human sympathy and has stimulated efforts along scientific lines to solve its difficult problems. No more forceful demonstration of the modern method of studying disease has been afforded than is found in the instance of

epidemic poliomyelitis. Clinicians have made an intensive, systematic study of the disease and its epidemiology in the numerous localities in which it has appeared; but a still greater study is that which has taken place in the laboratories.

While it is true that some of the more important features have not yet been worked out—the causative organism, the question of immunity and a prophylactic or curative serum or vaccine—yet the laboratory study of the disease has progressed with such sure, swift steps that the early attainment of fairly complete knowledge of the disease is promising.

Most important among the studies have been those of Flexner and Lewis and their co-workers. The short notes published from time to time in *THE JOURNAL*, detailing the steps in the progress made in their experimental studies, and the final fuller paper of Flexner in this issue, giving a complete statement of the findings thus far made, the conclusions that may be drawn from them and outlining the requirements of the future study of the affection, constitute a striking record of results to be attained by persistent, systematic investigation in well equipped laboratories with every facility at command. This work has determined the pathogenesis, though not identifying the causative organism; has indicated the possibility of early diagnosis by examination of the spinal fluid, the probability of the establishment of an active immunity by injections of the attenuated virus; has established the presence of neutralizing principles in the blood of human beings as well as in that of monkeys following an attack of the disease, and has given some promise of the production of an immunizing serum in certain of the lower animals. All of which points to the early final solution of the problem.

It also is another instance of the absolute justification of animal experimentation in the study of the diseases of human beings.

Current Comment

NATIONAL CONSERVATION CONGRESS AND A DEPARTMENT OF HEALTH

The National Conservation Congress, recently in session in St. Paul, adopted a platform setting forth the views of the delegates as to the duty of the federal and state governments in conserving the natural and vital resources of the nation. One of the planks, unanimously adopted by the committee on resolutions and later by the convention itself, endorsed in no uncertain terms the establishment of a department of health. This plank read: "We also recommend that in order to make better provision for preserving the health of the nation a department of public health be established by the national government." This declaration was adopted in spite of a large amount of carefully stimulated (and simulated) opposition. The plank was introduced before the com-

mittee on resolutions by a delegate from Pennsylvania. As soon as it was known that there was likelihood of its adoption telegrams from all over the country began to pour in on the members of the committee on resolutions, requesting, urging and demanding that no action be taken on this subject. On Thursday morning, when the delegates assembled in the auditorium, there was found on each seat a marked copy of the *Pioneer Press* containing a full length, two column "appeal" (otherwise known as advertising-matter) from the National League for Medical Freedom, reiterating previously made statements regarding "political doctors," "medical trust," "interference with liberty" and other stock bugbears. But, as a reporter for the *Pioneer Press* said, "the delegates smiled." The men composing the convention, who had been sent to St. Paul to represent the interests of the people and not the people of the interests, who had been able to detect the cloven hoof of monopoly under the specious plea for "state rights" which had been made in the opening days of the convention, were not slow to understand who and what were the influences back of the objections to governmental action for the saving of life. "The delegates smiled" when they received the telegrams, when they adopted the resolution of the committee and when the unanimous vote of the convention approved the platform. It was the sound judgment and common sense of the average American citizen which led the delegates to realize that health and life are important and that the only men who oppose any means by which life can be saved are those who have a selfish and mercenary interest in perpetuating present conditions.

THE SEROTHERAPY OF ASIATIC CHOLERA

-As is well known, the serotherapy of cholera has thus far not been markedly successful. In the Russian epidemic of 1908-9 three kinds of antiendotoxic and two of antitoxic serum were used. Stühlern¹ ascribes greater potency to the former, particularly when administered in large quantities by the combined intravenous and subcutaneous method supplemented with copious saline infusion. It must be admitted that even the serum giving the best results (Schurupow's) did not lower the mortality rate below 30 per cent. One of the recent reports on an anticholera serum is that by Salimbeni,² who conducted his experiments, for so they must properly be called, in St. Petersburg during the serious outbreak in that city in the summer and autumn of 1908. The method used was that proposed as long ago as 1896 by Roux, Metchnikoff and Salimbeni himself and recently described in detail by the latter writer.³ The serum used in St. Petersburg was obtained from two horses "strongly immunized against the soluble cholera toxin," and 0.025 c.c. is said to have neutralized *in vitro* in 10 minutes twice the minimum lethal dose of cholera toxin for a guinea-pig of 250 grams. The article cited deals with only 42 cases, so that very general conclusions are hardly warranted. In this number, the mor-

talidity rate was about 24 per cent. The protocols of the individual cases indicate that no harm resulted from the serum injection (50 to 150 c.c.), and that in some cases benefit may have been produced. However, even under the most favorable interpretation, the curative power of the anticholera serum used in these observations does not seem very high.

SANITARY WORK IN BRAZIL: GOOD HEALTH A COMMERCIAL ASSET

Vice-Consul-General Slechta, of Rio de Janeiro, reports regarding the work of Dr. Oswald Cruz, to whose transformation of Rio de Janeiro from one of the most unhealthful to one of the most healthful of cities several references have appeared in *THE JOURNAL*. Dr. Cruz is now in the Amazon Valley carrying on a campaign against yellow fever, malaria and other diseases which have prevented the extension of commerce and industry in that region. The first work undertaken was in connection with the railroad being built around the falls of the Madeira and Mamore rivers, 500 miles south of the export rubber market of Manaus. The American contractors who are constructing this road have encountered great difficulties owing to yellow fever, malaria, beriberi and other diseases and have finally entered into a contract with Dr. Cruz to direct the work of sanitation along the right of way of the railroad and to stamp out diseases so far as possible in order to permit the completion of the railroad. It is also planned to undertake the suppression of yellow fever at the port of Para at the mouth of the Amazon, as well as at Manaus. The prevalence of yellow fever and malaria in the Amazon Valley has been one of the chief handicaps in the extension of trade and commerce and especially in the development of the rubber business. It is a sad commentary on human nature but an increasingly apparent fact that good health and the suppression of disease are attracting far greater attention now because their bearing on commerce and business is becoming evident. So long as it was merely a question of saving human lives the public remained apathetic. Now that good health and hygienic conditions are becoming recognized as business assets, we may look for increased interest and activity in the prevention of disease.

"VIVISECTION" NO MORE PAINFUL THAN TAKING CASTOR OIL

The statement has recently appeared in a number of newspapers that the Bureau of Animal Industry at Washington had entered into arrangements with the district commissioners of Washington, whereby the commissioners were to turn over to the bureau for experimentation the stray dogs of the city. In a number of cases, these statements were accompanied with comments expressing horror at the cruelty of the "experimenters" and "vivisectionists" employed in the government service and protesting against the Department of Agriculture entering on a career of wholesale vivisection. A more sensible method of procedure is shown in the following from *Our Dumb Animals*, the official organ of the Massa-

1. Med. Klinik, 1909, v, 1452; *THE JOURNAL*, Nov. 6, 1909, p. 1604.
2. Ann. de l'Inst. Pasteur, 1910, xxiv, 34.
3. Ann. de l'Inst. Pasteur, 1908, xxiii.

chusetts Society for the Prevention of Cruelty to Animals, a publication which can hardly be regarded as prejudiced in favor of animal experimentation:

A wide-spread indignation among humane people, and particularly among the foes of vivisection, has been aroused by newspaper reports to the effect that the Bureau of Animal Industry has entered into arrangements with the district commissioners of Washington whereby the former was to have turned over to it for experimentation the stray dogs of the capital city. Knowing how little confidence is to be placed in the ordinary newspaper report, we wrote at once to the department for the facts. Our readers will be interested in the reply which we summarize as briefly as possible:

There is a disease known as "gid" from the symptoms of giddiness which it commonly produces in affected animals. It is transmissible from dogs to ruminants only. Of the domestic animals, sheep are most often the sufferers from this trouble. The disease is prevalent in the northern half of Montana. It is generally traceable to imported sheep or imported sheep-dogs. The most effectual way to eradicate this disease is to keep dogs, particularly sheep-dogs, free from tapeworms, the multitudinous eggs of which scattered about the pastures are the immediate source from which sheep, cattle and other ruminants become infected with the disease.

The Secretary of the Department of Agriculture writes that arrangements were made whereby the district commissioners of Washington should supply a number of unclaimed dogs from the pound for use in investigations connected with this disease. He states, however, that nothing more painful can happen to these dogs than would be experienced in taking a dose of castor oil. The desire is to find the best vermifuge, that is the one most efficacious and suitable for the expulsion of tapeworms.

We commend the caution shown by the editors of *Our Dumb Animals* in going to headquarters for an authoritative statement instead of relying on garbled and misleading newspaper items. If all the advocates of humane treatment for animals would follow the same course with regard to their statements and "statistics," much of the misconception which surrounds this question would be dissipated. As has been shown repeatedly, there is an exceedingly small amount of suffering connected with "vivisection": most of the "evidence" submitted by the opponents of animal experimentation is the result of misconception or a heated imagination.

SUGGESTION AND NOSTRUMS

One of the cruellest and most despicable phases of the "patent medicine" business is the studied effort made by nostrum exploiters to frighten their victims into the belief that they are suffering from some more or less serious disease. Not content with the sale of their preparations to those who have—or who believe they have—one of the many diseases for which the products are recommended, the "patent medicine" venders strive to create an artificial demand for their stuff by working on the imagination of the healthy and persuading them that they are sick. The scheme is an old one but none the less disreputable. One of the more recent modifications of this trick is the "gall-stone remedy" fake, a type of which is described in the Pharmacology department of this issue. Hundreds and possibly thousands of people have been humbugged by this scheme and, unless physicians enlighten the public, thousands more will be. Once let people know that they are asked to pay a dollar for a few cents' worth of olive oil and a couple of Seidlitz powders and the number of cases of (imaginary) cholelithiasis will be reduced.

Medical News

DISTRICT OF COLUMBIA

Higher Requirements.—Word from Dr. William C. McNeill, secretary of Howard University School of Medicine, states that, beginning this fall, one year of collegiate work, including the subjects: physics, chemistry and biology, and a reading knowledge of German or French, will be required for admission. The name of this college was omitted from the list published in our Educational Number of those schools which were requiring one year of collegiate work for admission.

Personal.—Dr. MacPherson Crichton, Washington, appeared before the Justice of the Police, August 29, for a preliminary hearing on the charge of manslaughter, alleged to have been due to an automobile owned and driven by Dr. Crichton. A bond of \$5,000 was given at the time for his appearance. It is said that he has been arraigned three times for unlawful automobiling and was held on bonds of \$150 in each case for his appearance September 4.—Dr. Charles S. White, Washington, has been appointed deputy coroner by the District Commissioners, vice Dr. Larkin W. Glazebrook, resigned to become chief surgeon of the Washington Railway and Electric Company.

Studying Poliomyelitis.—The Medical Association of the District of Columbia at its meeting, August 23, 1910, appointed a committee to investigate and report on the status of epidemic anterior poliomyelitis in Washington. The disease has been prevalent in Washington during the summer, as it has in many other places, and this action is in line with that taken in other localities, to obtain all the information possible on its etiology, epidemiology, course, diagnosis, etc. The committee desires complete records of all cases occurring in the district in both private and hospital practice and to that end has prepared and sent out a circular letter explaining the object of the inquiry and requesting the cooperation of physicians in making the investigation complete. A question blank covering all angles of the disease accompanies the letter. The points to be covered in the inquiry are as follows:

1. Whether the secretions of the nose and throat are capable of carrying the disease, and, if so, when the period of infectivity begins and when it ends.
2. Whether it is possible by any method to recognize the disease with certainty before the onset of paralysis, and, if so, how.
3. Whether it is possible by any method to identify abortive or atypical cases, and "carriers," if "carriers" exist, who present no clinical symptoms.
4. Whether any intermediate host, such as insects or domestic animals, may be responsible for the transmission of the disease.

ILLINOIS

Chicago

Personal.—Dr. Mortimer Frank has been appointed a member of the Chicago Public Library Board.—Drs. G. Payll Marquis and William L. Baum have gone to Europe.

Health League Organized.—At a meeting held September 14 in Hull House theatre, the Chicago Health League, an organization to join all forces of the city, individual and municipal, in a cooperative effort for better sanitary living conditions, was formed. Dr. H. Cohen presided, the sanction of the department of health was given to the enterprise, and Health Commissioner Evans stated that an organization embodying all the functions of the numerous associations would tend to make more perfect sanitary conditions.

INDIANA

Public Comfort Station Dedicated.—The first public comfort station in the state was dedicated in Indianapolis at the corner of Wabash and Illinois streets.

Fraud Order Entered.—The post office department is said to have entered a fraud order against Dr. Jacob W. Coblenz and the Compound Oxygen Company, Fort Wayne, who are alleged to have been exploiting a mixture called "Compound Oxygen."

Addition to Hospital.—Work has been begun on a large addition to the Methodist Episcopal Hospital, Indianapolis. The building will be four stories in height. Each floor will have a sun parlor. A roof garden will be added and 72 additional patients can be accommodated in the institution.

Association of Charities Meeting.—At the recent meeting of the State Association of Charities, Indianapolis was chosen as the next meeting place. Prof. U. G. Weatherby, of Indiana University, was elected president; Mrs. Wallace B. Campbell,

Anderson, secretary, and Dr. Samuel E. Smith superintendent of the Eastern Hospital for the Insane, Richmond, chairman of the executive committee. One of the chief topics discussed was that of farm colonies for the insane.

Antituberculosis Work of the Red Cross.—The Indiana State Organization of the Red Cross gave a demonstration at the State Fair at Indianapolis last week of the work being done for the prevention and treatment of tuberculosis. A cottage was erected on the fair grounds and the latest methods of prevention and treatment of tuberculosis were demonstrated.

Tuberculosis Colony to be Established.—The St. Joseph County Hospital has appropriated \$5,000 for the establishment of a detention hospital and \$3,500 for a permanent fresh air colony for tuberculosis.

Personal.—Dr. Joel M. Partridge, South Bend, is reported to be seriously ill in Epworth Hospital, South Bend. —Dr. E. S. Waymire, a member of the house staff of the Methodist Episcopal Hospital, has been appointed house surgeon of the Wabash Railroad Hospital, Peru. —Drs. Geo. D. Kahlo, French Lick, and Chauncey W. Dowden, West Baden, have returned from Europe. —Dr. Earl Green, Muncie, has been elected Captain in the Medical Corps, Indiana National Guard. —Dr. Claude Lenox, Tell City, has gone to the Island of Molokai, to make a clinical study of leprosy.

KANSAS

Personal.—Dr. Elmer E. Haynes, Lewis, has been elected director for the Southwestern Division of the North American Esperanto Association. —Dr. George H. Brown, a practitioner of Chaunte for more than thirty-five years, has given up practice on account of ill health and has moved to Kansas City. —Dr. Franklin H. Redmond, Osawatimie, has resigned his position on the medical staff of the State Hospital. —Dr. Chilton W. McLaughlin, Kansas City, has been elected vice-president of the Bureau of Associated Medical Fraternities of the National Fraternal Congress.

LOUISIANA

New Home for Medical Society.—A permit has been issued for the erection of a two-story brick building, in New Orleans, to cost \$12,000, for the use of the Orleans Parish Medical Society.

New Sanitarium to be Opened.—The Louisiana Tuberculosis Sanitarium, Hygeia, was opened for inspection September 18. A main building has been erected at a cost of \$6,000, together with several cottages, and a large amount of land has been set aside for cultivation.

New President for State Board.—Dr. Oscar Dowling, Shreveport, has been elected president of the State Board of Health, vice Dr. D. Harvey Dillon, New Orleans, resigned, and assumed the duties of his office September 1. Dr. Dowling announces his plan for an educational health campaign to be initiated at once throughout the state.

City Health Board Organizes.—The New Orleans Board of Health held its monthly meeting September 13. Dr. William T. O'Reilly was reelected chairman of the Board, Dr. Paul E. Archinard, bacteriologist; Dr. Abraham L. Metz, chemist, and Dr. Paul J. Gelpi, Jr., inspector of communicable diseases. It is announced that Dr. William H. Robin will succeed the late Dr. Sidney Theard as secretary and treasurer of the board and that Dr. James A. Henderson will become a member of the board in Dr. Robin's place.

MARYLAND

Hospital News.—The trustees of Elkton Hospital have made an appeal for \$7,000 to enlarge the hospital building. —The directors of Western Maryland Hospital, Cumberland, have purchased for \$3,600, the residence opposite as a home for nurses. This will give ten more rooms for the use of patients. —A new nurses' home and central heating plant are to be added to the Frederick City Hospital. —About \$300 was raised at a picture show and automobile carnival at Havre de Grace, September 14, toward a fund for the proposed hospital in that place.

Baltimore

Sailed for Europe.—Drs. Frank C. Ainley, J. W. Rosenfeld, Lawrence Selling, Caroline B. Towles, and Milton C. Winternitz, all of Johns Hopkins Hospital and Medical School, sailed for Europe September 14, to pursue clinical studies in Germany.

Hospital Reports.—The annual report of the Church Home and Infirmary shows an income of \$73,075 with expenses of \$71,100, leaving a balance in the treasury of \$2,065. —The Maternité Hospital of the University of Maryland reports during the last year 201 confinements in the hospital and 865 in the outdoor department, giving an average of about thirty obstetric cases seen by each member of the graduating class.

MISSISSIPPI

Gift to Hospital.—Mrs. Lemuel P. Conner, Natchez, has donated twenty-four rolling chairs, one hand-lever tricycle, and one child's rolling chair to the Natchez Charity Hospital.

Health Exhibit at State Fair.—The State Board of Health is preparing an exhibit for the State fair this fall which will include drawings and photographs of insects responsible for the spread of typhoid and malarial fevers, as well as the hookworm parasite. Mosquitoes which are malarial carriers will be shown side by side with mosquitoes of the harmless variety, so that the public can learn to distinguish between them. Pamphlets on the cause, prevention and cure of diseases most prevalent in the state will be distributed to the public at the same time. A display of the National Tuberculosis Exhibit is also being arranged for in connection with the State Board demonstration. It is anticipated that a large number of the people who attend the State Fair may be reached in this way.

NEBRASKA

Personal.—Colonel John M. Bannister, Medical Corps, U. S. Army, has retired and will practice ophthalmology in Omaha. —Dr. Howard B. Hamilton, Ainsworth, Iowa, has moved to Omaha.

Medical Schools Open.—The John A. Creighton Medical College, Omaha, opened for its annual session, September 1. —The University of Nebraska, College of Medicine, Omaha, began its school year, September 13.

NEW JERSEY

School Medical Inspectors.—East Orange has a waiting list of physicians who are desirous of becoming medical examiners in the public schools, although it has been reported from some sections of the state that physicians are averse to accepting these appointments on account of the small fees allowed by the school inspection law.

Camden Health Board Tests Candy.—"Kelly" candy balls, a popular confection, are believed to have caused the illness of many children in Camden, but so far only three serious cases have developed. In these the infection first showed itself in blotches and later the tongue became greatly swollen, almost filling the mouth. Some of the candy has been sent to the State Health Board for analysis.

NEW YORK

The Tuberculosis Campaign.—The State Department of Health has assembled a large and comprehensive traveling tuberculosis exhibition, which has formed a very important feature in local campaigns. The work of the immediate future will consist of individual county campaigns, and the use of small tuberculosis exhibitions in many of the smaller towns throughout the state.

Tent Hospital Opened.—The temporary tuberculosis hospital was completed at the Monroe County Farm, Brighton, September 3, and two days later patients were received for treatment. The hospital consists of three apartments, a porch, a sleeping room, and a dining room. The sleeping room will accommodate eighteen patients. It is not expected that the new county hospital will be opened before next spring.

Personal.—Dr. Albert E. Leach of Mount Morris was seriously injured in a collision between his automobile and a locomotive on September 13. —Dr. E. S. McClellan, president of the Saranac Lake Board of Health, was struck by a passenger train, September 3, fracturing a rib, spraining a wrist, and sustaining numerous contusions. Notwithstanding the advanced age of Dr. McClellan, he is reported to be making a good recovery.

New York City

Personal.—Dr. Carlos F. MacDonald has returned from Europe. —Dr. Jacques C. Rushmore, Brooklyn, Dr. and Mrs. Isadore W. Feld and Dr. and Mrs. Elon N. Carpenter have sailed for Europe.

Women to Work for Pure Milk.—An organization has recently been formed by some women at the Hotel Astor, to be known as the International Pure-Milk League. They intend to investigate all matters having a bearing on the production and price of pure wholesome milk. In New York City they will cooperate with the health department.

Better Care for School Children.—The common drinking cup has been banished from the public schools of this city. While great care has recently been exercised in regard to the teeth of the children not so much has been directed to caring for the eyes and this year the following instructions will be pasted in each book:

Never read in bad light. Always hold your head up when you read. Your eyes are worth more than any book to you. Hold your book about fourteen inches from your face. Let the light come from behind or over your left shoulder. Your safety and success depend on your eyes; take care of them. Rest your eyes by looking away from the book every few moments. Avoid books or papers printed indistinctly or in small type. Never read with the sun shining directly on the book. Wash your eyes night and morning with pure water. Be sure that the light is clear and good. Never face the light in reading.

Dr. Maxwell, superintendent of public instruction, who has just returned from Europe, where he made a study of schools, found the German schools far in advance of ours as regards cleanliness and neatness of both rooms and pupils.

NORTH CAROLINA

Land Deeded to Hospital.—The town of Woolsey having lost its charter and become a part of the city of Asheville, the executors of the late Colonel Woolsey have deeded, without reservation, the town hall and adjoining lots to the Mission Hospital, Asheville.

Antituberculosis Association Organized.—On August 23, the Edgecombe County Antituberculosis Association was organized in Tarboro. Dr. S. P. Bass, superintendent of the local board of health, presided, and at the election of officers was made secretary-treasurer of the association.

Personal.—Dr. William H. Moss, who has resided for the last seven years at Atlanta, Ga., has returned to his former home, Charlotte, and will resume practice there.—Dr. William T. Carstarphen, Kittrell, has been elected professor of physiology in Wake Forest Medical School.—Dr. Hubert A. Royster, Raleigh, has been unanimously elected president of the Chamber of Commerce of that city.

Hookworm Investigation.—Dr. John A. Ferrall, assistant secretary of the State Board of Health for Hookworm, working under the Board and the Rockefeller Commission, has completed a careful canvass of the state, and has demonstrated the presence of hookworm in every county. The field is divided into districts and is being actively worked in order to familiarize both the profession and the public with the symptoms, results and treatment of the disorder. The commission is expending \$20,000 a year in the state for this work.

OKLAHOMA

College Opens.—The Oklahoma City department of the State University Medical Society opened for its annual session, September 16, with an address by President A. Grant Evans of the university.

Medical Association to Meet.—The Central Oklahoma Medical Association, which was announced to meet in Chickasha in June last, will hold its meeting in that place October 4, as the guest of the Grady County Medical Association.

Personal.—Dr. Joseph Hensley, Oklahoma City, has resigned as a member of the State Board of Medical Examiners.—Dr. Franklin P. Davis, Enid, secretary of the State Medical Board, has been elected superintendent of the State School for Feeble-Minded, Enid.

OREGON

Raise Money for Hospital.—The first two days in September \$5,000 was subscribed toward the hospital which the Sisters of Providence are planning to erect in Medford at a cost of \$100,000.

State Association Meeting.—The thirty-sixth annual meeting of the Oregon State Medical Association was held in Portland September 7-9. The following officers were elected: President, F. W. Vandyke, Grant's Pass; vice-presidents, Drs. Robert C. Yennet, Portland; Samuel T. Linklater, Hillsboro, and Robert E. Ringo, Pendleton; secretary, Dr. Calvin S. White, Portland; treasurer, Dr. Edna D. Timms, Portland (elected), and councilors, Drs. William House and Noble W. Jones, Portland. The Baker County Medical Association was granted a charter by the association.

PENNSYLVANIA

Physicians of Three Counties Meet.—At the annual meeting of physicians of Dauphin, Lebanon and Lancaster counties, held at Piqua, August 25, the following officers were elected: President, Dr. Warren F. Klein; vice-president, Dr. William M. Guilford, and secretary, Dr. William R. Roedel, all of Lebanon. Lebanon was decided on as the place of meeting for 1911.

Individual Drinking Cups Used.—State Health Commissioner Dixon made public, September 14, the report given him by the Pennsylvania Railroad of the results of the campaign against the common drinking cup. In the Harrisburg Station alone, during the month of August, 3,700 individual drinking cups were used and at Lancaster, 1,540. The figures for other stations were: Parkersburg 200; Coatesville, 300; Downingtown, 195; Wayne, 579; Bryn Mawr, 643; Ardmore, 286, and Columbia 359.

Personal.—Dr. Herbert S. VanKirk, McKeesport, sustained injuries to the foot by contact with the propeller shaft of a gasoline launch in which he was riding.—Dr. Edward R. Plank, Carlisle, has been reelected a member of the local board of health.—Dr. Elmer P. Norris, Newcastle, has been appointed surgeon of the Pennsylvania Brigade, Uniform Rank, K. of P.—Dr. John W. Luther, chief surgeon of the Palmyerton Hospital, underwent operation for appendicitis at the University of Pennsylvania Hospital, September 8.

Philadelphia

Personal.—Dr. Donnel Hughes returned from Europe September 13.—Dr. Charles H. Gardner has been elected surgeon-general of the Union Veterans' Legion.

Hospital Society Elects.—At the June meeting of the Woman's Hospital Medical Society, the following officers were chosen to serve for the ensuing year: Pre-ident, Dr. Mary Getty; vice-president, Dr. Annie L. Connor; secretary, Dr. Margaret A. Warlaw, and treasurer, Dr. Mary T. Miller.

Fire in Tuberculosis Institute.—A fire which originated on the fourth floor of Henry Phipps Institute, August 29, did little damage but caused great excitement. Twenty-five patients were quickly removed from the building, which was saved by the speedy action of a volunteer fire brigade of physicians and nurses.

Asks Money for Home for Feeble-Minded.—A message has been sent to City Councils by Mayor Reyburn asking that body to appropriate \$150,000 for the purchase of 120 acres of woodland as a site for the erection of a home for the indigent and feeble-minded children. This land is on the Delaware River, immediately north of the Torresdale filtration plant.

English Ophthalmologist in Philadelphia.—Dr. Sydney Stephenson, the noted English ophthalmologist, was the guest of honor at a number of entertainments while in this city. On September 13, Dr. Wendell Reber gave a luncheon; on September 14, Dr. W. Campbell Posey gave a luncheon at the University Club and in the evening he was the guest of honor at a dinner given by Drs. L. Webster Fox and S. Lewis Ziegler at the Union League Club.

New Factors in Tuberculosis Fight.—The dedication exercises of the new home of the Jewish Consumptive Institute at Fourth and Water streets, began September 11, and continued throughout the week. The building is equipped with a dispensary for clinical service, a laboratory for microscopic research, and has a staff of physicians, and also one of nurses for visiting patients at their homes.—The Philadelphia Jewish Sanatorium for Consumptives has completed plans for a children's pavilion soon to be erected at the farm in Eaglesville.

Opening of University.—The annual opening exercises of the University of Pennsylvania were held September 23. A new department of tropical medicine has been inaugurated. Among the new members of the faculty of the medical school are: Dr. R. M. Pearce, professor of pathology and research medicine; Dr. A. E. Taylor, professor of physiologic chemistry; Dr. A. N. Richards, professor of pharmacology, and Dr. David L. Edsall, professor of medicine; Dr. Allen J. Smith, formerly professor of pathology, becomes professor of tropical medicine and comparative pathology, with Dr. Damaso Rivas as assistant; Dr. James H. Austin has been appointed demonstrator of pathology and Dr. A. B. Eisenbrey, assistant in research medicine. Dr. Louis A. Durring, who has held the chair of dermatology for many years and a professorship since 1876, has resigned.

The Tyson Portrait for the College of Physicians.—The committee of arrangements for the dinner given to Dr. James Tyson on May 5 finds, after the payment of all bills, that it

has a surplus that has been increased by an unsolicited and generous donation from one of Dr. Tyson's friends, who is not a physician. It desires to add to this surplus a sum sufficient to enable it to employ a competent artist to paint a portrait of Dr. Tyson to be presented to the College of Physicians, of which he is an ex-president, as a further and enduring evidence of the esteem in which he is held by the medical profession. In order to accomplish this, the committee invites contributions from all fellows of the college and especially from those who, from various causes, were unable to subscribe to the dinner. Checks should be drawn to the order of Dr. W. C. Posey, treasurer, and forwarded to him at 2049 Chestnut street.

SOUTH DAKOTA

Change in Medical Board.—Dr. Frank S. Howe, Deadwood, has been appointed a member of the State Board of Medical Examiners to fill the vacancy caused by the resignation of Dr. Hiram E. McNutt, Aberdeen.

State Association to Meet.—The twenty-ninth annual session of the South Dakota State Medical Association will be held in Hot Springs, September 27-29. On the evening of the second day, the society will be guests of Dr. Miller, governor of the Battle Mountain National Sanatorium.

Contracts for Sanatorium Building Let.—The contract has been let to a Rapid City firm of contractors for the following buildings for the South Dakota State Sanatorium for Tuberculosis: Pavilion for patients, cottage for dining room and kitchen, and superintendent's residence. The house already on the site is to be used for quarters for the help. It is expected that the buildings will be completed by December 1, and that patients will be admitted a month later.

TENNESSEE

Eastern Tennessee Physicians to Meet.—The annual meeting of the East Tennessee Medical Society will be held in Bristol, September 29 and 30.

Personal.—Dr. and Mrs. Edwin G. Wood, Nashville, have sailed for Europe, and on their return expect to locate in Toronto, Ont. —Dr. Isaac N. Frost, Memphis, has been appointed local medical examiner for the Panama Canal Commission.

College Opens.—The sixtieth annual session of the Medical Department of the University of Nashville and the University of Tennessee opened September 5. Dr. Robert O. Tucker, dean of the faculty, presided, and in his opening address mentioned that a laboratory of pharmacology, the only one in the state, had been equipped and placed in charge of Dr. Joseph P. Keller; that new equipment to the value of several thousand dollars had been purchased, and that forty new microscopes for the use of students had been ordered and delivered.

TEXAS

State Health Officers' Conference.—The State Health Board announces that the annual meeting of health officers of the state will be held in Houston, September 25-27.

Medical College Opening.—The Medical Department, University of Texas, Galveston, will be opened for its fall term, October 1. Dr. George F. Gracey has succeeded Dr. Arthur E. Austin as professor of chemistry, and Dr. George H. Lee has succeeded Dr. John F. Y. Paine as professor of obstetrics.

Personal.—Dr. Lane B. Kline has been appointed medical missionary to the Philippine Islands under the Foreign Missionary Society of the Christian church. —Dr. Otto Ehlinger, LaGrange, has been elected surgeon to the Agricultural and Mechanical College of Texas, College Station, vice Dr. Joseph R. Lay, resigned. —Dr. Rufus F. Minnock, city physician of Waco, has been appointed chairman of the city health department. —Dr. Frederick J. Combe has been appointed district surgeon for the St. Louis, Brownsville and Mexico Railway, vice Dr. Harry K. Loew, resigned, with headquarters at Brownsville. —Dr. A. Philo Howard, Houston, has been appointed surgeon for the Frisco lines east of Houston.

UTAH

State Association to Meet.—The annual meeting of the Utah State Medical Association will be held in Salt Lake City, October 3 and 4, under the presidency of Dr. Joseph S. Richards.

Personal.—Dr. Patrick S. Keogh of the Keogh-Hammond Hospital, Salt Lake City, who was seriously injured, September 5, is reported to be recovering. —Dr. Frederick Clift, for more than five years assistant physician at the State

Mental Hospital, Provo, has resigned, and will assume a similar position in the Kayville Hospital. Dr. Clift has also resigned as secretary-treasurer of the Utah County Medical Society, and has been succeeded by Dr. Horace G. Merrill.

School Medical Staff Appointed.—The Board of Education of Salt Lake City has nominated the following staff for inspection of children in the public schools: Chief of staff, Dr. Eugene W. Whitney; secretary, Dr. Theodore B. Beatty, secretary of the State Board of Health, and Drs. Samuel G. Paul, city physician, Samuel H. Allen, Stephen L. Richards, Clarence Snow, Jane W. Skolfield, Charles F. Wilcox, Charles I. Douglas, Parley P. Musser, Harry N. Mayo, Luella P. Miles and John F. Critchlow.

VIRGINIA

Medical College Opens.—The Medical College of Virginia opened for its annual session, September 11, with an address of welcome by Dr. Christopher Tompkins.

Personal.—Dr. Sparrell S. Gale, Roanoke, has gone to attend clinics at Rochester, Minn. —Dr. Powhatan S. Schenck has succeeded Dr. Harry R. Dupuy as health commissioner of Norfolk. —Dr. F. L. Banks, Madison county, one of the assistant physicians of the Central State Hospital, Petersburg, has resigned, and has been succeeded by Dr. B. L. Carleton of Essex county.

GENERAL NEWS

Coming Meetings.—The Southern Medical Association will hold its annual meeting in Nashville, November 8-10. —The Medical Association of the Southwest will hold its annual meeting in Wichita, Kan., October 11 and 12. —The American Association for the Study and Prevention of Infant Mortality will hold its annual meeting in Baltimore, November 9-11.

Meeting of French-Speaking Physicians.—At the fourth annual meeting of the Association of French-Speaking Physicians of North America, held in Sherbrooke, Quebec, August 24 and 25, the following officers were elected: Honorary presidents, Drs. J. J. Guerin, and A. Achille Foucher, Montreal; president, Dr. Henri Hervieux, Montreal; vice-presidents, Drs. J. M. Arthur Rousseau, Quebec; Joseph O. Ledoux, Sherbrooke; and Joseph C. H. Gauthier, St. Ephrem d'Upton; secretary, Dr. Joseph Gagnon, Montreal, and treasurer, Dr. Benjamin G. Bourgeois, Montreal.

Mississippi Valley Meeting.—At the thirty-sixth annual meeting of the Mississippi Valley Medical Association, held in Detroit, September 13 to 15, the following officers were elected: President, Dr. Robert H. Babcock, Chicago; vice-presidents, Drs. Arthur D. Holmes, Detroit, and Charles E. Barnett, Fort Wayne, Ind.; secretary, Dr. Henry Enos Tuley, Louisville (reelected); and treasurer, Dr. S. C. Stanton, Chicago (reelected). The selection of a place of meeting and of the chairman of the committee of arrangements for 1911 was left to the Executive Committee with power to act.

Electro-Therapeutists Meet.—The twentieth annual meeting of the American Electro-Therapeutic Association was held in Saratoga Springs, N. Y., September 13-15, and the following officers were elected: President, Dr. Frederick DeKraft, New York City; vice-presidents, Drs. F. Howard Humphris, London, England, and Frank B. Granger, Boston; secretary, Dr. J. Willard Travell, New York City (re-elected); treasurer, Dr. Emil Henel, New York City; registrar, Dr. Frederick M. Law, New York City (reelected); and trustees, Drs. Charles R. Dickson, Toronto, Ont., and Thomas D. Crothers, Hartford, Conn.

Death Rate for 1909.—The death rate in the registration area of the United States for 1909, is lower than that for any previous year; the U. S. Census bulletin on mortality statistics gives the death rate, based on the provisionally estimated population for that year, as 15 per thousand, as against 15.4 for 1908. The bulletin states that it is evident that an era of low mortality has begun and cites the fact that the death rate in England and Wales for the same year was 14.5 and for London was 14. This latter fact demonstrates the fallacy of the idea that high death rates are necessarily found in large cities. The largest number of deaths returned for any month of 1909 was 70,093 for March, and the month having fewest deaths was June. The registration area comprised 55.3 per cent of the estimated population for that year.

Health of the Philippine Islands.—In the report of the Bureau of Health of the Philippine Islands for the quarter ended March 31, Dr. Victor G. Heiser, the director, notes a decrease of 1,025 Americans, 539 Spaniards, 333 other Europeans, and 3,935 Chinese between 1907 and 1910, and an increase

of 16,567 Philipinos and 132 of other nationalities, making a net increase of 10,867.—At the first biennial meeting of the Far-Eastern Association of Tropical Medicine, held in Manila, March 5 to 12 and in Baguio, March 13 and 14, work of especial value was reported in beriberi by Fraser, of the Straits Settlements and Aron, of the Philippine Medical School, showing that an outbreak of the disease in most cases is caused by the continued consumption of polished rice and that the disease is probably due to the deprivation of phosphorus which is polished away during the milling process. It is hoped that by prohibiting the use of polished rice in public institutions, the disease may be eradicated from such places.—Dr. Heiser also notes that the experiments with cancer vaccine made by Dr. Coca and P. K. Gilman, met with excellent preliminary results.—A description of the means by which the leprosy organism may be grown outside of the human body was presented and a paper was also presented by Dr. Strong on his experiences with the Ehrlich method of using arsenophenyglycin for the treatment of surra in horses.—There were reported 578 cases of cholera in the islands. In 1909 there were 2,221 and in 1908, 806 cases. More than 2,500,000 doses of quinin have been purchased and arrangements have been made for gratuitous distribution of the medicine in the malarious sections of the islands.—The outdoor treatment of tuberculosis in the mountains of Benguet has been commenced and a number of patients are now under treatment and making encouraging progress.—The tuberculosis camp at San Juan, near Manila, is being transformed into a suitable sanitary site and soon will be ready to receive patients.

MANILA LETTER

(From Our Regular Correspondent)

MANILA, August 9, 1910.

Prevention of Tuberculosis in the Philippines

Another step forward is to be noted in the progress of preventive medicine in the Philippines. This is expressed in the organization of the National Society for the Study and Prevention of Tuberculosis in the Philippine Islands. In many respects one feels agreeably surprised to find that in this comparatively new country (that is from an American point of view), medicine and the medical sciences are so much to the front and are of such a high standard. From the central government's having a more direct control of sanitation and quarantine than is the case in America, and from the fact that good health is so extremely important and desirable in the tropics, this condition of affairs is in a measure to be expected among the Americans and Europeans. But in spite of this the popular support given to medical problems in general by the Americans and a great number of the Filipinos, and the good spirit in which these are received by the masses of the people, are rather gratifying. Many measures are more easily put into practice in the Philippine Islands than in America. The new National Society for the Study and Prevention of Tuberculosis in the Philippine Islands was organized and had its first meeting in the assembly room of the insular capitol building. It was presided over by the governor-general, and the U. S. Secretary of War, Hon. Jacob M. Dickinson, delivered an address. The organization is about equally well represented by Americans and Filipinos and many of the latter are on important committees. The first main object of the association is one of education and the protection of the people from the infectious cases.

The association starts its work under the most auspicious circumstances. It has the undivided support of the government, the medical profession, the laity, the church (both Protestant and Catholic) and the press. It was brought out at the first meeting that tuberculosis is general throughout the Philippines, that about 20 per cent. of the people of the islands are infected in one form or another, and that the annual financial loss due directly to tuberculosis is from \$20,000,000 to \$60,000,000. The annual death-rate in Manila from tuberculosis is from 5 to 6 per 1,000. In a country whose climate is never severe, where there is little abject poverty and plenty of fresh air this condition of affairs is hardly to be expected. Moreover, the houses are built so that they can be thrown wide open to both sun and air. But the filthy condition in which the people live, the low standard of living, with often insufficient food, and the decided overcrowding in the homes are taken to be the principal factors in the prevalence and spread of tuberculosis. It is even said that the condition in which the inhabitants sleep is directly responsible for the major part of the tuberculosis. From 6 to 20 people usually eat, live and sleep in 1 or 2 small rooms. At night the house is closed up as tight as it is possible to

close a nipa house. All windows, doors and cracks are closed and a little kerosene lamp is kept burning all night to keep out the night air and to drive away the evil spirits. When there are one or two individuals with advanced tuberculosis sleeping among the others and spitting promiscuously about the place it is easy to see how the disease is spread. This overcrowding and the superstition which usually accompanies it promise to be the most difficult obstacles in the fight against tuberculosis.

Among the factors which are calculated not only to improve the general health of the people of the islands but also to aid materially in their education is to be mentioned and particularly emphasized, the work being accomplished by the Bureau of Public Works. This bureau is building good roads throughout the islands, trying to establish a sanitary water supply for every community and is draining many cholera-haunted rice marshes and establishing sanitary irrigation. The attempt to give every barrio pure water is meeting with great success and widespread commendation. Unfortunately the capacity of the bureau in this regard is by no means as great as desirable. In the municipalities and larger towns of the provinces public artesian wells are being dug just as fast as possible. In the smaller towns deep wells enclosed and covered over with concrete encasements and fitted with pumps are being installed. These are usually near the center of the town and near the American schoolhouse. It is useless to add that the health conditions in these communities almost immediately improve. In those regions where cholera is endemic wells are especially urged. In some of these remote districts it almost seems like a liberal education when the native has learned to use and appreciate pure drinking water. To these cholera endemic regions the attention of the Bureau of Public Works has recently been directed. It is proposed to establish a system of irrigation to supplant the present system of stagnant irrigation, and to have it so arranged that the rice fields may be flooded and drained at will, either by a high tide in those districts along the coast, or in the hills from a river or reservoir.

Such is another phase of the American campaign of sanitation and irrigation in the Philippine Islands.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, September 10, 1910.

A Nurse's Mistake: The Danger of the Similarity of the Dram and the Ounce Symbols

It is curious that the danger of the similarity of the dram and the ounce symbols of pharmacy has not received more attention and that cases of poisoning from confounding them are not recorded. Probably the great difference in dose prevents a mistake on the part of the pharmacist, however bad the writing in a prescription. But in the case of nurses, or other persons ignorant of pharmacy, who may have to administer medicine, there is no such safeguard. The reality of the danger is shown by the following case. A woman, aged 45, was admitted into St. Thomas' Hospital suffering from exophthalmic goiter and advanced pulmonary tuberculosis. Her nurse was responsible for giving a sleeping draught of liquor morphine hydrochloridi which was prescribed on the bed-card. The solution was kept in a poison chest in the ward, which was lighted by electricity when the nurse poured out the dose into a graduated measure. The amount ordered was a dram, but the nurse mistook the symbol for ounce and administered that dose. After five minutes she discovered her mistake and called the house physician. He could find no signs of morphin poisoning then or up to the time of the patient's death, and at the inquest he stated that the patient might have died at any time from disease. He did not think that the morphin accelerated death. The nurse said that the symbols for dram and ounce were very similar and that nurses were not trained as to the fatal doses of poisons; they had to find out for themselves. The coroner commented on the danger of having a number of closely-written lines containing the names of several poisons on a bed-card and on the danger of permitting nurses to measure poisons. The jury found that the woman died from the effects of disease accelerated by the shock following the treatment made necessary by the nurse's mistake, and recommended that directions for administering medicine should be written in plain English instead of "hieroglyphics."

Mortality Due to Wild Animals in India

The "Statistical Abstract" relating to British India, which has just been published, shows a decline in the deaths due to wild animals. Whereas in 1899 these amounted to 27,585,

in 1908 they had fallen to 21,904. Of these deaths the snake is responsible for the overwhelming majority—24,619 in 1899 and 19,738 in 1908. There are curious fluctuations in the man-eating propensities of the tiger. In 1908 he killed 1,908 persons; in 1906, 690, and in 1901, 1,171. The killing of cattle by wild animals is a fairly constant factor—98,687 in 1899 and 98,307 in 1908. In these figures the leopard is an easy first and the tiger a good second. These animals alone ate over 71,000 cattle while wolves accounted for another 10,000. On the other side of the account there is the satisfactory total of 17,296 wild animals and 70,494 snakes killed in 1908.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 9, 1910.

Liquor Dealers Protest Against Temperance Agitation

A committee representing the organized restaurant and saloon keepers has recently presented a protest to the government against the "campaign being waged in the name of hygiene by the temperance societies." This protest against the antialcohol crusade is eloquent testimony to the disregard for public health interests on the part of the liquor dealers and should suffice to discredit certain other demands they are making at this time.

Proposed Changes in the Outlay for Public Charities

Since 1905, when the law went into effect which provided for old age pensions, it has been felt more and more that it would be better policy to do more for the welfare of the children who are some day to become the vital force of the nation. At present the city of Paris, for example, expends yearly scarcely two million dollars for all its maternities, children's hospitals and asylums, milk stations, day nurseries, fresh-air schools, etc. On the other hand, for the aged and the insane it expends over ten millions. This lack of proportion between the provisions for the rising and the declining generations is particularly shocking on account of the prevailing low birth-rate, which renders it peculiarly imperative to save as many as possible of the children that are born and to reduce the number of stillbirths by proper care of pregnant women. These ideas have inspired M. A. Rendu, a member of the city council and at one time president of the board in charge of the public charities, the *Assistance Publique*, to propose in the council a measure designed to divert more of the funds to the care of young girls, mothers, infants and children, instead of devoting them so predominantly to the care of the aged and the insane. His plan does not contemplate depriving the aged and the insane of their support, but it proposes to board them out in rural districts. All the aged who were not born in Paris and have not founded a family there would be removed to their native province and supported there either in local asylums or with relatives, their pension of 30 francs (\$6) a month to be forwarded regularly to them. This would relieve the Paris asylums where most are now housed and where it costs for each over \$160 a year; only those too infirm to be moved or without any relatives would be retained there. The same plan could be followed with the insane, whose support in the Paris asylums costs over \$200 a year apiece. Rendu believes that large sums would thus be saved; this amount would then be available for increasing the number and scope of the institutions and agencies for aiding pregnant women and mothers, infants and older children; that is, the elements on which the future of the race depends and which at present rank second or third in the outlay for public charities.

Contract Practice in France

The lodges and sick benefit societies have multiplied so rapidly in France that now they list about five million members. Unfortunately this development has taken place in large part at the expense of the medical profession. The lodges assume the expense of medical attendance for their members and contract with certain physicians at a very low rate. Many young doctors just entering on practice contract with the societies in this way, hoping that the number of patients will make up for the smallness of the individual fees. Some physicians are even complaisant enough to accept the deplorable system of contracting to attend the members for a certain lump sum, determined in advance, representing a certain small sum per member per year. The result of this contract work is that physicians may receive \$480 a year and have to make 4,000 calls for visits, which is only a little over ten cents a visit. This situation is particularly distressing at

present, when physicians in various parts of the country, and especially at Paris, are striving to raise their fees. The lodges and benefit societies are also beginning to see the folly of attempting to estimate in advance the demands that will be made on the lodge doctor, and the members are beginning to realize that at a ten-cent rate the physician may be inclined to neglect them for his more remunerative patients. The French law compels the societies of this kind to keep a certain proportion of their funds in reserve so that they are unable to dispose of them at will, but the members' fees might be raised a little, enough to do some justice to their medical attendants. Another point on which the profession and the lodges are disputing is that the members should not be restricted in their choice of a physician but should be entitled to call on any medical man; this "free choice" would distribute the work more evenly among the local physicians while guaranteeing better their absolute independence. The lodges state that they cannot permit this free choice without a certain guarantee and right of control to eliminate abuses. A solution of the difficulty has been proposed by M. Emile Loubet, the former president of France, who is much interested in the development of the mutual aid societies; he proposes the organization of boards of arbitration at Paris and in the various provinces to settle all disputes that may arise in the course of contract practice. Conditions at present are threatening the welfare both of the physicians and of the societies.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 2, 1910.

Marriage Statistics of the German Empire

If the marriageable age for males is placed at 21 as the lower limit and 70 as the upper, there were on December 1, 1900, when the last official census was taken 14,045,033 males of marriageable age. Of these 4,044,206 were single, 9,456,241 married, 544,586 widowed or separated. There were therefore at that time in Germany 4,588,792 marriageable males. In the course of ten years from 1899 to 1908, 4,803,399 marriages were celebrated. 480,400 males, on the average being married yearly, i. e., 1,047 for every 10,000 marriageable men.

If we place the beginning of marriageable age for women at the end of the fourteenth year and the upper limit at 70, there were on December 1, 1900, in Germany 18,540,081 female persons of marriageable age; of these 7,105,906 were single, 9,622,246 married, 1,811,929 widowed or separated. There were therefore in Germany 8,917,335 marriageable women. In the decennium from 1899 to 1908, 480,400 women on the average married yearly, or 539 for every 10,000 marriageable women. In 1899 the number of marriages in the German empire was 471,519. The number of marriages sank in 1902 to 457,208, and has risen from that time to 1907. Last year it amounted to 503,964. In the last five years ending in 1905 the number of marriages had risen 10.3 per cent. while the population and probably also the number of marriageable persons had risen in the same time only 7.6 per cent. In 1908 the figure had again sunk to 500,620.

Tuberculosis in Bavaria

At one of the latest sessions of the Munich medical society, Professor Dieudonné announced that the mortality from tuberculosis in Bavaria had materially improved. In general the mortality of infectious diseases in Bavaria has markedly diminished in the last few years, from 77.7 per cent. in the year 1877 to 38.4 per cent. for the year 1905, or reckoned for 10,000 inhabitants, from 270 to 187. But the records show that among the religious sisterhoods (*die barmherzigen Schwestern*), who are mostly engaged in nursing, 1,366 or 56.2 per cent. died of tuberculosis in the years from 1899 to 1908. As to the methods of infection by tuberculosis, a number of cases have been observed in Bavaria in which children lived for a long time exclusively on raw milk from cows with tuberculosis of the udder without becoming sick. In one case the calf of a cow with diseased udder perished from bovine tuberculosis (*Perlsucht*) while two persons who drank the same milk at the same time remained healthy. As to the question of inhalation and intestinal tuberculosis, the result of experiments has shown that a primary tuberculosis from feeding may be brought about, but that a much larger number of bacilli are necessary than in the case of infection by inhalation. The number of bacilli necessary to produce disease by inhalation and by feeding stand in the relation of 62 to 6,000,000. The bovine type was never found in the sputum of adults.

Marriages

- DAVID I. MACHT, M.D., to Miss Sarah Adler, both of Baltimore, September 5.
- JOHN CHARLES FALK, M.D., to Miss Ida Cartman, both of St. Louis, September 8.
- THOMAS P. LYNAM, M.D., to Miss Mary Ellen Boyle, both of Chicago, September 14.
- FREMONT C. KNIGHT, M.D., Waukegan, Ill., to Miss Iva M. Fischer of Chicago, September 6.
- JOHN E. MCARDLE, M.D., to Miss Henrietta Grimme, both of Fort Wayne, Ind., September 6.
- RANLPH HUDSTON, M.D., to Miss Ethel Jean Simpson, both of Denver, Colo., September 7.
- CLYDE WHITNEY DICK, M.D., Wilcox, W. Va., to Miss Mattie Ellen Selfe of Tazewell, Va., July 14.
- ANGELO JOHN SMITH, M.D., to Miss Lucy Stuart Bradley, both of Yonkers, N. Y., September 8.
- WILLIAM H. THEARLE, M.D., U. S. Army, to Miss Bertha Mills of Waynesboro, Pa., September 5.
- WILLIAM J. WILLS, M.D., Sedalia, Mo., to Miss Lulu E. Nichols of Springfield, Mo., September 1.
- GEORGE WILLIAM MILLER, M.D., Norristown, Pa., to Miss Mary E. Platt of Philadelphia, September 10.
- JULIUS HENRY POWERS, M.D., Saginaw, Mich., to Miss Lenore M. Beattie of Ionia, Mich., September 5.
- IRA NORMAN GATES, M.D., Panama, Canal Zone, to Miss Bessie Annis of Kennewick, Wash., August 30.
- GEORGE BRUCE LEMMON, M.D., Springfield, Mo., to Miss Mary Eugenia Harrell of Pasadena, Cal., September 8.
- JACOB WHEELER BIRD, M.D., Sandy Springs, Md., to Miss Mary McIntire Wilson of Centreville, Md., September 7.
- CLINTON KITTO SMITH, M.D., Alamosa, Colo., to Miss Jane Esther Thayer of Evanston, Ill., in St. Louis, September 7.

Deaths

Edward Ely Van De Warker, M.D. Albany (N. Y.) Medical College, 1863; chairman of the section on obstetrics and diseases of women of the American Medical Association in 1887; formerly assistant surgeon and surgeon of the One Hundred and Sixty-second New York Volunteer Infantry; surgeon in chief of the Third Brigade First Division Nineteenth Army Corps; medical director of the First Provisional Division of Georgia, and chief medical officer of the District of the Ocmulgee during the Civil War; formerly president of the Onondaga County Medical Society, Central New York Medical Society, Syracuse Medical Society, and Syracuse Academy of Medicine; a member of the American Gynecological Association; surgeon to the Central New York Hospital; senior surgeon to the Woman's and Children's Hospital, and consulting surgeon to St. Anne's Maternity Hospital; formerly school commissioner; died at his home in Syracuse, September 6, aged 68.

Marcus Rosenwasser, M.D. University of Würzburg, Germany, 1867; a member of the American Medical Association; formerly professor of diseases of women in Wooster University Medical College, and afterwards at the College of Physicians and Surgeons, Cleveland; once vice-president of the American Association of Obstetricians and Gynecologists; gynecologist to the Cleveland General and Mount Sinai hospitals; consulting gynecologist to the City Hospital, and physician to the Jewish Orphan Asylum; during 1901 and 1902, president of the local board of health; died at his home in Cleveland, September 4, from angina pectoris, aged 64. At the funeral services, held September 6, Drs. George W. Crile, John H. Lowman, Charles F. Hoover, and Charles B. Parker, former colleagues of Dr. Rosenwasser, acted as honorary pallbearers.

Siméon Starkweather French, M.D. Geneva (N. Y.) Medical College, 1842; for many years a member of the American Medical Association; formerly president of the Michigan State Medical Society, Calhoun County Medical Society, Battle Creek Academy of Medicine, and Kalamazoo Academy of Medicine; for three years surgeon of volunteers during the Civil War; local surgeon of the Grand Trunk Railroad for eighteen years; for twelve years health officer; two terms mayor, one term alderman, two years superintendent of schools, eight years inspector of schools, and four years

supervisor of Battle Creek, Mich.; who is said to have presented the resolutions which resulted in the "Under the Oaks" meeting at the organization of the Republican party; died at his home in Battle Creek, September 10, aged 94.

Sidney L. Theard, M.D. Tulane University, New Orleans, 1891; a member of the American Medical Association; in 1898 appointed sanitary officer of the State Board of Health, and a few months later made secretary, sanitary officer and treasurer of the New Orleans City Board of Health, holding these offices up to the time of his death; died at his home September 5, from paralysis, aged 42. The funeral was attended by more than fifty members of the parish medical society, and the mortuary committee of that association acted as honorary pallbearers.

James Donnelly, M.D. University of Michigan, Ann Arbor, 1883; a member of the American Medical Association; associate professor of surgery in and dean of Toledo Medical College; local surgeon in Toledo for the Lake Shore and Michigan Southern Railway, and the city fire department; a member of the school board for several terms; United States pension examiner for the district; died in St. Vincent's Hospital, Toledo, September 4, from typhoid fever, aged 53.

Adam B. Dundor, M.D. Jefferson Medical College, 1864; a member of the American Medical Association, and American Academy of Medicine; for about twenty-five years a member of the board of health of Reading, Pa., and president of the board for nine years; one of the founders and a member of the staff of the dispensary and Reading Hospital for nearly a quarter of a century; died at his home in Reading, September 3, from paralysis, aged 72.

Emory M. Lyon, M.D. University of Vermont, Burlington, 1862; a member of the Medical Society of the State of New York, and formerly president, secretary, and treasurer of the Clinton County Medical Society; health officer of Plattsburg, a member of the pension board for eighteen years, and surgeon for the Home for the Friendless; a veteran of the Civil War; died at his home in Plattsburg, September 7, aged 74.

Stephen Albert Russell, M.D. University of Buffalo (N. Y.) 1871; a member of the American Medical Association; city physician and health officer and alderman of Fulton, N. Y.; attending physician to the City Hospital, and consulting physician to the Oswego County Hospital; local surgeon for the New York, Ontario and Western Railroad; died at the Lee Memorial Hospital, Fulton, September 5, from cerebral edema, aged 60.

John Troutman, M.D. Missouri Medical College, St. Louis, 1877; of Kansas City, Kan.; a member of the American Medical Association, and American Electrotherapeutic Association; a member of the medical staff of Bethany Hospital, Kansas City, Kan.; professor of electrotherapeutics in the Kansas State University; died at his old home in Wooster, Ohio, September 4, after a surgical operation, aged 65.

Francis Hart Stuart, M.D. Long Island College Hospital, Brooklyn, 1873; a member of the American Medical Association and American Academy of Medicine; formerly president of the Brooklyn Pathological Society; obstetrician to the Brooklyn Hospital; died at his home in that city, September 4, from heart disease, aged 64.

J. A. Gray, M.D. Toronto School of Medicine, 1872; for many years coroner for the county of Peterboro, Ont., and local surgeon for the Canadian Pacific Railway at Peterboro; fell from a window of his house, June 14, and sustained injuries from which he died in the Nicholls Hospital, June 14.

Joseph Orpheus Lieuellen, M.D. Starling Medical College, Columbus, Ohio, 1898; a member of the American Medical Association; died at his home in Maineville, Ohio, September 5, from the effects of a gunshot wound of the head, self-inflicted it is believed while despondent on account of illness, aged 36.

William Henry Path Evatt, L.R.C.S., Ireland, 1879; of Chicago; a member of the Illinois State Medical Society; while walking on the tracks of the Metropolitan Elevated Railroad, September 12, was struck by a train and received injuries from which he died a few hours later, aged 55.

Sturley C. Fetzer, M.D. Western Pennsylvania Medical College, Pittsburg, 1904; of Sheridan, Pa.; a member of the Chartiers Valley Medical Society; died in the Allegheny General Hospital, September 3, from appendicitis for which four operations had been performed, aged 28.

Louis Edmonds, M.D. Harvard Medical School, 1893; of Boston; a member of the American Medical Association; superintendent of Penikese Hospital for Lepers for more than

two years; died in the City Hospital, Boston, September 1, from cancer of the stomach, aged 64.

John Conway Rogers, M.D. Harvard Medical School, 1864; vice-president of the Washington County (Maine) Medical Association; assistant surgeon in the army for one year during the Civil War; died at his home in Pembroke, August 22, from heart disease, aged 75.

William Robert Wall, (license, Iowa, 1886): a member of the Iowa State Medical Society; a veteran of the Mexican and Civil wars; for more than forty years a practitioner of Montonville, Iowa; died suddenly at his home, September 4, from heart disease, aged 88.

Emil Wahl, M.D. University of Leipsic, Germany, 1884; a member of the American Medical Association; one of the best known practitioners of Milwaukee; accidentally shot and killed himself in a boat while hunting at Muskego Lake, September, 9, aged 48.

Lydia Sayre Hasbrouck, M.D. New York Hygieo-Therapeutic College, New York City; for nearly half a century a practitioner; a lecturer and pioneer in the dress-reform movement; died at her home in Middletown, N. Y., August 27, aged 83.

John W. Dashiell, M.D. University of Maryland, Baltimore, 1843; one of the oldest and most widely known practitioners of Somerset county, Md.; for several years town commissioner of Princess Anne; died at his home in that town, September 4, aged 93.

John Edmond Faber, M.D. Washington University, St. Louis; 1869; a member of the Missouri State Medical Association; while working in the laboratory of his son in St. Louis, September 5, died suddenly from cerebral hemorrhage, aged 78.

Stuart Arthur Ashton, M.D. University College of Medicine, Richmond, Va., 1907; of Colonial Beach, Va.; a member of the Medical Society of Virginia; died in Garfield Hospital, Washington, September 9, from anterior poliomyelitis, aged 25.

James Henry McNerny, M.D. Yale University, New Haven, 1891 of New York City; assistant surgeon of the New York General Memorial Hospital; died at his summer home in Mount Vernon, September 5, from heart disease, aged 50.

Nathaniel T. Dulaney, M.D. Jefferson Medical College, 1856; formerly president of the Tennessee State Medical Association; and for six years a member of the state legislature; died at his home in Bristol, September 3, aged 76.

Morris Clifford Hutton, M.D. University of Kansas, Kansas City, 1906; of Kansas City, Kan.; physician to the Swift Packing Company; died from gangrene at the Bell Memorial Hospital, Rosedale, Kan., August 31, aged 26.

John P. Malcolm (license, Delaware); for thirty-five years a practitioner of Wilmington; at one time coroner's physician and for several terms city vaccine physician; died at his home, September 7, from paralysis, aged 61.

William Howell Drake, M.D. Victoria College, Coburg, Ont., 1857; a member of the College of Physicians and Surgeons of Ontario; died at his home in Windsor, September 6, from arteriosclerosis, aged 78.

James A. Atkisson, M.D. University of Nashville, 1880; a member of the American Medical Association; local surgeon at Morehouse, Mo., for the Frisco System; died at his home, September 1, aged 54.

William M. Yater, M.D. Tulane University, New Orleans, 1885; a member of the State Medical Association of Texas; died suddenly at his home in Cleburne, September 9, from heart disease, aged 47.

Homer K. Castle, M.D. Eclectic Medical University, Kansas City Mo., 1903; a practitioner for twelve years; died at his home in Kansas City, September 5, from heart disease, aged 61.

Sarah Elizabeth Wilder, M.D. Boston University School of Medicine, 1879; of Dorchester, Boston; died recently at her summer home in Agawam, Mass., from cerebral hemorrhage, aged 74.

Edward D. Yeates, M.D. Tulane University, New Orleans, 1870; of Starkville, Miss.; a Confederate veteran; died at the home of his son in Grenada, Miss., September 1, aged 65.

Ferdinand A. Steffen, M.D. University of Greifswald, Germany, 1882; died at his home in College Point, Long Island, N. Y., September 9, from cerebral hemorrhage, aged 56.

William Thomas Evans, M.D. Tulane University, New Orleans, 1871; a member of the State Medical Association of Texas; died at his home, in Jewett, May 28, aged 69.

Pharmacology

STRYCHNIN ARSENATE REFUSED RECOGNITION

Report of the Council on Pharmacy and Chemistry

The Council, after considering the advisability of admitting to New and Nonofficial Remedies the unofficial, non-proprietary preparation, strychnin arsenate, decided not to admit it, and authorized publication of the following report.

W. A. PUCKNER, Secretary.

Strychnin arsenate is a compound of the alkaloid strychnin with arsenic acid, containing between 68 and 70 per cent. of anhydrous strychnin. It is a white, crystalline powder of small, colorless or faintly yellowish, transparent or slightly opaque prisms, or in white acicular crystals, odorless but extremely bitter. It is slowly soluble in about 20 parts of water at 25 C., more readily soluble in hot water, slightly soluble in alcohol, insoluble in chloroform or ether.

After considering the properties of this substance the Council voted not to accept it for N. N. R., as there is no sufficient reason for combining two powerful remedies in such form. As a chemical combination there appears to be no objection to it, as the compound is sufficiently definite, but the readiness with which the salt separates into its constituents, strychnin and arsenic acid, indicates that it can present no advantages over a mixture of its components so far as pharmacologic action and therapeutic use are concerned. On the other hand, it is both unscientific and irrational to prescribe two such energetic remedies having quite different indications under such a fixed form that the efficient dose of one may involve an unsuitable and perhaps dangerous dose of the other.

If a dose of strychnin arsenate equivalent to 0.002 gm. (1/32 grain) of strychnin sulphate is given, the patient would receive about 0.00063 gm. (1/100 grain) of arsenic acid, which is about one-fifth the official dose. On the other hand, strychnin arsenate cannot be used to bring out the therapeutic effects of arsenic in cases in which it is necessary to push the latter remedy, because this would necessitate the giving of dangerous doses of strychnin. A much more appropriate and scientific procedure would be to prescribe the medicines separately or in an extemporaneous pill or solution in which the proportions of the two ingredients could be changed from time to time according to the varying indications in the particular case.

FRUITOLA

Olive Oil and Seidlitz Powders as a Fake Gallstone Cure

The quack and the exploiter of "patent medicines" revel in the spectacular; any unusual property possessed by a drug, whether as a physical characteristic or in pharmacologic action, is quickly utilized by the nostrum vender for his financial profit.

For years an enterprising faker who advertised a "cure" for Bright's disease sent out small vials—free—containing a weak solution of silver nitrate. The victim was instructed to make a "uranalysis" by adding the contents of the vial to a small quantity of his urine. "If a white precipitate follows," wrote the quack, "you have Bright's disease!" As the chlorides naturally present in every urine caused a precipitate the layman was duly impressed with his dangerous (?) condition and bought the "cure."

Another bright mind took advantage of the physical properties of an acidulated solution of quinin sulphate. This solution, as all physicians know, has a very decided fluorescence, and the somewhat uncommon appearance was ascribed by the medical faker to radium. This "radium solution" was sold at an outrageously high price as a "sure cure" for cancer.

For many years the kidney disease "curer" has taken advantage of the power of methylene blue to color the urine of the person taking it, and no doubt thousands of laymen ignorant

of this property have been frightened by its use into believing that the integrity of their kidneys was seriously impaired.

Of more recent origin is what may be called the "fake gall-stone trick" which is now being industriously worked in many parts of the country. Originally operated by traveling fakery, it has lately been adapted to the exigencies of the "patent medicine" industry. The principle on which this fake depends is the well-known fact that giving a patient massive doses of some bland oil will result in the passing of soapy concretions. These lumps, greenish in color and of varying sizes, are easily mistaken by the layman for "gallstones."

There are several modifications of this "gall-stone cure" fake, but the most widely advertised is that sold by the Pinus Medicine Company of Los Angeles under the name "Fruitola." It is usually exploited in connection with another nostrum—"Traxo"—put out by the same concern. Many physicians have written to THE JOURNAL, telling the experiences of some of their patients who had taken "Fruitola" for the "removal of gallstones." The following from Dr. James C. Gill of Chicago is typical:

"I am sending an advertisement of a 'patent medicine' called 'Fruitola,' which has been extensively advertised for some time. The fraudulent character is so evident that it is a great imposition on the public to allow such a fraud to be perpetrated. I am also sending what they claim to be able to rid the system of, namely, 'gallstones' (3).

"One of my patients, a young woman, took the contents of this bottle, as well as the powders which accompany the liquid as part of the treatment. Several hours after taking the medicine there were several painful evacuations, in which there appeared a large number, probably two dozen or more, small greenish masses about the size of an ordinary garden pea. The young woman was very much frightened, thinking that they were really gallstones and that she was in a serious condition."

Of course the "gallstones" were simply soapy concretions that usually follow the administration of massive doses of oil.

"Fruitola" consists of an 8-ounce bottle of oil and six powders, four of the latter being in blue papers and two in white. The following directions are given on the bottle:

"At 3 o'clock in the afternoon, dissolve the contents of two blue papers in a half glass of water, add the contents of one white paper and drink. At bed-time squeeze a little lemon juice into a glass, pour in the contents of the bottle, squeeze a little lemon on top and drink at once. Keep a little lemon near in case it shows a tendency to rise.

"As early as possible in the morning take the rest of the powders. When the medicine operates use a vessel partly filled with water, pour in more water or stir the contents, and the gallstones will float on top in the shape of dark green lumps, varying in size from a pin head to a hickory nut, in bad cases even larger."

To determine the character of the oil and the composition of the powders an analysis of "Fruitola" was made in the Association laboratory. The chemists' report follows:

LABORATORY REPORT

An original package of "Fruitola" purchased on the open market was submitted to the Association laboratory for examination. The accompanying labels [One of these labels is reproduced on this page.—Ed.] appeared on the carton and bottle.

Other labels describing the use of the preparation were also on the bottle. The carton contained besides the bottle, two sets of powders, one set wrapped in white, and the other in blue paper.

The bottle contained a transparent amber-colored oil, having an odor of anise and a bland taste. From its physical

properties and chemical composition it was concluded that the substance was olive oil, flavored with a trace of anise.

The powder in the white papers was subjected to chemical tests, and found to be tartaric acid. The identity of the constituents and their quantitative estimation indicated that the powder in the blue papers was a mixture of approximately one part sodium bicarbonate and two parts Rochelle salts—sodium potassium tartrate.

From the foregoing it is concluded that the liquid portion of "Fruitola" is olive oil flavored with anise while the powders accompanying the liquid are the well-known seidlitz powders.

CONCLUSION

Here, then, we have the fake in a nutshell: Olive oil and seidlitz powders. That this combination will produce a good imitation of what the average man imagines to be gallstones is undoubtedly a fact. A thorough cleansing of the intestinal tract by means of laxatives not too drastic in action will produce a temporary feeling of well-being in a person who is chronically constipated, and this fact alone should make it easy for the exploiters of "Fruitola" to get all the "testimonials" they want.

That persons should be misled of a dollar, however, for the privilege of having their bowels moved and being made into a peripatetic soap factory may seem humorous—but it is an outrage nevertheless. To such as wish to make the experiment—and it is one that is by no means free from danger in all cases—we would suggest the following procedure as equally efficacious and much less expensive: Buy 20 cents' worth of olive oil and a nickel's worth of seidlitz powders. You then have all the paraphernalia necessary for the production of home-made gallstones. All that is required is to take the oil and powders and then practice watchful expectancy. The expected will happen.

1. The oil was insoluble in alcohol but soluble in chloroform. The saponification number of the oil was found to be 190.6. This with the other properties of the oil indicated that it was olive or cotton-seed oil. Identity tests were made indicating the absence of cotton-seed oil and suggesting olive oil. As a further check the iodine absorption number was measured and found to be practically that of olive oil.

2. The contents of the powders in the white papers weighed 4 gm. each. The substance was white in color, odorless, with an acid taste and readily soluble in water. Ignition caused decomposition and combustion of the powder and an odor of burnt sugar. The aqueous solution of the powder was acid in reaction and appeared to be free from metallic elements. These properties suggested some solid organic acid. This substance responded to identity tests for tartaric acid. As a verification, quantitative estimations were made and the substance found to be tartaric acid.

3. The contents of the powders in the blue papers weighed 8 gm. each. The substance was found to be a white, odorless powder, soluble in water and having at first a cooling and then a bitter-salty taste. The aqueous solution of the powder effervesced on the addition of acid. Qualitative tests indicated the presence of sodium, potassium, carbonate and tartrate. The presence of other metals or acid radicals could not be demonstrated. The tests indicated the powder to be a mixture of a bicarbonate, probably sodium bicarbonate, and a tartrate, probably sodium potassium tartrate. Titration of the aqueous solution of this powder required an amount of standard acid equivalent to approximately 33 per cent. sodium bicarbonate. To check this estimation and also to determine whether or not the other constituents were present in the proportions to form sodium potassium tartrate, the substance was converted to carbonate by charring, the char leached, and the aqueous solution titrated with standard acid. The quantity of standard acid required in the direct titration was subtracted from the total acid used, leaving the quantity of acid required to neutralize the carbonates formed by charring. The acid thus required for the carbonate corresponded to approximately 66 per cent. sodium potassium tartrate. Showing the powders in the blue papers to be a mixture of one part sodium bicarbonate and two parts sodium potassium tartrate.

ODOL

A correspondent asks for the formula of "Odol," a somewhat expensive English toothwash. It is advertised to an enormous extent in Great Britain, but has not as yet been given any great degree of publicity in this country. It has been claimed that the preparation is a by-product of the salol factories, though this has been denied. Formulas representing the results of various analyses have appeared in German pharmaceutical journals, and the following, by Aufrecht, is from Hager's *Handbuch der Pharmaceutischen Praxis, Ergänzungsband*, Ed. 1908.

Alcohol	\$9.00 per cent.
Water	8.00 per cent.
Menthol	2.00 per cent.
Saccharin	0.05 per cent.
Peppermint oil	0.05 per cent.
Clove oil	0.10 per cent.
Salol-like substance	0.05 per cent.

Correspondence

Hexamethylenamin in Poliomyelitis

To the Editor:—The article in THE JOURNAL, September 17, has crystallized my intention to send you a suggestion in regard to the treatment of the epidemic anterior poliomyelitis. There can no longer be any question as to the nature of this disease, undoubtedly an infection localizing in the spinal canal. The well established fact that hexamethylenamin is excreted or secreted in the cerebrospinal fluid suggests its possible use in this disease.

Within the past few weeks I have seen two instances of this disease, shortly after the onset of paralytic phenomena and have given large doses of urotropin (hexamethylenamin). In neither instance did the paralysis extend and both patients made good recoveries.

It is superfluous to say that nothing can be concluded from such an experience, but in view of our desperate helplessness in such cases, a drug, backed as hexamethylenamin is by some experimental work, may be tried.

ROBERT B. PRERLE, Chicago.

Medical Bibliography

To the Editor:—Medical bibliography is a subject of which the average practitioner knows little, and cares less. Yet with the constantly increasing mass of medical literature, and the growing army of investigators, some familiarity with what is being done in medical science is highly desirable to every intelligent member of the profession, and indispensable to any one who is attempting to do original work. The lack of this knowledge has often led to much that is both laughable and tragic in the breathless announcement, by men whose enthusiasm has outrun their learning, of facts already old and well known.

We must first of all realize that the living, growing body of medical science is in its periodical literature, and that text-books are only imperfect abstracts or summaries made for convenience, by which some acquaintance with certain facts is made possible for those to whom the more extended sources of information are inaccessible, or to whom more detailed knowledge is unnecessary. Medical literature at large, that is, in what may be called its raw state, contains a large mass of very diverse material; some of it no more than a gathering together of common-places; some of it a valuable generalization from known facts, and some of it, first-hand additions to scientific knowledge. A reference is usually made for the purpose of giving the authority for some statement, or a series of references, forming a "bibliography," for the purpose of giving the sources from which the present state of knowledge about a given subject has been derived. The proper work of the bibliographer is to digest the raw material of medical literature and to eliminate that which is irrelevant and useless, so that in the end, his "bibliography" may be complete in all essential particulars,

carrying no waste matter to confuse future students and squander their time.

In order that this may be done most effectively, and with the utmost economy in labor and time both to the bibliographer and student, certain conventions as to the form and arrangement of references should be adopted. It would be well if we could all agree that all references appearing in medical literature should be made to conform to the type or form adopted by the *Index Medicus* (e. g., Doe, (J.). The functions of lymphoid structures, *Amer. Jour. Physiol.*, 1909, xx, 617.) Where the author has examined the original of the references, this would always be possible, and it would materially facilitate their use. Second-hand references, those which a writer incorporates in a bibliography on the authority of some other person, knowing nothing personally of their content or accuracy, should be marked in some distinguishing fashion.

I have before me a reprint, just received, from a young and brilliant colleague, containing the account of some interesting original researches. A bibliography is appended, containing about 500 references. Of these, not one gives the title of the paper referred to; many give no page numbers; many give no year of publication, and many others fail to give the volume. The verification of such a bibliography, even if one were in the Surgeon-General's Library, would be an interminable labor. On the whole, it looks more like a purely ornamental addendum to the simple account of some scientific investigations, than like anything of real assistance to future students.

If our medical colleges could add to their courses a few lectures on the use of medical literature, or a definite course in bibliographic research, it would be not only of immense value but of fascinating interest to all so fortunate as to participate. We should soon have a class of medical graduates whose horizon would not be limited by the text-books they used in college and what their professor said.

And, finally, medical editors have at their command the most powerful means of improving the whole situation, not only by the publication of "Indexes," as some now do, nor by abstracts of current medical literature, which is most useful, but by educating their contributors and readers in addition, to that accuracy and uniformity in bibliographic matters which would eventually be helpful to us all.

HAROLD WILSON, Detroit.

[COMMENT:—The failure of authors to give complete bibliographic references, accurately and uniformly, constitutes one of the trials of the editor. THE JOURNAL has prepared a pamphlet on "Bibliographic Style" to which all references in THE JOURNAL and in *The Archives* are made to conform. Authors generally fail to follow any consistent system in preparing their references to other articles. In some cases, doubtless, it is too much to expect that they shall provide every detail. It is a far different matter, however, for an author to have his stenographer copy on his manuscript a lot of references that he finds tacked on some other article on the same subject. Often this seems to have been done without verification, without completion, without any reason apparent save the desire to have a bibliography with the article. Some one has said that this ought to be made gross unprofessional conduct—a sentiment with which many will sympathize who have tried to make use of such an abomination.—Ed.]

Maritime Quarantine.—In Bulletin 34 of the Public Health and Marine-Hospital Service the facts of maritime quarantine practice are arranged in a compact and interesting form. The boarding, inspection and judgment of vessels, quarantine treatment, station management, descriptions of stations, duties of officers, disinfection and disinfectants, apparatus, etc., are all concisely described and freely illustrated with half-tones. It contains valuable information not only for the maritime quarantine service, but for sanitarians and health officers generally.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ARGYLL ROBERTSON—A BIOGRAPHIC NOTE

To the Editor:—Please give a brief account of Argyll Robertson.

ANSWER.—Douglas Argyll Robertson was born at Edinburgh in 1837, his father being a distinguished surgeon. He received his medical training in Edinburgh and St. Andrews, from which latter university he graduated in 1857. He then studied ophthalmology in Prague under Arlt, and in Berlin under Graefe. He took the fellowship of the Edinburgh College of Surgeons in 1862. In 1867 he was appointed assistant ophthalmic surgeon to the Royal Infirmary; in 1870 he was made co-equal with his senior colleague, Mr. William Walter, and in 1882 had for a time sole charge of the ophthalmic department. He continued to hold the senior post until his hospital retirement in 1897, when he was appointed consulting ophthalmic surgeon. Dr. Robertson was president of the Royal College of Surgeons in 1886; in 1893 and 1894 he was president of the Ophthalmological Society of the United Kingdom. In the latter year he was also president of the International Congress of Ophthalmology which met at Edinburgh. He was surgeon oculist in ordinary in Scotland to Queen Victoria and to King Edward. In 1896 the university of Edinburgh conferred on him the degree of LL.D. Robertson's contributions to ophthalmology were many, and several were of the first importance. In 1863 appeared his paper on the Calabar bean, and in 1869 and 1870 his papers on spinal myosis, in which he described that condition of the pupil which has since been known by his name. He was a first-class operator and an excellent teacher. He was also a good shot, but golf was his chief recreation. In 1904 Dr. Robertson gave up practice and returned to his seat, "Mon Plaisir," in Jersey, dying Jan. 3, 1909, at Gondal, India, while on a visit to the Thakur of Gondal. (*Ophthalmic Review*, February, 1909, p. 59, with portrait. See also abstract in the "Ophthalmic Year-Book," Vol. VII, 1910.)

STAINS DESCRIBED BY GIEMSA AND LEVADITI

To the Editor:—Please give me the formula and the technic for Giemsa's stain and for Levaditi's stain.

LYNN M. BARNES, M.D., Decatur, Ill.

ANSWER.—1. The formula of the Giemsa stain is as follows:

Azur II eosin.....	3 gm.
Azur III.....	0.8 gm.
Glycerin.....	250 c.c.
Methyl alcohol.....	250 c.c.

Smears from chancres, etc., are fixed for ten minutes in absolute alcohol. The preparations are then stained in a dilute solution of the Giemsa stain (made by adding one drop of Giemsa stain to 1 c.c. of distilled water, and rendering alkaline with a few drops of 1 per cent. solution of potassium carbonate) for from two to twenty-four hours or in the undiluted stain for from one-half to six hours. Afterward they are washed in distilled water, dried and mounted.

2. Levaditi's method may be employed for sections: (1) Fix pieces of tissue about 1 mm. thick in 4 per cent. formaldehyd solution, 1 part of liquor formaldehyd to 9 parts water, for twenty-four hours. (2) Wash in water and harden in 95 per cent. alcohol for twenty-four hours. (3) Wash in water for some minutes (until pieces sink). (4) Place in 3 per cent. silver nitrate solution at 37 C. for from three to five days in the dark. (5) Wash in distilled water for some minutes, and then place in the following solution at room temperature for from twenty-four to forty-eight hours:

Pyrogallol.....	2 to 4 gm.
Formaldehyd solution.....	5 c.c.
Distilled water.....	100 c.c.

(6) Wash in distilled water, dehydrate in absolute alcohol, clear in xylol, embed in paraffin, cut, and mount.

PAINLESS INSERTION OF HYPODERMIC NEEDLE—ORIGIN OF TERM "STONE BLIND"

To the Editor:—If the skin of the arm, etc., be carefully inspected, especially after lightly brushing it with the palm of the hand, a minutely mottled pink and white coloration will be noted. The nerve supply of the body is everywhere closely related to the blood-vessels, even to capillary distribution, hence the white blotches are poorest in nerve tissue and therefore least susceptible to pain. If these white areas be the points of choice and the needle be applied perpendicularly to the surface of the skin little or no pain will be experienced.

Referring to the note at the foot of page 848 of THE JOURNAL, September 3, about the origin of the popular term "stone blind," should we not look to a popular source for the explanation of such terms rather than to the medical literature? The lay mind knows little or nothing of glaucoma, but has always been familiar with the eyes of marble statuary that see not, and the sculptured ears of stone that hear not, and the unfeeling rocks in general. Should we not therefore look to this fact for the origin of such terms as "stone hearted," "stone deaf" and "stone blind" rather than to the far fetched suggestion in the footnote referred to?

E. B. KNAPP, M.D., Kansas City, Mo.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Sept. 17, 1910.

Tenney, Elmer S., M. R. C., September 9, granted leave of absence for twenty days, terminated not later than Nov. 3, 1910.

Martha Shelley U., M. R. C., September 9, relieved from duty at Camp of Instruction, Fort Benjamin Harrison, Ind., about Sept. 15, 1910, and will return to his proper station, Fort Des Moines, Iowa.

Bierbower, Henry U., M. R. C., September 9, ordered to proceed to Fort Benjamin Harrison, Ind., for duty with the Sixth Cavalry, at Camp of Instruction.

Schneider, C. R., major, September 9, on the abandonment of Fort Walla Walla, Wash., will proceed to Boise Barracks, Idaho, for duty at that station.

Chen, F. M. C., major, September 9, granted leave of absence for one month.

McLown, Thomas B., M. R. C., September 11, left Fort Barrancas, en route to Fort Dade, Fla., on temporary duty.

Rundesen, H. N., M. R. C., September 11, left Fort D. A. Russell, Wyo., on fifteen days' leave of absence.

Sherwood, John W., M. R. C., September 12, granted twenty days' leave of absence.

Knox, Howard H., lieutenant, September 12, granted 10 days' leave of absence.

Wallup, Joseph O., M. R. C., September 10, granted fifteen days' leave of absence.

Jackson, T. W., M. R. C., September 13, left Fort Hunt, Va., on ten days' leave of absence.

Cullen, Charles W., M. R. C., September 13, ordered to Fort D. A. Russell, Wyo., and granted two months' leave to take effect on arrival at station.

Barlett, William K., capt., September 12, granted five days' leave of absence.

Medical Corps, U. S. Navy

Changes during the week ended Sept. 17, 1910.

Loughbaugh, R. L., P. A. surgeon, commissioned passed assistant surgeon from May 4, 1910.

Donaldson, M., P. A. surgeon, detached from the naval hospital, naval home, Philadelphia, and ordered to duty at the naval hospital, Newport, R. I.

Reed, E. U., P. A. surgeon, detached from the Philadelphia and ordered to the Princeton.

Miller, J. T., P. A. surgeon, commissioned passed assistant surgeon from June 27, 1910.

Castaño, H., asst.-surgeon, detached from the Princeton and ordered to the Philadelphia.

Hermesch, P. A. surgeon, commissioned passed assistant surgeon from July 12, 1910.

McDowell, R. W., asst.-surgeon, discharged from treatment at the naval hospital, Norfolk, Va., and ordered to the Naval Medical School Hospital, Washington, D. C., for treatment.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Sept. 13, 1910.

McIntosh, W. F., surgeon, detailed as member of a Revenue-Cutter Service Retiring Board, Baltimore, Sept. 15, 1910.

Wertenbaker, C. P., surgeon, granted 1 month's leave of absence from Sept. 12, 1910.

Robinson, D. E., P. A. surgeon, granted 1 month's leave of absence from Sept. 8, 1910.

Gwyn, M. K., P. A. surgeon, detailed as member of a Revenue-Cutter Service Retiring Board, Baltimore, Sept. 15, 1910.

Portyjohn, Joseph, P. A. surgeon, granted 1 month's leave of absence from Sept. 15, 1910, on account of sickness.

Warner, H. J., asst.-surgeon, granted 7 days' leave of absence from Sept. 17, 1910.

Priebe, Paul, asst.-surgeon, granted 10 days' leave of absence from Sept. 8, 1910.

Grimm, R. M., asst.-surgeon, leave of absence for 4 days from Sept. 1, 1910, amended to read 4 days from Sept. 13, 1910.

Thompson, Lewis R., asst.-surgeon, directed to proceed to Chicago, and report to the Medical Officer in command for duty and assignment to quarters.

Bingham, E. O., acting asst.-surgeon, granted 15 days' leave of absence from Aug. 16, 1910, on account of sickness.

Horning, Henry, acting asst.-surgeon, granted 7 days' leave of absence from Sept. 6, 1910, under paragraph 210, Service Regulations.

Hume, Lea, acting asst.-surgeon, granted 5 days' leave of absence from Aug. 1, 1910.

Mason, William C., acting asst.-surgeon, granted 7 days' leave of absence from Sept. 18, 1910.

Sinclair, A. N., acting asst.-surgeon, granted 4 days' leave of absence from August 23, 1910, under Paragraph 210, Service Regulations.

Wallace, C. R., acting asst.-surgeon, granted 19 days' extension of leave from Aug. 3, 1910, on account of sickness.

Walkley, W. S., acting asst.-surgeon, granted 3 days' leave of absence from Sept. 16, 1910.

Dr. Lewis R. Thompson commissioned (recess) an assistant surgeon in the Public Health and Marine-Hospital Service, Sept. 6, 1910.

Board of medical officers convened to meet at the marine-hospital, San Francisco, Sept. 21, 1910, for the purpose of making physical examinations of officers of the Revenue Cutter Service. Detail for the board: Passed Assistant Surgeon R. E. Ebersole, chairman; Assistant Surgeon R. A. Kearney, recorder.

Board of medical officers convened to meet at the marine-hospital, Baltimore, Sept. 21, 1910, for the purpose of making physical examinations of officers of the Revenue Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; Passed Assistant Surgeon M. K. Gwyn, recorder.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Thirty-Sixth Annual Meeting, Held at Detroit, Sept. 13-15, 1910

The President, DR. FRANK P. NORBURY, Hospital, Ill., in the Chair

Pain in Abdominal Diseases

DR. WILLIAM M. HARSHA, Chicago: In order to interpret pain properly, a careful history is necessary as pain must be considered in relation to other factors in a given case, and without these it loses its chief importance. The relation of pain to taking food is also of great value, particularly in duodenal or gastric ulcer or the various stenoses, benign or malignant. The direction and extent of painful radiations and the association with hyperesthesia, local tenderness, and muscular rigidity are of great importance as indications of the site and gravity of the lesion. The arm pain in angina pectoris, the shoulder or upward radiation in gall-bladder disease and downward, forward, and testicular pain in nephritic colic are well-known examples. The pain of abdominal disease may be either spontaneous or elicited by pressure, body movement or position, and it may be influenced by psychical, thermic, mechanical or chemical means, all of which may be utilized in cases to aid in exact diagnosis. Diseased viscera cause pain at or near their various sites, but there are many exceptions which lend importance to the reflex or referred pains. A number of abdominal diseases, especially of the more acute variety, are first heralded by pain rather than by change of size, position, or other physical conditions. The surgeon can often gauge the urgency in a given case by the character and severity of pain. Taking cognizance of the value of pain associated with local distentions and peristalsis, or the absence of peristalsis, we may locate stenosis or other forms of obstruction, calling to our aid submerged palpation, or palpation in the bath, which will enable us to detect induration which is otherwise not palpable. By observing the time-relation of pain to other symptoms, the effect of food, drugs, cathartics, cold, fatigue, movement, position, jarring, fist percussion, anesthetics or electric stimulation, we should be able to increase the percentage of correct diagnoses.

The safety of abdominal section may have caused us to relax our efforts at exact diagnosis. It has frequently happened that laparotomy has been done for appendicitis when a movable kidney, pyelonephritis, ureteral stone, typhoid,

diaphragmatic pleurisy, salpingitis, or some other condition is present. Age, sex, occupation, or previous history may give valuable aid. In childhood intestinal troubles prevail, and we are likely to encounter appendicitis, intussusception, or tuberculosis, and in advanced age malignant disease. In women, the pelvic organs are frequent sites of disease, while gall-stones are frequent. Lead colic may simulate organic disease. A history of indigestion, with vague epigastric pain, may aid in determining a perforation of the duodenum or stomach, and a record of previous inflammatory trouble in the abdomen may explain a sudden intestinal obstruction. Among the less frequent conditions may be mentioned the meteorism with abdominal pain, resulting from the embarrassed portal circulation in cardiac insufficiency. I have recently seen a case of this kind in which the pain was so pronounced and distentions so great that abdominal tumor was suspected by one physician. We should consider the possibility of disease of the central nervous system, such as tabes, herpes, or hysteria, disease of the spine, as caries, or spondylitis deformans. We should also consider the possibility of disease of the thorax, referring pain and rigidity to the abdomen; or to one kidney referring the pain from stone to the kidney of the opposite side. Excluding pain from the cord, spine or reflex causes, we should remember that diseased viscera may be at the normal site, displaced especially by prolapse, or transposed. On the surgeon falls the burden of responsibility for exact diagnosis, as his operative experience should add to his knowledge.

DISCUSSION

DR. WILLIAM FULLER, Chicago: The man who can best interpret the significance of pain is the one who has suffered some pain. While I do not think it necessary to have all the acute abdominal diseases in which there is great pain to make a diagnosis, I think a little knowledge gained in a practical way helps out very much. Dr. Harsha's paper contains two excellent points: First, is the emphasis that he lays on the fact that abdominal pains may be severe from trivial abdominal affections; second, is his statement that very serious abdominal affections may be unattended by pain.

DR. CHANNING W. BARRETT, Chicago: When a patient complains of pain generally over the abdomen from appendicitis or gall-bladder trouble, we find frequently by putting the finger on the point that is affected, or supposed to be affected, and making a little pressure that the surrounding pain disappears. We can then go over the rest of the abdomen, and while the patient may complain of local pain, the rest of the pain is gone. An anesthetic is of great value sometimes in pelvic and abdominal cases, but I think we gain more knowledge of these conditions by examining the patient first without an anesthetic.

DR. L. W. BREMERMAN, Chicago: In diseases of the kidney or the ureter, I have seen cases in which there was hematuria, with marked pain over the region of the kidney, the kidney being felt on palpation, excessive tenderness over the kidney, a kidney lesion diagnosed, and surgical intervention recommended. On cystoscopic examination of the individual, I discovered that the hematuria was developing from the supposedly healthy kidney, the urine from the supposedly diseased kidney being normal. Every method of examination should be resorted to before an absolute diagnosis is made.

The Cause and Significance of Tubal Rupture in Extrauterine Pregnancy

DR. CHANNING W. BARRETT, Chicago, read a paper on this subject in which he drew the following conclusions:

1. Pregnancy, which is considered to be always extrauterine in the beginning, assumes pathologic significance when it undergoes ectopic attachment.
2. The ovum attached in the tube has a parasitic action, having a malignant tendency in that it destroys maternal tissues, embeds itself in the tube wall and tends toward death of the mother, but in "making its bed digs its own grave."
3. The growth of the ovum or enlargement of dead ovum mass together with the destruction and thinning of the tube wall leads to almost certain rupture of the tube.
4. The primary rupture may be partial and even slight, or it may be complete and even fatal.

5. If incomplete, a subsequent rupture or ruptures are the rule.
6. With rupture there is free hemorrhage more or less severe, which is never to be looked on lightly and which may prove fatal.
7. The loss of blood may be through one rapid fatal hemorrhage or there may be a series of lesser hemorrhages.
8. If the patient does not succumb to loss of blood the presence of the blood and the ovum in the abdominal cavity act as irritating, foreign substances leading to loss of function and pathological changes in the viscera, and perhaps to local or general infection, thrombosis, embolism, etc.
9. The dead ovum is only slightly less harmful from the standpoint of infection.
10. A study of the pathology makes all treatment looking toward killing the ovum appear irrational.
11. Patients in good condition with or without ruptures are almost certain to have future trouble and should have an operation as soon as is consistent with good work.
12. Patients in bad condition with concealed hemorrhage from the cause in question have collapse in proportion to the amount of blood lost, and rational treatment must look with certainty toward the stopping of further hemorrhage.
13. An opening of the abdomen with clamping or ligating of the vessels is the only reliable means of controlling internal hemorrhage and if done rapidly and with care is little tax on the patient.
14. The clinical experience of the world and a study of the pathology of this condition points to the danger of delay.
15. The more desperate the case while the patient yet lives, the greater the call for immediate action.

DISCUSSION

DR. EDWIN WALKER, Evansville, Indiana: I know of one death from repeated hemorrhages, but most of the deaths have been in delayed cases in which sepsis has occurred after operation. The teaching that we should wait in these cases is not sound. I feel that the position taken by Robb is untenable. These patients who have been operated on promptly in my experience have recovered.

DR. JOSEPH RILEY EASTMAN, Indianapolis: This is 1910, and it is a pity that it is necessary for Dr. Barrett to present a paper like the one he has read. The teaching that it is wise to allow a woman to bleed into her own abdomen, or into her tube or uterus, while the surgeon stands by with his arms folded and falls back on soft pillows or relies on Providence, is absolutely pernicious. If a vessel were bleeding on the surface of her body, what man would be so negligent or so indolent as to stand by and allow the patient to bleed to death?

DR. CHARLES STOLTZ, South Bend, Ind.: I think that the more energy we expend in teaching that these conditions are to be met and not dallied with the better. The men who have received the proper teaching will recognize these conditions, and they will usually find some one who is competent to meet the conditions speedily, or they may be competent to operate themselves, because if there is any delay, or if the patient is carried from one place to another, she may die. I would rather act on the theory that shock is hemorrhage, and hemorrhage is shock.

Special Points in Advanced Extrauterine Pregnancy

DR. SHELBY C. CARSON, Greensboro, Ala.: Although my experience is *nil*, I venture the suggestion that the operation for advanced extrauterine pregnancy be done in two stages when necessary or advisable, at an interval of from 48 to 60 hours, according to the judgment of the operator. In the first place, let the abdomen be opened, the child delivered, and the ovarian and uterine arteries clamped by rubber covered forceps, if they can be approached. In the second stage, separate the sac, release the blood-vessels after ligating the anomalous one, and closing the abdomen. Sometimes hysterectomy is imperative. This differs from and apparently is superior to the old method of uniting the sac to the incision and waiting weeks for its separation, since by this method the danger from sepsis is eliminated.

DISCUSSION

DR. J. H. CARSTENS, Detroit: I had one patient who went to term, a general practitioner having made the diagnosis. I operated on her in two stages. The placenta seemed to be attached to the intestines and the rectum, and I did not have the courage to remove it. I thought the best thing would be to leave the placenta alone, and so I removed the fetus, separated the peritoneum with the sac, and drained. The woman was septic at the time of operation, and finally died

from sepsis. The placenta did not separate. Little shreds came away through the abdominal incision.

DR. W. M. HANSEN, Chicago: I have never heard satisfactorily explained the cause of the intense pain that comes on in cases of tubal rupture. The extent of pain and the broad radiations of it are great in comparison to the very small area apparently involved. A woman with tubal rupture suffers pain from her chest to her thighs—sometimes, at least. The broad radiation with the intense character of the pain make it almost impossible to get from these patients a rational explanation or history. These are the cases in which I believe a good dose of morphin is indicated: First, it will abolish the cardinal or reflex pains to a certain degree and help to localize the trouble; second, it will limit the hemorrhage. Before administering morphin one should observe carefully the character of the pain, the extent of the radiations, the time, and the urgency of the condition. After recognizing these, morphin will answer two indications, namely, to relieve the shock and put the patient in a better condition for operation, and to some degree arrest the hemorrhage.

DR. CHANNING W. BARRETT, Chicago: In dealing with advanced extrauterine pregnancy we find that in the early months the ovum is not considered. The probabilities are that so far as the ovum is concerned it will die, and the chances are that it will kill the woman sooner or later. A few years ago, we would have said that at any time during the extrauterine pregnancy, early or late, the ovum should be removed at the earliest possible time. The teaching has been that if the ovum has passed the fifth month we should wait for viability. I would be inclined yet, even in spite of that teaching, to remove the ovum when found.

Acetabular Fracture With Intrapelvic or Central Dislocation of the Femoral Head

DR. WILLIAM FULLER, Chicago: So close is the relation between fractures and the changes that take place in the bone, whatever they may be, that all such injuries resulting from trivial or slight degrees of violence, or possibly in unusual fractures with greater degrees of violence, should be regarded as possibly belonging to this class. Efforts have been made by several observers to put the etiology of fractures on a physical basis by studying the mechanical capabilities of bone. The great strength of the pelvic bones, their peculiar and powerful articulations and liberal muscular supply, are factors which singly and combined contribute much to the neutralization of all forms of direct violence exerted on this portion of the body. While Katz's theory of the mechanism of certain acetabular fractures will probably hold good, it is also worthy of mention that the experiments of Kusmin demonstrated that this fracture could or would not occur unless the force be applied with the femur in abduction. When the legs were kept parallel the acetabulum remained unfractured. From impacted fractures of the femoral neck central dislocation of the femoral head may be differentiated by the age of the patient and the comparatively high degree of injury in the latter instance. The remarkably sunken appearance of the greater trochanter and its slightly altered relation to Nélaton's line are points which distinguish the dislocation. The certainty with which the femoral head may be palpated in either of the anterior dislocations of the femur and its increase in length in the thyroid dislocation will serve to differentiate any one of these dislocations from a central one. In the dorsal dislocation, especially one above the obturator internus tendon, the trochanter is far above Nélaton's line, the thigh is adducted, flexed, and the axis of the dislocated femur crosses the lower end of the opposite one. Moreover, in the simple dislocation all movements will be less free than when the head and neck occupy a central position. I do not intend that the symptoms of acetabular fracture given here are to minimize in the least the importance of the radiograph, but that each and every manifestation of all hip injuries of whatever nature should be carefully and cautiously considered. In no instance should the clinical findings settle the diagnosis, as they are frequently misleading, and the conclusions based thereon

should invariably be corroborated by the roentgenologist. In case of failure to replace the head of the femur within the acetabulum, operation may offer the only hope of satisfactorily dealing with such a condition; but the particular type of operation and the advantages to be gained by it will depend much on factors opposing the reduction.

Gastrostomy as a Curative Measure per se in Non-Malignant Strictures of the Esophagus

DR. JOSEPH RILUS EASTMAN, Indianapolis: The directly beneficial effects of gastrostomy in cases of so-called benign strictures of the esophagus are not generally appreciated. We have been too slow to break away from old notions, which were developed in the pre-aseptic era when the performance of gastrostomy was attended with considerable danger. Ewald, in discussing a report of successful dilatation of a diphtheritic stricture by Rosenheim, referred to a peculiar observation which he had made in dealing with such benign stenoses, namely, the remarkable circumstance that cicatricial strictures for which gastrostomy had been made nearly always improved steadily after the stomach fistula had been provided and food had been introduced through the fistula instead of through the gullet, that is, the stricture gradually developed a larger caliber without any other treatment whatsoever.

Ewald explained these phenomena in the following manner: After the gastrostomy is made it becomes possible to fill the stomach with food. The pull of the full stomach downward gradually stretches to some degree the elastic esophagus. When the stomach becomes empty the downward pull ceases, then the pressure of the food mass above the stricture has its effect on the stretch and more yielding strictured segment. More compact masses of food may then squeeze through. The explanation of the phenomena given by Ewald can hardly be applied to all cases. After the swallowing of a hot or caustic fluid, the mucosa of the gullet may become deformed in many ways. Among many interesting deforming processes are, for example, the complete tube cast-like separation of the mucous membrane described by Strauss, the esophagitis desiccans superficialis of Rosenberg, and esophagitis exfoliativa. In these conditions after the mucosa has become loosened from the underlying tissues and thrown into folds or ridges or pockets, it is easy to understand that the passage of food or of a bougie must be attended with great mechanical difficulty. It also seems fair to believe that the downward traction due to the filled stomach must have the effect in some instances of smoothing the valve-like folds and irregularities of the loosened membrane, thus permitting the passage of food through a previously impassable esophageal lumen. Gastrostomy is curative per se for another and more important reason. The rest afforded the esophagus is of the greatest value in allaying the inflammation which precedes or attends practically all benign strictures. If ulceration be present, the passage of food, or what is worse, the arrest of food, with consequent fermentation, must maintain or increase the activity.

Fracture-Dislocation of the Atlas and Axis

DR. CARL E. BLACK, Jacksonville, Ill.: Called attention to the essential diagnostic points and gave reasons why operative interference has not been adopted more frequently. He summarized the treatment of such injuries as follows:

Immediate reduction may be done under an anesthetic. Walton has his patient sit in a chair while he turns the head still farther from the dislocated side. The head is then tilted to the sound side and extended while the column is rotated back into place. Hueter's method by rotation may be used. When the atlas is dislocated, before any method of reduction is undertaken, we should be sure that the odontoid process is not fractured. If the odontoid process is fractured, we are advised by some to place the patient in a plaster cast which will immobilize the seat of injury until healing can take place, and then reduce the deformity. The objections to this plan are that it fails to give the patient any opportunity for relief before degenera-

tion of the cord can take place, and subjects him to further pressure from callus, and finally it will usually be found impossible to effect reduction after so long a time. Another plan is operative interference. While considerations of the cord are all important in such injuries, we should not be deterred from making every reasonable effort to restore the dislocated or fractured spinal vertebrae, because many questions regarding the degeneration and regeneration of the cord are in the stage of controversy and remain unsettled. It would seem to be our plain duty to effect a restoration of the bony column as far as it can be done without further endangering the cord, except in those cases in which the cord is hopelessly crushed beyond the possibility of the recovery of lost functions. The mechanical difficulties are great and often insurmountable, but perseverance with reasonable efforts to overcome them will certainly tell in time. It is a reasonable proposition that an injured cord has a better chance in a spinal canal with sufficient room than it has when held under even mild compression. From this reason, the second indication should usually be omitted and the injured parts exposed thoroughly. If the case is one of dislocation, efforts at reduction can be repeated under the direction of the eye and finger, and failing in this a laminectomy may be done.

Preparation Required for the Practice of General Surgery

DR. G. W. GREEN, Chicago: The public has a right to demand of the surgeon (1) a good foundation in the shape of a diploma from a good school; (2) considerable time spent with a master of surgery, so that he has the following knowledge: (a) sufficient experience to make a correct diagnosis; (b) sufficient experience to know what is the best to do when the diagnosis is made; (c) that he shall know just how to do the work and have enough practice to have a definite surgical technic of his own, so that he is capable of performing the operation he essays, or any complication which might arise from that operation, in an average length of time; (d) that his mortality shall be as low, and his postoperative results as good, as those of the average surgeon. In return the surgeon has a right to expect fair remuneration and respect from the public, but no more than any other member with equal qualifications, specializing in any other branch of this, one of the noblest professions on the face of the earth.

Tuberculosis of Bones and Joints

DR. EDWARD M. BROWN, Chicago: The treatment of tuberculous joint disease is (1) general or constitutional; (2) specific or serum treatment; (3) local. For practical purposes the local treatment may be divided into injection treatment, mechanical and operative. The advantages of operative treatment are: 1. The disease can at once be thoroughly eradicated, or nearly so that the patient easily overcomes the disease. 2. Dissemination of the disease is prevented. 3. The treatment is shortened. 4. The general condition of the patient rapidly improves. 5. The length of the limb and function of the joint are preserved to the best possible degree.

The Responsibility of Physicians in the Traumatic Neuroses

DR. H. H. DRYSDALE, Cleveland, Ohio: In studying these conditions etiologically I have arrived at the conclusion that the true genesis, in a large majority of cases, is psychic, and that it is fright, fear of death, anticipated pain and anguish received unexpectedly by a totally unprepared sensorium which is the chief element to be considered. Psychologically, fright is a fundamental emotion. Violent in action, it will under certain conditions of mind pervert the sense faculty, disturb the kinesthetic equipoise and deform the physical and psychical personality. I consider the manifestations of these conditions to be the involuntary expression of a break in the bodily feeling. These by degrees tend to organize and combine to form a morbid mental state, a delusive conception, as it were, toward which every thought converges. A faulty environment frequently does more harm than the actual injury, as it tends to make the individual

introspective and depressed, and as a consequence he throws aside the normal weapons of defense and surrenders himself to the misfortune which has assailed him. From an experience of 108 cases investigated from the standpoint of the corporation as well as that of the patient, and which included in many instances the prelitigation, also the post-litigation period, I have made several observations which I believe, if put into practice, would place the responsibility of adjusting these trying conditions on a scientific basis, and thus obliterate much of the confusion and disquietude which surrounds the traumatic functional disorders of the nervous system.

Hygroma of the Testicle

DR. CHARLES M. HAEPSTER, Toledo, Ohio: A hygroma is essentially a serous cyst. The bacillus of tuberculosis is often found, and the hygroma, if a true one, always contains hard caseous masses and rice bodies. A true hygroma of the testicle and cord is rare. In the case of a man, aged 45, the patient suffered from a hydrocele for a number of years, and this was frequently tapped by his family physician. Some months ago it was tapped and considerable blood and some pus were withdrawn. This alarmed the patient, and in consultation with the attending physician I found the testicle considerably enlarged and very painful, with some slight general disturbance. The cord and testicle were removed. Tubercle bacilli were found in the rice bodies and tissue of the sac. Syphilis undoubtedly had been contracted, but was denied by the patient.

The Tubercle Bacillus Cultivated from Cases of Primary Tuberculous Cervical Adenitis

DR. WILLIAM LITTERER, Nashville, Tenn.: Nine consecutive cases of primary tuberculous cervical adenitis were examined, which resulted in the isolation of five cultures of bacillus tuberculosis of the human type, and the four cultures of the bovine type. The classification of the types being made on the basis of four tests, to wit: First, the morphologic characters of the bacilli; second, the dysgenetic or eugenic characters of the cultures; third, the relative virulence toward rabbits, and, fourth, the reaction curve in 5 per cent. glycerin bouillon. This latter test serves admirably to distinguish between the two types, provided repeated application and careful control over a period, in some instances, of 18 months. I have found that the differences in the growth of the two types dysgenetic and eugenic on Doreet's egg medium to be very valuable in differentiating the bovine from the human type of bacillus. Rabbit virulence has probably been more uniformly satisfactory than any of the tests in determining the differences between the two types of bacilli.

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirty-Eighth Annual Meeting, Held at Milwaukee, Wisconsin,
Sept. 6-9, 1910

(Concluded from page 1046)

SYMPOSIUM ON MENTAL CONDITIONS

The Prevention of Mental Defects and Mental Diseases

DR. WILLIAM A. WHITE, Washington, D. C.: The practical things that may be done at once in any community are these: 1. Legislation should be secured placing the responsibility for the care of the insane previous to commitment in the local health office. 2. Every city of 100,000 inhabitants, or over, should have a psychopathic ward connected with its municipal hospital, which is as accessible for the mental case as the other wards are for general medical and surgical cases. This ward should have an out-patient department. 3. An after-care society should be organized to assist persons who have been discharged from a hospital for the insane to get on their feet and to point out to them ways of avoiding the conditions which led to their breakdown. 4. Adequate laws should be passed for the control of the labor of women and children. 5. There should be a campaign of popular edu-

cation. By the use of this term I am not merely dealing in a glittering generality that may mean nothing or everything. We have in this country nearly 200 state hospitals for the care of the insane. Each of these hospitals should be a center of information for the community in which it exists, and its medical officers should use their positions to spread information about mental disorders. The superintendent, or a member of the staff, should deliver one or more popular lectures each winter to which the public should be invited. Much might be accomplished in this way if all hospitals would do this. 6. Field work should be carried on from the state hospitals and psychopathic wards as centers to study conditions under which insanity has developed, to furnish assistance to the hospital in dealing with its patients, and to cooperate with the after-care society. 7. More liberal support should be given by city and state for scientific research work in this field, especially along the lines of etiology and prophylaxis."

Prevention of Feeble-mindedness

DR. E. R. JOHNSON, Vineland, N. J.: Two or three states have passed laws authorizing the unsexing of degenerates after they get into institutions, but please note that these individuals must get in the institutions first. I heartily approve of the operation of castration and merely agree to vasectomy and salpingectomy. After these operations have been performed a fair percentage of the patients may be returned with safety to their homes, and thus make room for others in the institutions, but the ideal way is to gather all the feeble-minded into institutions, and train them in so far as possible to be self-supporting—plenty of industrial occupation and very little academic training. From 30 to 50 per cent. can be made entirely self-supporting after 10 years' training. Take the women of child-bearing age first and teach them to raise and can small fruits, raise poultry and garden truck, knit underwear, weave rugs, carpets, etc. Then take the others as young as possible and the economic problem comes close to solution. But do not talk—get to work. The numbers are increasing. If they are not cared for in well-conducted training schools, where they may learn to contribute toward their own support, they must be kept in almshouses, reformatories, prisons and other institutions, and when they are led into evil ways the taxpayers pay for their arrest, their trial and the damage they have done. If feeble-mindedness is to be checked, physicians personally must do something.

Preventable Neuroses

DR. C. H. HUGHES, St. Louis: I wish to speak about the prevention of the neuroses which underly the physical, the moral and the mental integrity of the people, and which, if not considered and timely regarded, will eventuate in degeneration and degradation of our people, such as have visited the people who have gone before. The neuroses constitute the bane of our civilization. It was the neglect to care for a neurosis that caused the greatest of human generals to fall. It was a neglected epileptoid condition that caused Napoleon Bonaparte to lose the battle of Waterloo. As physicians we are for prevention of the neuroses, those conditions of mind and of the nerve centers that have so much to do with the individual in the community, with the individual on the firing line in the battle of life, and with the individual who has to meet the duties and obligations of our modern civilization, with its strenuous demands, in order to conserve the vitality of the race and save America. We must prevent neuroses because they are the bane of civilization; they are the bane of the family life; they are the bane of social life. The incongruities and unhappiness that exist in families and revealed so largely in the divorce courts are the product on one side or the other, and often on both, of the dominance of the neuropathic element in one or the other, or both members of the family. Lawyers speak of incompatibilities, but these individuals are instances of neurotic ill-adaptability. They are psychical misfits. By neuroses I mean not alone functional conditions of the nervous system, because the line of demarcation between functional and organic disease is only a question of time and of study

and further observation, but the functional affections of yesterday which are the organic troubles of to-day. The time is coming when we will understand hysteria to be an organic disease. Insanity comes down to us in its predisposing element in the majority of instances as an inherent predilection, an inherent organic tendency, and superadded to it comes the disturbance or influence of environment, the disturbing influences of depressive passion, the influences of conditions of over-strain, over-worry, which over-annoy the human mind. We should have a reasonable regard for the powers of the growing child, so that he may not be over-strained. He should have an adequate amount of fresh air, abundant nutrition, ample time for rest; and the prevention of those conditions which come from excesses is the cardinal principle which underlies the prevention and evolution and final destructive development of all neuroses.

Discussion on Mental Conditions

DR. JOHN N. HURTY, Indianapolis: What if we do save a child from diphtheria or scarlet fever, and yet fail to save it from some neurosis. The child is lost just the same. The longer I live and work in the science of hygiene, the more I am convinced that it is hopeless to work with the adult. We must go back and instruct the child; that being done we have taken the first step. Under our present form of education we do not do that except to a limited degree. The thought is gradually penetrating our minds that the child must have playgrounds and fresh air. We have been shutting out the air from the school room and calling it economy. We have been buying sites for school houses without playgrounds, and calling that economy, and it is the worst kind of extravagance. Something must be done to prevent the building of insane asylums, taxing the people, raising the rates, and having insane on every hand, and the way to do this is to begin with the child.

DR. HENRY A. NORDEN, Sturgeon Bay, Wis.: Aside from trying to make a living in the practice of medicine, I have been riding a hobby—the education of children. Neurotic conditions are superinduced by night studies on the part of children. Do not blame the teachers; do not blame the school board, but blame the people who are behind them and have them prevent the school board from doing what they should do. It is absolutely necessary, considering the way education is carried on to-day, for the child to study at night or to sacrifice the playtime of the day. It is almost impossible for children to study in school while one section of the school room is reciting. I have suggested frequently in my work that the number of hours of school sessions be cut down; that we use the school session for the recitations and explanations, and allow a part of the day to be used for pleasure and part for study. In that way we can prevent neurotic conditions that are produced by night studies.

DR. E. C. ROGERS, Faribault, Minn.: Wherever there is a family with two feeble-minded children, that family ought to be studied carefully, its ancestry gone into, and the mental condition of these children studied carefully, and from the work that is now being carried on we hope to have data which will give us the facts necessary to make statements as to what shall be done toward prevention of feeble-mindedness.

SYMPOSIUM ON VENEREAL DISEASES

Report of Committee on Education of the Public as to Communicability and Prevention of Gonorrhea and Syphilis

DR. GEORGE M. KOBER, Chairman, Washington, D. C., presented this report which contained several recommendations, which were referred to the executive committee for consideration, and which were reported back to the general meeting subsequently in the following amended form: The committee recommends:

1. The recognition, study and control of the prevalence of these, as with all other communicable preventable diseases, in order to ascertain their distribution.

2. An educational campaign for parents of all social classes, and children of all ages and sexes. This teaching should be not only moral, but also medical in the widest sense.

(a) Proper distribution of circulars, pamphlets and other literature by state health departments through all suitable channels.

(b) State health departments to instruct all of its local health officers in sexual matters, and direct them to make a special effort to educate the people in their respect.

(c) State health departments to make a special effort to awaken and interest the medical profession in this fight against venereal diseases.

(d) State health departments to send out specially trained paid teachers and lecturers of their own, supported by exhibits and lantern slides to address special meetings of parents, health officers, medical men, teachers and others in schools, colleges, churches, etc., on these and other preventable diseases.

(e) State health departments to encourage the organization of local leagues or associations whose purpose shall be the support of and control of a crusade against the spread of all communicable diseases. Said societies to include every profession and walk of life; to depend on philanthropists for necessary funds, rather than on paid subscriptions for fundamental support.

(f) Health departments to interest and provide for the authorities having charge of the educational curriculum in public and in private schools. (1) By introduction of biology into the graded courses of all schools; (2) To provide instruction in sexual matters for students of the upper grades; (3) by special instruction to normal school students who are to become the instructors. To improve preceptors, and teachers the necessity on students in reference to the common venereal diseases, and to inculcate a morale of protection among the college fraternities.

(g) To utilize the public press for the proper occasional presentation of the subject, and to discourage the display of advertising matter which encourages the exposure to dangers in these diseases.

(h) To utilize church clubs, fraternal societies, trade unions, women's clubs, and especially mother's clubs for instruction of parents.

(i) Health departments to recommend the enactment of laws for: (1) Physical inspection and segregation of prostitutes. (2) Notification and report (by number, if desired) of venereal cases. (3) Physical examination of men before marriage, male applicants for marriage license in order to obtain it being required to submit to an examination by a duly qualified physician for the purpose of ascertaining whether said applicants are free from venereal diseases. 4. To make it a crime to spread any venereal disease. 5. By keeping open free night dispensaries and maintenance of special dispensaries and hospitals for these diseases.

(j) Advocacy of temperance on account of the relationship between alcoholism and venereal diseases.

(k) Advocacy of personal cleanliness and venereal prophylaxis. Advocacy of early marriages.

These recommendations were adopted.

Venereal Diseases Among Seamen of the Merchant Marine

DR. J. W. KERR, Washington, D. C.: There were treated 1,281,427 cases of sickness from all causes, or an average of 53,392 patients annually. Of the total number, 106,090 were cases of syphilis in one of the three stages, 4,420+ being the annual average; 117,336 cases of gonorrhea (including gleet), representing an annual average of 4,889 cases; and 39,819 were cases of chancre (including ulcer of the genitals), or an average annually of 1,659+ cases. The total number of venereal cases treated and classified as above during the period mentioned was 263,245, or an average annually of 10,969 cases. It will thus be seen that these venereal cases represented 20.5 per cent. of the total number treated. This percentage it will be understood represents cases of syphilis, gonorrhea and chancre, and does not include complications or sequelae of those diseases.

Plea for Application of Methods of Preventive Medicine to Venereal Disease

DR. J. R. KEAN, Washington, D. C.: I do not think that it is either wise or necessary for scientific men interested in the good of the race and of the country to take any part in the discussion of the relation of this evil to society. The prostitute is a present confrontation of the problem. There is no reason to think that these diseases are beyond the reach of preventive medicine any more than other contagious diseases, and their immunity from restriction, must be attributed to the public disinclination to discuss them and legislate concerning them. I hope that this association will not be deterred, by the outcry of certain classes of persons who are accustomed to think with their emotions rather than their brains, from taking the bold stand in this matter which is justified by science, by common sense, and by the demands of the public good.

Venereal Prophylaxis in the U. S. Navy for the Benefit of Public Health Officials

DR. CHARLES N. FISKE, Washington, D. C.: About 50 per cent. of the enlisted men of the Navy have a venereal disease during an average of 4 years. During 1908, there were 4,651 original venereal infections which entailed a loss of service

and expense for treatment of 106,526 sick days; there were 1,001 cases of syphilis which represented nearly 7 per cent. of the total physical disability of the Navy for that year. While the morale has steadily and vastly improved during the past 10 years in other respects the damage resulting from this class of affection had assumed such proportions 4 years ago that numerous medical officers no longer felt justified in waiting indefinitely for moral regeneration; they felt that military efficiency demanded activities promising more immediate results; they instituted personal prophylaxis by the use of antiseptic irrigation and injections following exposure and on return to the ship or station. Certain results achieved caused the Navy Department nearly 2 years ago to authorize the extension of this work in connection with the customary educational propaganda, and distribution of confidential circulars throughout the service. Sailors and marines do not contract venereal disease from the navy, but from civil communities which are as notoriously indifferent to venereal disease as they were formerly to typhoid and other widespread infections. Military services have practiced compulsory notification of venereal disease for years and expect civil authorities to undertake similar measures for control. The source of the Navy's 15,000 first enlistment recruits, and the destination of a similar number of men discharged each year, is the civil population; its statistics would indicate that one youth out of every 6 in our urban population between the ages of 17 and 24 contracts a venereal infection each year. Venereal disease has by no means yet been conquered in the Navy, but there is evidence that its ravages are being materially lessened, and that instead of encouraging vice through the hope of immunity, the margin of failure of this prophylaxis is sufficiently wide to deter an increasing proportion of the personnel from sexual indulgence. The desire for clean men on clean ships has been stimulated, and no sense of security has been engendered.

Discussion on Venereal Diseases

DR. GARDNER T. SWARTS, Providence, R. I.: Last year, as president of this Association, I took the liberty of appointing a committee to take up the subject of venereal prophylaxis, with the idea that the people of our country were prepared to receive instruction in these matters. These communicable diseases are preventable, and if boards of health are to conserve the public health, then these diseases should be put on the reportable list and steps taken to prevent their prevalence as far as possible.

DR. J. S. NEFF, Philadelphia: I think that it is not possible to compel physicians to reveal the existence of these diseases among their patients, and they will not report such cases to health departments.

DR. JOHN N. HURTY, Indianapolis: I believe that the road leading to the prevention of venereal diseases is the longest and roughest which hygiene and sanitary science has to travel. At this time, every tribe, every nation, and people of the earth are thoroughly syphilized. Think of that, and now we are proposing to eradicate it. The first man to propose education to eradicate these diseases was Solomon, and he began 5,000 years ago, and with education, such as he gave, and such as we propose to give, these diseases have increased and multiplied. Until we put aside that prudery which now prevents us from attacking this problem correctly, and which prevents us from teaching the child about his sexual nature and procreation, we can make no progress. Let us begin with the child.

Remarks by Colonel Theodore Roosevelt

Col. Theodore Roosevelt, who was unable to address the Association at the Auditorium, as expected, went out to Whitefish Bay in an automobile, and addressed the Association there. He said in part: I regret very much that I was unable to meet you this morning. I could not do so, as the schedule mapped out for me was three times as much as I could do. Like any other man in public affairs, I am awake to the needs of the public health. It is necessary to join our efforts for the preservation of the public health.

It is important not only to keep the health of the individual, but also to keep the health of the nation. Yellow fever is a distinctive national problem. Several nationalities in the western hemisphere have dealt with it and must deal with it effectively to prevent the ravages of this scourge. The question of dealing with the public health is a matter of the last two generations. Half a century ago comparatively nothing was known of diseases which were a scourge to the human race. About 600 years ago the black death desolated Europe, a disease which undoubtedly we could deal with now. Then it took off two-thirds of the population of Europe. I have just come from a trip to the middle of Africa, where disease ravages mankind as it did our ancestors. I passed through regions where the sleeping sickness has to its credit over 200,000 deaths in one neighborhood.

The advances made in the medical profession during the last half century are incalculable. The work on the Isthmus of Panama could not have been done in its present shape a decade ago. The authorities could not have grappled with disease as they do now. The prime requisite in every nation is to have every man and woman an effective unit. You are dealing with the basic problem of citizenship. Men cannot be good unless they are healthy.

I welcome to this convention the delegates who come from foreign countries, especially from the Americas. In the two Americas we are solving the problem of living peacefully together. Our only rivalry, far different from Europe, is the endeavor to see which is best able to cope with the problems that confront us all. I welcome you as our rivals, who are doing all in your power to uplift and care for the physical well-being of the human race.

Disappearance of Yellow Fever from the Mexican Republic

DR. E. LICEAGA, of Mexico City, contributed a paper in which he stated that from the twentieth of December, 1909, not a single case of yellow fever had been observed either there or in any other part of the Mexican Republic. In spite of the success obtained, the sanitary service continues its action with the same regularity as in previous years, although it is now directing its energies especially against malaria.

Quarantine or Isolation in Diphtheria

DR. JAMES ROBERTS, Hamilton, Ont.: I wish to call attention to the dominance of the personal contact factor in the spread of this disease. Defective drains, bad ventilation, etc., although prejudicial to health, cannot cause diphtheria which is due to the presence of certain bacteria. Overcrowding assists the spread of diphtheria; 45 per cent. of my cases, representing not more than one-quarter of the school population, come from the districts where the industrial classes are centered. The presence of an ignorant foreign element hinders the work of sanitation and favors the spread of disease. Diphtheria, owing to the manner by which it is spread, is a school disease. The Boston board of health, after an exhaustive investigation, concluded that it would be impracticable to isolate bacillus carriers who did not themselves suffer from the disease, as these constitute 1 per cent. of all healthy school children, and these germs are ordinarily of little virulence. The restriction of this disease is for practical purposes limited to isolation of clinical cases and control of the contacts in connection with these. When isolation cannot be strictly carried out at home, hospitalization is the best method. But isolation hospitals are very unpopular, owing to their usually poor equipment, the danger of cross infection, etc. They safeguard the community, but often at the expense of the individual. Our present day conception of diphtheria as pre-eminently a school disease makes it imperative that the inspection of school children should be thorough enough for the detection of early cases, and of those children harboring virulent bacilli. When this has been accomplished, regulations intelligently enforced providing for the proper isolation of all cases, either at home or in suitable institutions, will be productive of better results and much less annoyance and hardship than the continued enforcement of antiquated laws and regulations incompatible with our present knowledge of diphtheria.

The Ventilation of Sleeping Cars

DR. T. R. CROWDER, Chicago: The only available method of accurately estimating the air supply of running cars is by determining the amount of carbonic acid gas which their atmosphere contains, and from this computing the amount of air which enters. The problem is mathematically simple, and rests on the known amount of carbonic acid thrown off by respiration. This method has been applied in the study of sleeping-car ventilation. About 2,000 samples of air have been analyzed from these cars. It shows that an average of approximately 40,000 cubic feet of air is supplied hourly to the main sleeping compartment of standard cars, which are equipped with the ventilating system now in common use by the Pullman Company, and that the amount is rarely, if ever, under 20,000 cubic feet. There are rarely more than 20 people in a sleeping car; hence each person is supplied with about 2,000 cubic feet of air each hour. This applies to the findings in occupied berths, both lower and upper, as well as to the car in which the berths are not made up. The high wind pressure to which running railway cars are subjected results in fair ventilation even when they have no special ventilating devices. The amount of air which they receive will vary from 15,000 to 50,000 cubic feet an hour, depending on various conditions.

When cars are uncomfortable and feel "stuffy" the fault is not generally to be laid to an inefficient air supply, as is commonly supposed. It rarely happens that the air supply is so inadequate to bring about this condition, though it may at times contribute to it. The fault generally lies chiefly in an improper control and regulation of the heat supply. The degree of humidity of the atmosphere is also an important factor; but its control is difficult, and often impossible. In my opinion, heat control is a more important problem in maintaining comfort in sleeping cars than is the furnishing of a greater air supply; and relatively greater attention should be concentrated on this element of the problem of maintaining a hygienic atmosphere in cars.

Owen Bill Endorsed

The Association endorsed the principles embodied in the Owen Bill for the establishment of a national department of health.

New Sections

Two new sections, the Section on Sociology, and the Section on Sanitary Engineering were formed.

Resolutions Adopted

INSTRUCTION IN HYGIENE AND SANITATION

A resolution was adopted recommending that a committee be appointed to consider and report next year a scheme (of which Dr. Probst shall be chairman) for instruction in hygiene and sanitation in high schools, and in colleges and universities, with the view to bringing the necessity for such instruction with definite recommendations to the attention of educational authorities. Other resolutions were adopted as follows:

TERMINAL DISINFECTION

WHEREAS, A considerable number of municipal health officers believe terminal disinfection at the conclusion of communicable disease is of questionable value and extravagant in practice; and

WHEREAS, A few municipal health officers of sound judgment and highest attainment have abandoned this practice as a prophylactic measure; therefore, be it

Resolved: That the Municipal Health Officers Section refer to the executive committee a recommendation that the American Public Health Association appoint a committee to study the end results and practice in communities where terminal disinfection is no longer practiced at the conclusion of cases of communicable disease.

COOPERATION WITH CENSUS BUREAU

Resolved: That this Association appoint a committee to cooperate with the Bureau of the Census in establishing standard methods of accounting for municipal sanitation.

INSTRUCTION OF CHILDREN IN SEXUAL MATTERS

Resolved: That this Association offers and accords its hearty approval and commendation of the educational work carried on by the *Ladies' Home Journal* regarding the necessity and ways of teaching children the truth about reproduction and the sexual life.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

An Overcrowded Profession in Nevada

A Nevada correspondent writes regarding the proportion between physicians and population as given in the Educational Number of THE JOURNAL:

"In this state about thirty-five new physicians locate each year, with little or no increase in the population and no likelihood of there being much increase. These new men usually 'go broke' in a short time. Those of us who are here, and who are not crowded out by the new men who are able to stay, have all that we possess invested in property and consequently are unable to leave. Of course, there are exceptions, as some have made investments which have been good ones, but the fact remains that few physicians here are out of debt and physicians are not looked on at the stores as good credit. Many eastern physicians read the boom accounts of some mining camp and think that there are splendid openings in Nevada, but long before they get here, the place may have dozens of roving physicians who have located there. Ethics do not count for much in these new towns. If a doctor gets a contract with a mine for a year, he seldom gets it renewed, as the competition for the place is so keen that some other physician underbids him. The fact that physicians will look for desirable locations where the population is the lowest and the health is the best speaks volumes for the lack of business sense displayed by the average physician. The fact remains that new physicians arrive here at the rate of about thirty-five a year in a state with a population of only about 40,000. What would you think if thirty-five new doctors located each year in a town like South Bend, Indiana? Yet the total population of the state of Nevada is not much greater than that of South Bend, while health conditions are naturally much better."

Our correspondent calls attention to a serious situation. A state with as small a population as Nevada (42,325, according to the 1909 estimate) and with this population widely scattered, can support only a limited number of physicians. Each new arrival means increased competition and more difficult conditions for all. The proportion of physicians to population in the United States is one to 655—if we count only those legally entitled to practice and in active practice—while in Nevada the relative number of physicians is nearly three times as great, there being one to every 239 inhabitants. These conditions make it almost impossible for newcomers to hope for success or even for a living. The facts should be kept in mind and local conditions carefully considered by young physicians before deciding on a location, for Nevada is by no means the only place that is overcrowded, so far as physicians are concerned.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course. Several weeks' programs are given in this issue so that hereafter the programs may appear from week to week well in advance of the time for their use.]

First Month—Third Weekly Meeting

CONGENITAL SYPHILIS

1. **DYSTROPHIES SYPHILITIC IN ORIGIN:** Syphilitic stigmata. Small child, slight resistance to diseases, subject to rickets. Asymmetry of skull, microcephaly, flat nose, palate. Spinal deformities, dactylism, flat-foot, luxation of hip. Aural and ocular defects. Retarded mental development. Idiocy. Malformation of teeth.
2. **EARLY CONGENITAL SYPHILIS:** Time of onset of symptoms. Coryza, facies, saddle-nose, rhagades, anemia. Cutaneous lesions, macular eruptions, psoriasisform syphilide, mucous patches, pemphigus neonatorum. Nails. Hemorrhage.

Bony changes, skull, pseudoparalysis of Parrot, osteochondritis syphilitica. Involvement of liver, spleen, testicle.

3. LATE CONGENITAL SYPHILIS: Age at onset. Earlier manifestations. Development, infantilism. Teeth. Keratitis, chronic otitis. Nose and palate. Skin lesions, gummata and ulcers. Bone lesions, lymph nodes.

Fourth Weekly Meeting

DIAGNOSIS OF SYPHILIS

EARLY: Microscopic diagnosis, *Spirochæta pallida*, primary and secondary lesions.

LATE: Previous history, scars, discolorations of skin, alopecia, bone nodes, frequent miscarriages.

SERUM DIAGNOSIS: Wassermann reaction, theory, technic. Noguchi modification. Value of reaction, occurrence in different stages of syphilis, in other diseases, prognostic value.

THERAPEUTIC TEST: Value of antisyphilitic treatment in obscure conditions.

TREATMENT

PROPHYLAXIS: 1. Control of prostitution. 2. Control of the syphilitic, by reporting the disease, by providing hospital, by vaccination. 3. Legal measures, regarding marriage, occupations, "private-disease" quacks. 4. Education of the medical profession, of the public. 5. Personal prophylaxis. 6. Prophylaxis of hereditary syphilis.

ABORTIVE TREATMENT: 1. Excision or cauterization of the chancre; practical value of each. 2. Constitutional abortive treatment.

CONSTITUTIONAL TREATMENT: Methods of treatment; expectant, interrupted, continuous. 1. Mercury. Physiologic effects. Administration by ingestion, inunction, injection, fumigation, baths and plasters; advantages and disadvantages of each.

2. Potassium iodid. Physiologic action of iodine. Therapeutic effects. Methods of administration, preparations, dosage, untoward effects. 3. Mixed treatment. Indications, advantages. 4. Serum treatment.

TREATMENT OF LOCAL MANIFESTATIONS: 1. Chancre. 2. Skin and mucous lesions. 3. The eye.

GENERAL TREATMENT: Diet, hygiene, etc.

Monthly Meeting

Etiology and Early Diagnosis of Syphilis.

The Methods of Treatment of Syphilis.

Syphilis as a Factor in the Social Life of the Community.

REFERENCE BOOKS FOR THE FIRST MONTH

Works on "Syphilis," by Keyes, Hutchinson, Fournier, and Power and Murphy.

Morrow: Genitourinary Diseases, Syphilology and Dermatology. Haugs and Hardaway: Genitourinary Diseases, Syphilis and Diseases of the Skin.

Taylor: Genitourinary and Venereal Diseases.

Second Month—First Weekly Meeting

General Subject for the Month: Diseases of the Blood-Vessels

ANATOMY

ARTERIES: Gross anatomy, size, shape, course, anastomoses, terminal arteries. Microscopic anatomy, the three coats, vasa vasorum. Lymphatics and nerves. Arterioles.

CAPILLARIES: Structure, size.

VEINS: Histologic structure; anastomoses; sinuses.

PHYSIOLOGY

VELOCITY of blood flow in arteries, veins and capillaries, methods of determination, variations in flow and causes.

BLOOD-PRESSURE: Methods of determination, the sphygmomanometer. Arterial pressure, systolic, diastolic and mean. Capillary pressure. Venous pressure. Production of normal pressure: (1) heart beat, (2) resistance to blood-flow, (3) elasticity of arteries, (4) quantity of blood. Effect on blood-pressure of variations in each of above-named factors. Effect of muscular efforts; of respiratory movements.

THE PULSE: Pulse wave, velocity, form of wave, sphygmograph, anacrotic and catacrotic limbs. Pulse wave in health and in disease. Venous pulse.

VASOMOTOR NERVES

VASOCONSTRICTORS: Origin, center in medulla, course, general distribution, tonicity. Vasoconstrictor reflexes, pressors and depressors.

VASODILATORS: Origin, general course and distribution, properties. Vasodilator reflexes.

REFERENCE BOOKS FOR THE SECOND MONTH

Habeck: Diseases of the Heart and Arterial System.

Miles: Human Blood-vessels.

Russell: Arterial Hypertension, Sclerosis and Blood-pressure.

Janeway: Clinical Study of Blood-pressure.

Text-books on Practice of Medicine and on General Surgery.

Second Weekly Meeting

DISEASES OF THE ARTERIES

ARTERIOSCLEROSIS

ETIOLOGY: Age, sex, occupation, hypertension, syphilis. Chronic intoxications, mode of living, renal disease. Role of poisons in production of arteriosclerosis. Relation between arterial and kidney lesions.

PATHOLOGY: 1. Nodular form. Gross and microscopic changes. 2. Senile form. 3. Diffuse arteriosclerosis. Frequency with which different arteries are involved. Involvement of visceral arteries. Sclerosis of veins.

SYMPTOMS: Increased blood-pressure, thickening of arteries, hypertrophy of heart, change in heart sound. Cardiac symptoms, due to involvement of coronary arteries. Cerebral symptoms, transient paralysis, aphasia, vertigo, hemorrhage, cerebral degenerations. Renal symptoms. Arteriosclerosis of the splanchnic region. Sclerosis of arteries of lower limbs, intermittent claudication.

TREATMENT: Prophylactic, diet, exercise, habits. Curative, physiologic and therapeutic actions of iodine, mode of administration.

SYMPTOMATIC: Vaso-dilators, purgative, venesection, etc.

State Boards of Registration

COMING EXAMINATIONS

ARIZONA: Phoenix, October 3-4. Sec., Dr. Ancil Martin.

COLORADO: The Capitol, Denver, October 4. Sec., Dr. S. D. Van Meter, 1723 Tremont Place.

GEORGIA: Regular, The Capitol, Atlanta, October 11. Sec., Dr. I. H. Goss, Athens; Homeopathic, Atlanta, October 3. Sec., Dr. R. E. Hinman, 153 Whitehall Street.

IDAHO: Boise, October 4. Sec., Dr. O. J. Allen, Bellevue.

ILLINOIS: Coliseum Annex, Chicago, October 19-21. Sec., Dr. James A. Egan, Springfield.

KANSAS: Topeka, October 13. Sec., Dr. H. A. Dykes, Lebanon.

LOUISIANA: New Orleans, October 18-19. Sec., Dr. A. B. Brown, 108 Baronne Street.

MICHIGAN: Lansing, October 11-13. Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit.

MINNESOTA: State University, Minneapolis, October 4-6. Sec., Dr. W. S. Fullerton, St. Paul.

MISSISSIPPI: Jackson, October 11-12. Sec., Dr. S. H. McLean.

MONTANA: The Capitol, Helena, October 4. Sec., Dr. William C. Riddell.

NEW JERSEY: State House, Trenton, October 18. Sec., Dr. H. G. Norton.

NEW YORK: Albany, September 27-30. Chief of Examinations Division, Dr. Charles F. Wheelock.

NORTH DAKOTA: Grand Forks, October 4-6. Sec., Dr. H. M. Wheeler.

OKLAHOMA: Muskogee, October 11. Sec., Dr. Frank P. Davis, Enid.

RHODE ISLAND: State House, Providence, October 6. Sec., Dr. Gardner T. Swarts.

WYOMING: State Capitol, Cheyenne, October 12-14. Sec., Dr. S. B. Miller, Laramie.

West Virginia July Report

Dr. H. A. Barbee, secretary of the West Virginia State Board of Health, reports the written examination held at Charleston, July 11-13, 1910. The number of subjects examined in was 9; total number of questions asked, 120; percentage required to pass, 80. The total number of can-

didates examined was 67 of whom 48 passed and 19 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Louisville.....	(1910) 80, 83, 83, 84, 85, 86, 90		
Johns Hopkins University.....	(1910)		86
University of Maryland.....	(1910)		82
College of Physicians and Surgeons, Baltimore.....	(1910) 80, 82, 82, 82, 83, 83, 83, 83, 84, 84, 84, 85, 85, 86, 87, 90.		
Baltimore Medical College.....	(1908) 85; (1910)		85
Maryland Medical College.....	(1910) 80, 81, 86		
Barnes Medical College.....	(1910)		85
Cornell University Medical College.....	(1910)		86
North Carolina Medical College.....	(1910)		81

College of Physicians and Surgeons, Chicago.....	(1910)	78
University of Louisville.....	(1908) 67; (1910) 74, 75, 75, 78, 78, 78, 79.	
College of Physicians and Surgeons, Baltimore.....	(1910) 76, 77, 77	
Eclectic Medical College, Cincinnati.....	(1910) 71, 74, 75	
Meharry Medical College.....	(1908) 77; (1910)	74
Chattanooga Medical College.....	(1903) 77; (1910)	77

The following questions were asked:

OBSTETRICS AND GYNECOLOGY

1. What forms of hemorrhage are met with before, during or after labor, treatment of each? 2. Define puerperal eclampsia and give its treatment. 3. Name the source, character, relative quantity, and functions of the liquor amnii. 4. What are the most serious complications met with in How would you treat a case of hour-glass would you treat a case of face presentation? treat a case of gonorrheal conjunctivitis in an infant? 8. Give five causes of metrorrhagia. 9. Give in full your treatment of gonorrheal endometritis. 10. Give symptoms and treatment of cystitis.

PRACTICE OF MEDICINE AND PEDIATRICS

1. Give the diagnosis and treatment of acute follicular tonsillitis. 2. What is the practical import of hematuria, and how can its source be diagnosed? 3. Give the etiology and treatment of St. Vitus' dance. 4. Give the symptoms indicative of impacted gallstone. 5. Give some suggestions for diet after weaning and the feeding of children between the ages of one and two years. 6. State some rules regarding bathing, exercising and clothing infants. 7. Describe and treat infantile syphilis. 8. Differentiate pneumonia from capillary bronchitis, give treatment of each. 9. Thrush: State conditions that favor its development. Give treatment. 10. What diseases in infancy usually precede congestion of the brain? Give necessary precautions to prevent.

CHEMISTRY AND MEDICAL JURISPRUDENCE

1. Explain the following terms: atom, molecule, oxidation, reduction, analysis, synthesis. 2. Write the formulas for calomel, bichlorid of mercury, nitrate of silver, copperas, saltpeter. 3. What are the source, properties and uses of quinin, strychnin and cocaine? 4. Name any five organic acids and give their source and uses. 5. Distinguish between wood alcohol and grain alcohol as to their properties and uses. 6. Explain the chemistry of respiration. 7. What are the sources and properties of phenol (carbolic acid)? How would you treat a case of phenol poisoning? 8. Define insanity and give some of its various forms. 9. What is senile dementia? 10. What is the hydrostatic test and what is its value in a case of suspected infanticide?

ANATOMY AND EMBRYOLOGY

1. Into what classes are the bones divided and give a few instances of each. 2. Describe the antrum of highmore. 3. Trace a drop of blood from the tip of the tongue to the index finger. 4. Name the lobes and fissures of the brain. 5. Describe the solar plexus nerves. 6. Describe the stomach. 7. Name the abdominal viscera. 8. Describe the aorta and name its branches. 9. What changes take place in the vascular system at birth? 10. Describe the embryo at end of six weeks of gestation.

SURGERY

1. Describe the treatment of a bullet wound of the leg. 2. Define thrombosis; embolism. Describe the symptoms of venous thrombosis of the leg. 3. Treat a compound comminuted fracture of the middle third of femur. 4. How would you distinguish between a fracture at the neck of the femur without impaction and a dislocation? 5. Burns: Define, classify; give prognosis and treatment. 6. Give the nature and treatment of Potts' fracture. 7. Name the dangers and give the treatment of carbuncle. 8. What is hemorrhage? Divide anatomically and clinically, treat mechanically and therapeutically. 9. How would you determine that a limb was injured beyond hope in a crushing accident. 10. Give the cause and treatment of varicose ulcers.

BACTERIOLOGY AND HYGIENE

1. What are pyogenic bacteria? 2. Define germicide, antiseptic, asepsis, sterile, disinfectant. 3. Define immunity. What is natural immunity, acquired immunity, inherited immunity? 4. How is diphtheria antitoxin obtained? What is the usual dose? 5. What disease is transmitted by a bite of the infected *Stegomyia fasciata*? 6. How do forests benefit public health? 7. Give six desirable factors in the location of a tuberculosis sanitarium. 8. What four diseases may be acquired from drinking cow's milk? 9. What objections are advanced against vaccination? 10. Name five good disinfectants and give indications for their use.

MATERIA MEDICA AND THERAPEUTICS

1. What are antiseptic remedies? Name three and give indications for their use. 2. What are excitomotors? Name three and explain therapeutic action of each. 3. Give two cerebral sedatives and give therapeutic action. 4. Aconite: Physiologic action. Therapy and dose of tincture. 5. Apomorphin: From what derived, physiologic action, therapy and dose. 6. Nitroglycerin: Give properties, physiologic action, therapy and dose. 7. Digitalis: Dose and indications for use. 8. Name three emetics with dose of each. 9. Ferrum: Name four preparations and dose of each. 10. Atropin: Source, physiologic action and dose.

PHYSIOLOGY AND HISTOLOGY

1. Food: Divided into how many classes, give example and chemical composition of each. 2. Respiration: Describe it, give number in adult and in child one year old. 3. Animal heat: Describe it, give temperature in mouth, axilla and rectum and daily variation. 4. Describe the course and changes nitrogenous, foods undergo in the body. 5. What is the effect of alcohol long continued on the human body? 6. Red corpuscles: Describe them, where formed and destroyed and give function. 7. Describe the general, pulmonary and portal circulation. 8. How is the heart nourished and how is arterial tension maintained? 9. Give histology of skin. 10. Give histology of lobule of human lung.

SPECIAL MEDICINE

1. Define Pott's disease. Make early diagnosis. 2. Define blood pressure. How determined? Give diagnostic value. 3. Give pathology, diagnosis and treatment of progressive muscular atrophy. 4. Name the cardinal symptoms of tumor of the brain. 5. Give etiology, diagnosis and treatment of optic neuritis and optic atrophy. 6. For what conditions and in what strength would you use the following in the eye: boric acid, sulphate zinc, nitrate silver, atropin sulphate, cocaine, bichlorid of mercury and yellow oxid of mercury. 7. Describe, diagnose and treat nasal polyp. 8. Give the etiology, pathology and treatment of the symptom ozena. 9. Diagnose and treat hysterical aphonia. 10. Give etiology, symptoms, diagnosis and treatment of spasm of the larynx in children.

Missouri June Report

Dr. Frank B. Hiller, secretary of the Missouri State Board of Health, reports the written examinations held at St. Louis, and Kansas City, June 13-15, 1910. The number of subjects examined in was 12; total number of questions asked 90, percentage required to pass, 75.

At the examination held at St. Louis, the total number of candidates examined was 125 of whom 114 passed and 11 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Yale Medical School.....	(1909)		87.3
Northwestern University Medical School.....	(1897)		78.6
College of Physicians and Surgeons, Chicago.....	(1910)		82.2

Book Notices

RADIOTHERAPY. By Dr. Louis Wickham, Physician in Saint-Lazare, and Dr. Degrais, Chief of the Laboratory in the Hôpital Saint-Louis. Translated by S. Ernest Dore, M.D., Cantab. With an Introduction by Sir Malcolm Morris, K.C.V.O. Cloth. Price, \$5 net. Pp. 306, with 92 illustrations. New York: Funk and Wagnalls Co., 1910.

This is a personal book, and being at the same time scientific it is all the more interesting and valuable for that fact. It is a temperate effort to state the results of the work which Wickham with the collaboration of Degrais has done in this field. There is first a full consideration of the physics of radium as it bears on its therapeutic use, of its effects on tissues and the reasons therefore, and of the technic of the therapeutic use of the agent. All of this is valuable, but the account of technic is particularly so, as this is in great part the result of Wickham's pioneer work. A large part of the work is devoted to therapeutic results and this is conservative and convincing. The results obtained are for the most part those we have learned to expect from x-rays in epithelioma, leukoplakia, keloid and other scars, and tuberculosis of the skin. The results shown in these conditions are excellent, but they are not superior to those which have been obtained from x-rays in equally competent hands. Indeed, they are striking in their similarity, and support the view that the actinic energy of radium rays and x-rays differ very slightly from each other in their effects on living tissues. A very full description is given of the results in cutaneous angiomas; the subject deserves this, for it is with these lesions that the authors have had their most striking results. The results of the treatment of angiomas with radium are beautiful, surpassing any that have been obtained by any other method of treatment except the still more recent one of refrigeration with liquid air or solid carbon dioxide. Equally good results are shown in pigmented nevi.

The book constitutes a report of original research in therapeutics of the highest interest and of practical value. And the book is worthy of the research; it is scientific in spirit, accurate, without loose or overstatement, and conservative. Even without practical interest in the subject, one should find the book entertaining as showing the marvelous results that are being obtained by scientific workers in these new therapeutic fields.

DUODENAL ULCER. By B. G. A. Mörnhan, M.S., Senior Assistant Surgeon at Leeds General Infirmary, Eng. Cloth. Price, \$4 net. Pp. 367, with 63 illustrations. Philadelphia: W. B. Saunders Co., 1910.

This volume is written in that clear, concise style, which carries the conviction to the reader that the author is master of the subject. There are four short chapters dealing respectively with ulceration of the duodenum in cases of burns or scalds; uremic ulcer; tuberculous ulcer, and ulcer in melenaeonatorum. Then follows a chapter on the important subject, "Symptoms and Diagnosis of Chronic Duodenal Ulcer." The clinical history is so clearly stated that it would seem that the diagnosis should be made almost as easily as the diagnosis of an ordinary case of appendicitis. Some internists perhaps will be somewhat shocked to read: "A description of these symptoms (chronic duodenal ulcer) is to be met with in most of the text-books of medicine under the caption 'hyperchlorhydria' or 'acid gastritis' and the belief that these words are a sufficient diagnosis is very general. After giving a diagnosis of duodenal ulcer I am not infrequently met with the objection that the patient's symptoms are indicative of nothing more than 'persistent hyperchlorhydria.' This is the medical term for the surgical condition duodenal ulcer. Recurrent severe 'hyperchlorhydria' is duodenal ulcer." These are rather strong statements but they are backed up by the unusually large experience of a careful observer who has demonstrated the condition present by operation, therefore must have great weight.

The treatment of duodenal ulcer by gastro-enterostomy and the various accessory operations is well discussed, and the technic of the operations clearly illustrated. The use of the terms "vertical" and "horizontal" to define the direction of the incision or line of suture in the intestine or stomach is confusing and unfortunate, as these words have a very definite meaning when used to indicate direction, which is in no sense

synonymous with "transverse" and "longitudinal." The clinical picture of perforating ulcer is so clearly drawn that it would seem as though failure to recognize these cases in the future should be the exception. In an appendix is found a detailed report of all of the cases operated on by the author up to date.

This is an excellent work and should be carefully studied by every physician who is treating this class of cases, as there are altogether too many patients going the rounds being treated for so-called dyspepsia and indigestion who ought to be relieved permanently by suitable operation.

PRACTICAL RADIUM. By Heber Roberts, M.D., 5899 Cates Ave., St. Louis. Cloth. 1910.

This is one of those books that begin with the author's portrait. And as that would indicate, it is a personal book. The tone of it reminds one of Mr. Dooley's title for Roosevelt's book on the San Juan campaign, "Alone in Cuba." It is filled, not with accepted knowledge of radium and the therapeutic uses of radium, but with the author's peculiar views of this subject. These are curious, often naïve, and by no means lacking in confidence. "Practical Radium. The Causation of Cancer and Its Curability with Radium" (this from the front page). "I have simplified the exposition of cancer . . . so that no error may creep in to divert my meaning. It is therefore within the province of every physician . . . to be able to have at least a well-defined reason for the cause and continuance of cancer, and the methods employed for its relief." "Radium has done more to relieve and eradicate cancer than all other remedies." "Where medicine is employed for the treatment of skin diseases [no qualifications anywhere as to the kind], radium is more effective . . . and requires less time to effect a cure." "In all the varieties of cancer, internal and external, the treatment calls for radium . . ." These sentences selected in five minutes give some idea of the author's restraint. Thirty pages are given to what is called "the exposition of cancer and radium technic." This is in the form of a dialogue and constitutes as gross a piece of balderdash as it is easy to find. It is not instructive; it is not amusing; it is just stupid bombast. In our opinion the book is an offense to the already overtaxed subject of radium therapeutics.

LA GREFFE OVARIENNE: HISTORIQUE; RÉSULTATS CLINIQUES ET THÉRAPEUTIQUES. Par le Docteur Ivan Scheurer. Paper. Price, 4.50 francs. Pp. 152, with 9 illustrations. Paris: G. Steinheil, 2, rue Casimir-Delavigne, 1910.

This monograph of about 180 pages contains a historical review of the experimental work done on animals on the grafting of ovaries, together with the work done by others on the grafting or transplanting of ovaries in the human subject. This part of the subject occupies about 133 pages and is quite complete. Following is a detailed report of the results of the work of Professor Tuffier on the grafting of ovaries in the human subject at the Beaujon Hospital. At the present time Tuffier has had more experience in the grafting of ovaries in women than perhaps any other surgeon and his results demonstrate beyond doubt that the ovary may be successfully grafted. Not only has menstruation become reestablished in women with grafted ovaries but pregnancy has taken place. The ovary has been successfully grafted on the peritoneum near its normal site, on the psoas muscle retroperitoneally, in the cornua of the uterus, in the Fallopian tube, in the subcutaneous tissue of the abdominal wall and in the subperitoneal connective tissue. Success, therefore, does not depend on the location. Tuffier has successfully grafted ovaries that have been kept in cold storage for several days.

The monograph is an interesting one and contains many useful hints regarding the grafting of organs and their subsequent behavior.

DIE RÖNTGENTHERAPIE IN DER DERMATOLOGIE. Dr. Frank Schultz, Privatdozent, Oberarzt der . . . Behandlung und der Kgl. Universitätspoliklini . . . zu Berlin. Paper. Price, 6 marks. Pp. 143, Julius Springer, 1910.

This monograph gives an excellent statement of the present position of Roentgentherapy in dermatology. The author devotes the first 40 pages to a consideration of technic and apparatus. This is a valuable part of the book, because a

satisfactory and not overburdened description of the present day technic and apparatus of *x-ray* therapy is difficult to find. The remaining 100 pages are given to therapeutics, 40 pages to general therapy and the remaining 60 to special therapy. Under special therapy the various dermatoses treated with *x-rays* are considered. The author considers the uses of *x-rays* in various dermatoses from the standpoint of one with large clinical experience, and his views are scientific and temperate. It is interesting to see him confirm again the findings of earlier conservative authors of the value of *x-rays* in dermatology. He gives a convincing summary of the usefulness of *x-rays* in various dermatoses, fortifying his statements with many beautiful reproductions of photographs. These are striking proof of the value of this agent when employed by one who is as well an expert in dermatology as in the use of *x-rays*. It is a valuable addition to the literature of a subject which at present is being undervalued. It well deserves translation and publication in English.

HANDBUCH DER GESAMTEN MEDIZINISCHEN ANWENDUNGEN DER ELEKTRICITÄT einschliesslich der Röntgenlehre. Herausgegeben von Prof. Dr. med. H. Boruttau, Privatdozent für Physiologie an der Universität Berlin, und Prof. Dr. med. L. Mann, Privatdozent für Nervenheilkunde an der Universität Breslau. Band I. Paper. Pp. 599, with illustrations. Leipzig: Dr. Werner Klinkhardt, 1909.

In the first volume of this work, which is to consist of three volumes, is found a very elaborate presentation of the physics and physiochemics of electricity. The various devices, both chemical and mechanical, for the generation of electricity are described in detail as well as all accessory devices such as galvanometers, interrupters, rheostats, commutators, etc. The difference in the physical and chemical properties of the various electric currents such as the direct, alternating, and induced, etc., are explained, following which is an interesting chapter on electro-physiology. A chapter on electropathology or the injurious effects of electricity as seen in lightning stroke or contact with strong industrial currents closes this volume.

The use of electricity is increasing so rapidly and the harmful effects of the strong currents found in the industries are manifested in such a variety of ways that it is necessary for every physician to be familiar with these harmful effects even though he does not make use of electricity as a therapeutic agent. The subject is so important that it would be well if this work were translated so that those who are unable to read it in the original might become familiar with its contents.

Medicolegal

Responsibility for Gauze Left in Kidney Cavity—Obligations of Surgeon—Evidence of Local Custom Excluded— Surgeons Not Liable for Negligence of Hospital Nurses and Interns

The United States Circuit Court of Appeals, Seventh Circuit, says that *Harris vs. Fall* (177 Fed. R. 79), was an action for alleged malpractice brought by the latter party, a resident of Ohio, who authorized his local physician to correspond with the defendant, a Chicago surgeon, with reference to performing an operation, which it was arranged should be performed in a Chicago hospital. The operation was for stone in the right ureter, but none was found, and a subsequent operation was performed wherein the right kidney was removed. The suit arose out of the latter operation and ensuing treatment of the wound, as at some stage of treatment a band of gauze used therein was deposited and left in the kidney cavity, causing serious disturbance until removed long afterwards through another operation.

In reference to the treatment, the defendant testified that he used fabrics to clean out the wound, but left nothing in the wound when finished; that he then packed with drainage, by inserting successively strips of gauze, by means of an instrument, with the strips reaching the bottom of the cavity, the next two inches further up, and so graduating their loca-

tions; that he thus put in five or six strips—making no count or record of the exact number—each strip for such use being seven or eight inches wide and a yard long; that the outer end of each strip was held in a clamp during the process and each remained outside the wound, for removal at the next dressing; that he then sewed up the wound, leaving an opening for packing two to two and one-half inches in length, and then put on the outside dressing.

The patient remained at the hospital some seven weeks after the second operation, under the charge of the defendant, who made frequent examinations of wound and dressings, and on occasions attended to the dressing. Generally, however, one or another of two interns of the hospital attended to the packing and dressing under instructions given them by the defendant.

There was no question but that the defendant was of excellent repute for skill in surgery, and that the removal of the kidney was skillfully performed. But in undertaking this professional work, the obligation was incurred by him to exercise throughout the performance of his engagement both "the ordinary care and skill of his profession, in the light of modern advancement and learning on the subject," and his own best ability, skill, and care. That the facts stated, therefore, established a case of malpractice and serious injury, well within the rule, if the defendant was responsible for the leaving of the gauze in the kidney cavity, was unquestionable.

There was no error in the exclusion of testimony offered by the defendant to show "that at the time and place of the treatment by defendant of plaintiff it was the custom of reasonably careful" surgeons in treating similar cases to leave the "subsequent care of patients in the matter of dressing, packing, and unpacking of such wounds to the house doctor." In each form of tender the proof of custom was thus limited either to Chicago or to the hospital in question—not a general custom. The rule is elementary that such local custom cannot enter into the contract made with a stranger to locality and custom without evidence tending to show notice, and, no offer appearing to prove that either the plaintiff or his Ohio physician, who represented him in the arrangement, was familiar with the alleged local custom, the exclusion of the offered evidence was proper.

The trial resulted in a judgment in favor of the plaintiff for \$4,000 damages, but that is reversed, and a new trial ordered, on account of error in an instruction given the jury that: "The defendant has claimed that even though plaintiff did carry the gauze from Chicago in his body when he left here in March that the defendant is not to be held responsible for that, unless it appears that the defendant was responsible for allowing the plaintiff to go away from here with the gauze in his body as distinguished from the house surgeon, who the testimony shows participated in the treatment and care of the plaintiff during his entire stay at the hospital. But on that question I charge you as a matter of law that the defendant in this case cannot defend himself by saying that what was negligently done to this plaintiff, if negligence there was, is attributable to some one or more of the house surgeons at the hospital. It was his case, and he must discharge his obligation to the plaintiff under the facts in this case as if he had no house physician associated with, or participating with, him in the care and treatment of this plaintiff."

Support for this instruction rested on this proposition: That the engagement of the defendant, under the circumstances in evidence, conclusively implied his obligation, not only to perform and complete the operation—which, as defined in *Akridge vs. Noble*, 114 Ga. 949, "begins when the opening is made into the body and ends when this opening has been closed in a proper way after all appliances necessary to the successful operation have been removed from the body"—but to attend, either personally to all care, dressings and treatment required, or employ professional assistants therefor, until recovery or discharge from such care. The court believes that no such undertaking on the part of the defendant can reasonably be presumed under the evidence, and that it is without sanction under any authority called to attention. The proposition ignored these potent facts: The patient

entered the hospital, contracted there for his room and accommodations, and received care and treatment from its nurses and house physicians throughout his stay, for which he made weekly payments, and the hospital was incorporated for general hospital purposes, under management of a board of trustees, was neither owned nor controlled by the defendant, nor were the house physicians selected or engaged by him, or within his control, except as their services were tendered as a part of the hospital service.

The court believes, moreover, that proof of a local custom in respect of such hospital service was not needful; that the general custom of incorporated general hospitals in like localities, to furnish like service, and of reliance thereon by an independent operating surgeon and by patients therein for the usual care and after-treatment incidental to an operation, are matters within common knowledge and entitled to notice accordingly. In *Baker vs. Wentworth*, 155 Mass. 338, this custom in respect of nurses is recognized, and the operating surgeon held exempt from liability for negligence of the nurses, although the patient supposed (in the absence of representations) that the hospital was owned by the surgeon; and in *Perionowski vs. Freeman*, 4 Foster & F. 977, Chief Justice Cockburn remarked on the practice (there proven) of surgeons leaving care of their patients in various details to the hospital nurses that such practice was "indispensable," and the operating surgeon was not liable for their negligence.

So, these hospital attendants, known as "interns" (usually young physicians), are furnished at the general hospitals to attend to the ordinary work of dressing and treating the wound (left by an operation) on the way to recovery; and the mere undertaking of the surgeon to operate, under call or engagement therefore, cannot, as the court believes, imply his further personal undertaking for the ordinary details of after-treatment, to make the doctrine of respondeat superior (let the superior answer; the principal or master must answer, or is responsible, for the acts of his agent or servant) applicable, to charge him for fault or negligence on the part of such hospital attendants, neither known nor discoverable by the surgeon in the exercise of care and skill throughout his engagement.

No doubt is entertainable, however, that the professional undertaking in this case extended as well to the subsequent visits, observations, and personal treatment in evidence with the attendant obligation for the exercise of skill and care therein.

6. Catching Cold Phobia.—Laying aside unfounded traditions and depending solely on our present knowledge, Brady says that it may be confidently affirmed that the vulgarly listed causes of respiratory disease, such as cold, dampness, exposure, wet feet, and draughts, are, for all practical purposes, entirely negligible factors, and the only precaution necessary against them is the effort to secure bodily comfort, which is purely instinctive, though very commonly misguided. Cold has no demonstrable etiologic relation with respiratory disease. Clean draughts are not only harmless, but salutary, being requisite for perfect ventilation. The phrase "catching cold" is meaningless, misleading, undignified and obsolete. The groundless fear of cold, fostered by the abuse of this misleading phrase, constitutes, he declares, a form of hysteria that opposes and embarrasses earnest therapeutic measures.

So far as we now know, the true predisposing factors of the various respiratory diseases (acute and chronic) are dietetic sins, unhygienic clothing, overheated apartments and defective ventilation. Prophylaxis, therefore, consists in directing intelligently man's instinctive effort to secure bodily comfort, together with reasonable isolation of every case of respiratory disease.

- 12 *Certain Aspects of the Bacteriology of Bacillary Dysentery. A. I. Kendall, Boston.

9. Acute Pancreatitis.—From the literature and the cases which the authors have looked up they conclude that almost all the acute diseases of the pancreas begin as an acute hemorrhagic inflammation, accompanied usually by free fluid in the peritoneal cavity and by disseminated fat necrosis. Operation is the treatment indicated, unless the patient is in such severe collapse that the additional shock would surely be fatal. The object of operation is to drain the pancreatic secretion and the products of infection; this is best done by incising the tissue of the gland, as advised by Porter, and by carrying the drainage through the gastrohepatic omentum close above the lesser curvature of the stomach. They report in detail 16 cases of acute hemorrhagic pancreatitis and 2 cases of suppurative pancreatitis.

10. Surgery of the Vascular System.—Hubbard believes that it may be fairly said that direct transfusion of blood is now a recognized method of treatment in hemorrhage and shock, and in hemorrhagic disease of the new-born; that it is perhaps of benefit in some cases of eclampsia and illuminating gas poisoning, and perhaps in hemophilia, and as a means of improving the condition of a feeble patient to such a point that an operation may be undertaken.

11. Disease of the Maxillary Antrum.—These were cases of what Clark says might very appropriately be called "mucous" disease of the antrum. They were characterized by the presence of a thick, viscid, tenacious mucus in the antrum with an apparently unusually large ostium maxillare. The vasomotor symptoms were prominent.

12. The Bacteriology of Bacillary Dysentery.—Kendall presents briefly certain facts concerning the bacteriology and biochemistry of the dysentery bacillus and associated intestinal flora in bacillary dysentery, with the fundamental principles relating to their activity in the alimentary canal, and mentions the procedures which are theoretically logical for the restoration of a normal intestinal flora. The bacterial flora of the intestinal tract in cases of bacillary dysentery, he says, is putrefactive, chemically speaking, because, as a rule, there is little or no sugar present in the intestinal tract of the body for them to act on. This is equally true for those organisms which succeed in penetrating into the body itself, since the small amounts of dextrose normally present in the blood are usually metabolized early in the disease, particularly under a starvation diet. The remedy for this condition, from the standpoint of bacteriology, is to add an excess of sugar which can be utilized by the bacteria within the intestinal tract and to restore to normal the amount of dextrose in the blood, so that even those organisms which have succeeded in penetrating within the body itself may have an opportunity to act upon sugar rather than on the nitrogen of the tissues of the body.

Dextrose infusions (25 per cent. chemically pure dextrose in normal saline solution) tend to restore this normal dextrose, and also to furnish the body with a considerable amount of fluid. Feeding lactose by mouth (5 per cent. solution) brings about a similar change in the chemistry of the intestinal bacteria.

15. **Pustular Typhoid Roseola.**—On the abdomen and lower anterior portion of the chest of Eggleston's patient there were from 12 to 15, or more, "spots." The majority was small, about 2 or 3 mm. across, rose-red, maculopapular, fading on pressure, and typical typhoid rose spots. Several were somewhat larger and were capped with small vesicles, containing a clear fluid. Two or 3 were very large; each from 10 to 12 mm. in diameter and deep rose-red at the base, which was infiltrated and somewhat elevated, forming a distinct areola about a central yellow pustule. These pustules were tender on direct pressure. They bore no relation to the hair follicles. The vesicles and pustules closely resembled those of variola and varicella. They were, however, somewhat larger and at no time umbilicated. The ninth day of the disease 3 new typical rose spots were observed. A number more appeared on each of the 2 succeeding days. The rose spots, in several instances, became capped with vesicles shortly after their appearance. Some remained vesicular, but a few rapidly went on to form pustules similar to those already described. No new spots appeared after the twelfth day of the disease. The entire eruption was closely confined to the front of the body from the lower chest to the groins. There was no lymphadenitis associated with the pustulation. Those which remained typical rose spots faded in the customary 2 and 3 days after their appearance. The vesicles dried up and were gone in 4 or 5 more days. The pustules disappeared slowly, requiring from 10 to 14 days for resorption. Two of the large ones were opened and the pus expressed. The pus was a very thick, stringy, yellow material, unlike ordinary staphylococcus pus in gross appearance. Smears showed a few leukocytes and pus cells, many threads of mucus, and a few unidentified bacteria. Cultures made from the pus developed a pure growth of the *Staphylococcus aureus*. The patient was noticeably clean and free from any form of skin disease such as acne or parasites. No bathing or hydrotherapy was used in the treatment. The only drug employed was liquor ammonii acetatis. The course of the disease in general was very mild. Only 4 similar cases were found recorded in the literature by Eggleston.

16. **Partial Immobilization of Trunk.**—Williams proposes to immobilize certain parts of the chest for certain periods during the day in the treatment of pulmonary tuberculosis. Although he has used continuous immobilization in some cases for periods of several days, he prefers to run no risks of weakening the sound lung by over-endeavor. He has found it of advantage in many cases, therefore, to apply temporary immobilization, i. e., during certain hours only, these depending on many conditions—stage of the disease, weather conditions, etc. Although he hesitates to lay down rules, he believes that the forenoon is usually the best time for the immobilization. In attempting temporary immobilization of portions of the chest with adhesive plaster there arise at once serious questions of expense in using so many plasters, and the time and trouble spent in their application and removal. To obviate these difficulties he has devised the lacing method. Here the plasters are left in position, being tightened by lacing during certain hours. It is scarcely necessary to state that lacing should be done after a forced expiration, and that enough room should be left between the edges to provide for tight lacing. When any degree of permanency is desired, he prefers strong ticking or canvas. Williams has at present a number of patients under observation, some of whom have been under observation for many months, and though several have been dismissed from active treatment none has been pronounced cured. On some he has applied temporary or permanent half corsets and on others the abdominal binder. He uses hygienic and medical treatment in each case.

47. **Cystocele.**—Gilliam has slightly modified his original operation as follows: (1) an oval denudation of the most prominent part of the cystocele as in the old time operation; (2) dissecting flaps from the vaginal wall on either side of the denuded area with which to cover the latter; (3) bringing the flaps together over the denuded area and suturing them to it and to each other. The result is that the cystocele is effaced, and the site of the cystocele is strengthened by an additional layer of fascia—that taken from the sides of the vaginal wall.

60. Oxygen as an Antiseptic.—The conclusion is drawn by Delcourt that a mixture of oxygen and peroxid of hydrogen is an antiseptic and an antibactericide of first order, superior to those actually used, having no odor and no toxicity. It is specially powerful and specific against infection produced by anaerobic bacteria, and represents our best, and very likely our only, efficacious weapon against gaseous gangrene. It is moreover, a most precious and harmless agent against common suppuration and ordinary infections, irrespective of the offending bacteria. Most of all, those common infections of the skin, be they streptococcus or staphylococcus, vanish as if by magic, before a few peroxid of hydrogen applications.

69. Diagnosis of Pulmonary Tuberculosis.—Three points are emphasized by Garvin in the early diagnosis of the disease. The first is the insidious onset. The second point is the most important physical procedure in the diagnosis, which is auscultated cough. A lung examination which does not necessitate the patient's coughing is not a complete examination, for a case with definite signs will be passed over and marked as negative if this is forgotten. The suspected area can be re-examined again and again during the physical examination in an attempt to develop the suspected signs. Third, the most important working rule for the general practitioner in the fight against this disease is family examination. In 4,500 new cases of pulmonary tuberculosis that applied for treatment at the public clinics in Berlin, under the direction of Dr. Kaiserling, the families of these 4,500 new cases were systematically examined for a discovery of concealed and unknown cases, and as the result of this systematic family examination in these 4,500 cases, 4,500 additional cases of unknown tuberculosis were discovered, many of the patients being in an early and favorable stage for treatment, while many had gone on insidiously and were concealed and unknown bacilli bearers, even to themselves.

70. Alcoholic Psychoses.—Doran endeavors to show that while alcohol is a factor in the production of insanity, it is only one of many, and that even in the forms of insanity commonly considered as due to alcohol, every factor must be given due weight. The exact bearing of alcoholism on the development of insanity is not yet known. He believes, however, that alcohol is more potent in filling poorhouses and penal institutions than asylums, and physicians should do all in their power to educate the people on the possibility of danger in this direction. Certainly they should discourage drinking among those who are hereditarily predisposed, or among the weak-minded and epileptic, because they know that in such cases alcohol is truly a poison and frequently converts such people into dangerous and unsocial lunatics.

79. Immunity in Cancers of White Rat.—Forty rats were treated by Levin for 6 weeks, by hypodermic injections of 1 c.c. of 4 per cent. solution of arsazetin, first every 2 days and then every 4 days. Three weeks after the beginning of the treatment the tumor was inoculated. The arsazetin had no influence on the growth of the tumor, though the quantity of the drug was sufficient to impair considerably the general health of the animals. In nearly every animal a condition was created similar to the state of a waltzing mouse. Another series of animals was treated with autolyzed tissue. The organ for immunization was the liver of "Nul-lers," that is, rats naturally resistant to tumor implantation. The tissue was kept under aseptic precautions at body temperature for two weeks, then the autolyzed tissue was mixed with about double the quantity of normal salt solution, ground thoroughly with sand, filtered, and 1 c.c. of the solution injected subcutaneously. The results compare favorably with those of the investigators who induced immunity with normal tissue. Thus it seems possible to produce in rats a certain amount of resistance to growth of tumor by treatment with tissue of which the cells are killed, but the endocellular ferments apparently remain active. It is interesting to note here that autolyzed liver tissue seems to immunize equally well, whether used before or after the inoculation of the tumor, which fact may be of importance in view of the possibility that the resisting influence of the host may be of two kinds, one to the tumor implantation, the other to tumor growth. Another method consisted in ligating all the vessels of the spleen and from 4 to 12 days after the operation the tumor was inoculated. In another experiment the operation was done 9 days after the inoculation. The results show that the immunizing influence of such a ligated spleen is not so strong as the influence of autolyzed liver injected subcutaneously, and also that this immunizing influence is exerted only on the grafting of the tumor and not on its continued growth. The action of the ligated spleen is probably comparatively weak on account of the rapid absorption of the organ, which prevents the autolysis, and, indeed, no traces of such a spleen were found in the abdominal cavity two days after the operation. A third series of experiments was undertaken which consisted in the subcutaneous inoculation into a rat, of the normal skin and spleen tissue of a mouse, followed in a few days by a subcutaneous inoculation of the tumor. The aim of this treatment was to accustom the tumor cells to mouse tissue and then to observe whether such a rat tumor, which had the opportunity to obtain during its growth the food supplied by the inoculated normal mouse tissue, would not grow more readily when subsequently inoculated into a mouse. The results of this investigation were negative, but the extremely interesting fact was observed that a certain number of the rats treated with mouse tissue appeared immune against growth of the rat sarcoma.

80. Oxidation of Purins by Liver Cells.—Wells' experiments show that it is possible, by proper use of hydrazin and phosphorus, to cause a high degree of fatty change in the liver with a minimum of necrosis, involving alike both peripheral and central portions of the lobule and thus eliminating the

"factor of safety" or residual normal cells. Nevertheless, it is found that such fatty liver tissue has not lost in the least its power to oxidize uric acid when acting on it *in vitro* with abundant air supply, nor is the power to oxidize xanthin to uric acid noticeably diminished. While these experiments merely prove that extreme fatty degeneration does not destroy or appreciably diminish the power of liver cells to oxidize uric acid and xanthin *in vitro*, yet they suggest that in general, fatty degeneration is probably not essentially incompatible with a high degree of metabolic activity by the affected cells. It is possible that in the living tissue functional activity may be decreased secondarily by fatty metamorphosis, as for example, by the enlarged fatty cells compressing the capillaries and reducing circulatory activity, or by modification or diffusion through the cell by the fat deposits, independently of any deleterious influence on the cellular enzymes themselves.

84. Cultivation of Leprosy Bacillus.—The medium on which Duval grew the leprosy bacillus was prepared as follows: The rind was carefully removed from the fruit portion of fully matured green bananas, every precaution to avoid contamination being used, and large blocks of the fruit, after slanting one surface with a sharp knife, were introduced into suitable sterile glass cylinders provided at the bottom with cotton plugs saturated in sterile distilled water. These plugs served not only as support for the banana, but as a source of constant supply of moisture. Sterile 1 per cent. solutions of tryptophan, cystein (made from protein) and leucin were next prepared and a portion of each poured on and allowed to saturate the banana. These solutions were used separately and in varying combinations, in order to determine on which the *B. lepræ* would grow best or grow at all. Both the banana and agar, which was saturated in a 1 per cent. solution of cystein, proved an excellent medium for the artificial cultivation of the leprosy bacilli when incubated at from 32 to 35 degrees C. The maximum growth occurred at a temperature of 32 degrees C. Light seems to favor the growth of *B. lepræ*; cultures kept in a glass incubator regulated at 32 degrees C. grew more rapidly than those in the dark chamber under similar conditions. Multiplication began early in the transplants and visible growth developed in the form of small, glistening, white colonies in from 4 to 6 weeks. Growth also occurred on the banana and agar when a solution of cystein and tryptophan had been added. The fact that growth occurred on the protein-cystein medium, and not on the others except in the presence of it, shows very conclusively that *B. lepræ* utilizes the end-products of digestion and not the products of cell metabolism. At least it is reasonable to assume that this is the case, if deductions may be drawn from these experiments. Multiplication *in vitro* of an acid-fast organism was obtained from the transplanted leprosy tissue on the above mentioned media from four cases of leprosy which corresponded in every essential to the leprosy bacillus. Not only did the leprosy bacilli develop in the original cultures but they continued to grow in subcultures. That the artificial growth is *B. lepræ* there can be no doubt, as the morphologic and cultural features and the animal tests have clearly proved.

95. Extramammary Paget's Disease.—A man, aged 64, was referred to Hartzell on account of a cutaneous affection of the arm, presenting at the time of his first visit the following unusual clinical features: On the outer side of the left forearm, beginning a little above the elbow joint and extending downward, was a palm-sized, circumscribed, irregularly oval patch with a bright red surface, for the most part smooth, but in places slightly scaly, over which were scattered a few pea-sized erosions covered with yellowish crusts, and about the border and within the upper portion a number of flat, shot-sized nodules covered with brownish crusts. In the center of the upper margin of this patch was a rather superficial ulcer about an inch in diameter, with a slightly infiltrated border, covered with exuberant granulations over which were scattered a number of irregularly shaped islands of bluish-white epidermis. The subjective symptoms were trifling, consisting chiefly of moderate itching. The disease had lasted about 15 years, and had until recently, at least, been regarded by the patient and his physician as an eczema and had been treated as such, but with little success. Sections made from the margin of the ulcer presented the histologic features characteristic of a nevo-carcinoma. Sections made from the large patch surrounding the ulcer exhibited some interesting changes, most of them more or less characteristic of Paget's disease. Sections made from the nodule excised showed a sharply circumscribed acanthosis in which the cells were decidedly smaller than normal and had for the most part lost their prickles. The most striking feature of these sections, however, was the narrow, deeply stained band of fibrous tissue and flat cells with elongated and deeply stained nuclei which separated the epithelial mass from the corium beneath, and dipping into it at intervals produced a partial lobulation of it. So far as Hartzell is aware, this is the first reported case in which a nevo-carcinoma has been associated with anything resembling, even remotely, Paget's disease. Moreover, there was apparently a reversal of the usual sequence of events, since the history makes it probable that the carcinomatous degeneration of the nevus preceded the appearance of the Paget's disease.

104. Cancer of the Breast.—The following classification of cases of breast cancer is made by Bryan:

1. Those cases which are seen early, accurately diagnosed by a competent pathologist as cancer. This class offers the best chance of permanent cure by radical surgery—from 50 to 81 per cent.
2. Those cases in which axillary involvement is observed, but without supraclavicular node enlargement. This class gives possibly 25 per cent. cures. Certainly some patients are cured, and the radical operation should be done. Of course, the smaller and fewer the lymph nodes enlarged in the axilla at the time of the operation, the better the chance of cure. The author does not think we are justified by the history of cancer of the breast in condemning all cases with axillary involvement to a hopeless prognosis.
3. Those patients who have ulcerated cancer, and who have infiltration of the pectoral muscles, will perhaps give a very small percentage of cures. This reduces the prognosis much more than enlargement of the axillary nodes does.
4. Those cases in which there is supraclavicular enlargement of the lymph nodes offer very little or no hope of permanent cure, but the limits of life are considerably extended by extirpation.
5. Patients with thoracic and abdominal infiltration (including the spread along lymph channels) and remote (blood) metastases are not curable by surgery, and are to be operated on only for pallia-

tive purposes, such as will add to the comfort of the patient and her attendants or reduce the probability of complications such as infection in the ulcerative cases, or avoid the loss of vitality by hemorrhage or the constant leakage of serum.

107. Inguinal Herniotomy with Special Reference to Cocain Anesthesia.—Dewitt's plea for cocain anesthesia is based on the following points:

1. Many patients are induced to submit to a cure who would not do so with general narcosis, and the anesthesia mortality is removed.
2. The integrity of the nerves is maintained, thus preventing muscle atrophy.
3. There is no vomiting, thus relieving strains on sutures and allowing early administration of food.
4. The danger of ether pneumonia is removed, and there is much less liability to renal insufficiency.
5. Every step in the operation is done with cocain that is carried out with general narcosis.

108. The Diuretic Action of Spartein.—MacNider found that an active preparation of spartein used in a sufficiently large dose produces a rise of general arterial pressure. Following the rise in blood pressure there is an increase in the output of urine, which is likely due to an increase of local blood pressure in the kidney. Following surgical procedures, where the amount of urine is greatly reduced, or where anuria has developed as a result of low general arterial pressure, the amount of urine may be increased and the anuria relieved, through the action of spartein on general blood-pressure, and indirectly on the local kidney-pressure, raising the latter and rendering the kidney functionally more active.

126. Nutmeg Poisoning.—In this case the boy seemed to be suffering from the effects of some narcotic. His pupils were dilated, he staggered in attempting to walk, and on being awakened from sleep would immediately go to sleep again. He complained of a fullness in his stomach, and said that he was drunk. Pulse and respiration were slow, he had no nausea or pain. He said that he had eaten some candy given him by another boy about 4 p. m. He did not recover from the effects until the next morning, when it was discovered that the so-called candy was five or six nutmegs.

147. Remedies.—The practitioner, says Rowe, has not the time, inclination or ability to investigate his drugs thoroughly. This necessitates a reliable source to which he may have access at all times. All drug remedies may be found in one of the following sources: (1) The Pharmacopeia; (2) the National Formulary; (3) the current literature, and (4) New and Nonofficial Remedies. Speaking of the latter Rowe says that proprietary articles not included in New and Non-official remedies are not worthy of a physician's attention. The Council on Pharmacy and Chemistry has shown up fraud and misrepresentation connected with the exploitation of many proprietary articles. It has done more to raise the commercial ethics of pharmaceutical manufacturers than any other agency, not excepting the national Food and Drugs Act. It has given the profession a reliable source of information regarding the value of numerous nonofficial remedies. It has made plainer a scientific drug therapy as contrasted with the haphazard and vicious results of nostrum prescribing.

- 5 *Direct Esophagoscopy. T. J. Faulder.

1. **Treatment of Gastric Ulcer.**—This is a detailed exposition of the treatment of gastric ulcer as employed by internists.

2. **Necessity for Operation in Gastroduodenal Ulceration.**—Monsarrat urges operation in all these cases, even in the absence of any complications.

4. **Cause of Death after Operation for Appendicitis.**—When suffering from an ordinary attack of appendicitis there are, according to Brown, three lines of defense by which the organism protects itself. The first line is the lymph agglutination of mesentery, intestines, etc., around the appendix, which limits the abscess, and prevents infection of the general peritoneal cavity with pus. It is these adhesions which surgeons are so careful to preserve, and fearful of breaking down. The second line of defense is a more important one. This is a layer of lymph covering the surface of the intestine and omentum and forming the wall of the abscess cavity. Brown believes that this lymph acts as a filter, allowing soluble toxins to pass through into the lymphatics and blood stream of the surrounding viscera, but presenting a barrier to the passage of bacilli, like the porcelain of a Berkefeld filter. It is this barrier which it is all important to preserve until

the third line of defense has been established. The third line is in the blood itself; the passage of toxins into the circulation results in a rise of temperature, quickening of pulse, etc., and the formation of protective antibodies in the serum. More and more toxin passes through as time goes on, and the abscess becomes larger, until, in course of time, generally during the second week of an attack, the temperature may fall to normal, or nearly so, and the serum become saturated with antibodies.

By this time the patient has become protected. If the abscess is opened, foul-smelling pus flows freely over the abdominal wound, which may afterward be sutured for the greater part of its extent and heal by first intention, without even any sign of redness around the stitches. There is no more danger to the patient than in opening an abscess anywhere else. The moral, Brown says, is obviously this: 1. Do not be in a hurry to operate, unless an operation can be performed within the first 24 hours, when the mischief is presumably confined to the appendix itself, or when general peritoneal infection is impending or has already taken place. 2. When definite abscess has formed, wait until after the first week; when about ten days have elapsed it is probable that protection will be complete. During this period the patient should, of course, be kept under close observation, so that an operation can take place at any time, if necessary. 3. Be contented to drain the cavity. Gentle flushing may be employed at the time of the operation if preferred, but do not do more than is necessary for this purpose. 4. Above all things, if operating early, simply evacuate the pus without touching the abscess wall, and leave the appendix to be dealt with at a later date when all infection has sub-sided.

5. Direct Esophagoscopy.—These 8 examinations recorded by Faulder were made on patients varying from 30 to 70 years of age, 4 males, 3 females. Two of them took place under general anesthesia; in the others no anesthetic was used, or only a little cocaine brushed over the pharynx. He is convinced that these examinations show that esophagoscopy is safe and practical. As regards anesthesia, a sensible patient can be of great assistance to the surgeon if he be conscious. He can swallow when directed to do so, he can alter the position of head or neck as required, and his sensations are to some extent a safeguard against damage. For these reasons a beginner should not use general anesthesia, although it spares the patient much discomfort and permits of a longer and more careful examination than would otherwise be the case.

16. Snake Venom.—It is with the hemolysins of Australian venoms that the authors have mostly worked, and they give a descriptive account of their action, and note their bearing on the general question of immunity. These venoms include

those of the black snake (*Pseudechis porphyriacus*), the fierce snake (*Pseudechis ferox*), the brown snake (*Dicmenia texilis*), the tiger snake (*Notechis scutatus* s. *Hoplocephalus curtus*), the death adder (*Acanthophis antarcticus*), the broad-headed snake (*Hoplocephalus bungaroides* s. *variegatus*), and, among monotremes, the poison gland of *Lichidna aculeata*. Among the red blood cells tested with one or more of these venoms were those of man, the dog, horse, pig, sheep, ox, and snake. The experiments were designed to test the interaction of varying quantities of venom with (1) red blood cells washed free of serum, (2) red cells and fresh serum, and (3) red cells and serum heated to (a) from 56 to 60 C., (b) 85 c., and (c) 100 C.

The following general results were obtained:

1. As in the case of Indian and American species, the venoms of different Australian snakes vary greatly in their hemolytic effects; and, by testing with the washed corpuscles of some relatively susceptible species, it is possible to grade the venoms according to their toxicity for the hemocytes.

2. The washed corpuscles of different species of mammals differ greatly in their susceptibility and resistance to individual venoms, and may be grouped accordingly. Corpuscles which are most sensitive to one venom are found to be most sensitive to others also; and corpuscles which are most resistant to one venom are most resistant to others.

3. The presence of the fresh homologous serum, in minute or moderate quantity, has not, in their experience, activated any venom for corpuscles that are insensitive when washed. With susceptible corpuscles in the fresh serum has in some instances reinforced the action of venom—that is, serum complement or serum lecithin has been superadded to the endolecithin. With other susceptible corpuscles, however, the fresh serum has inhibited the hemolytic action of the venom—that is, inhibitory substances in the serum have predominated.

4. Heating the serum does not produce much change for or against activation at the lower temperature, 56 to 60 C., indicating that serum complements are not much concerned in the interaction. But, at higher temperatures, 85 C. and notably at 100 C., a marked effect is noted. When the venom can dissolve the washed corpuscles, the addition of serum heated to 100 C. accelerates and extends the hemolysis; and, in some instances where the washed corpuscles are not affected by venom, the presence of serum similarly heated so activates the venom as to induce hemolysis probably by liberation of lecithin.

5. In some combinations of venom corpuscles and heated homologous serum, no hemolysis occurs, and yet, with the same venom, the same corpuscles and a heated heterologous serum marked hemolysis may take place, indicating that heating different sera renders available very different amounts of a venom activator, probably lecithin.

17. Symptom-Complex in Ruptured Abdominal Hydatid.—

The facts presented by Barling and Welsh have reference to a series of 6 cases of hydatid disease complicated by rupture or leakage of the cyst into the peritoneal cavity. In 5 of the cases the cyst was situated in the liver, in the remaining case in the spleen. In 50 per cent. of the cases examined the blood change was a marked one, in another 25 per cent. the change was moderate, while in the remaining 25 per cent. it was entirely absent or so slight that it was of no use from a diagnostic point of view. The authors found eosinophilia to be a marked feature of every case in which the cyst had ruptured or leaked into the abdominal cavity. The actual number of the eosinophils present in the blood in the 6 cases varied considerably. In 3 the reaction was excessive, the actual figures being in the first case 8,580 eosinophils per c.mm., or a number equal to 54 per cent. of the leukocyte content of the blood; in the second case there were 8,200 eosinophils per c.mm., or a number equal to 47 per cent. of the leukocytes; in the third case there were 5,440 eosinophils per c.mm., or a number equal to 34 per cent. of the total leukocytes. In two of the remaining cases the blood change was a marked one, there being in one of them 1,628 eosinophils per c.mm., a number equal to 22 per cent. of the total leukocytes, and in the other 1,320 eosinophils per c.mm., a number equal to 12 per cent. of the leukocytes present. In the one remaining case the reaction, though slight, was definite, there being 354 eosinophils per c.mm., a number equal to 5.6 per cent. of the total leukocytes.

The second outstanding feature of these cases of ruptured abdominal hydatid is the peritonitis set up by the presence of the hydatid material in the peritoneal sac. The most noticeable feature of this peritonitis is the large amount of fluid which is poured forth. The third feature is the urticaria which attends the rupture of the hydatid cyst. In the cases which have come under the author's notice it was invariably present.

In 2 of the 6 patients no history of a rash could be obtained, although careful inquiries were made on this point. In

high responsible positions and brain workers. They presented various degrees of obesity, flatulence or aerophagy but all had in common a tendency to dizziness, oppression in the heart region, palpitations, scotoma, enlargement of the veins, especially in the neck, and a gray or yellowish complexion sometimes suggesting cachexia. A little shortness of breath after muscular exertion was the only complaint in regard to dyspnea. In this condition, as the patient breathes the thorax is seen to be less movable than normal. The maximal blood pressure is high, averaging from 125 mm. mercury for the minimum to 170 or 180 mm. maximum (Gaertner's tonometer), but the pressure returns to normal when normal conditions in the respiration are restored. Sometimes in the cases reported the blood-pressure differed in the right and left sides. Treatment should aim to promote diaphragmatic respiration by training the costal muscles to perform their task, exercising them to increase their tonicity, while regulating the diet to strengthen the muscles. In conclusion the author warns that the atony of the stomach and intestines in the corpulent with considerable meteorism may simulate a higher degree of obesity than actually exists. In treating obesity the aim should be, he says, not so much to reduce the weight as to render the patient's muscles more functionally capable. The greater demands on the muscular capacity, however, require a corresponding amount of albumin in the food; the diets which neglect this fail to supply conditions favorable for correction of the atony of the stomach.

65. Importance of Direct Visual Inspection in Rectal Disease.—Pewsnar has applied recto-sigmoidoscopy in 73 cases in the last 5 years and has found it valuable in detection of inflammation and cancer in the incipient phases. In some cases the only complaint was severe constipation, in others merely tenesmus. Even ulceration in the lower segment of the bowel may occur without symptoms to attract attention to the lesion. He was able by this early direct visual inspection to discover cancer in 3 cases, 13, 16 and over 18 cm. above the anus which had escaped digital examination. The only symptoms had been occasional false impulses for defecation. The technic of direct visual inspection is simple and easy, far more so than cystoscopy, he says, and he urges internists to adopt it as a routine measure.

67. Tuberculosis of the Esophagus.—Burekhardt reviews the cases on record of this perhaps rarest of all localizations of tuberculosis, and then describes a personal case in a man of 60; the lesion is evidently secondary to advanced processes in the lungs. In a second personal case there was no chronic lung affection and no tuberculous sputum to be swallowed but there were tuberculous meningitis and tuberculous lesions in the fibula, etc.

Centralblatt für die Grenzgebiete der Med. und Chir., Jena
August 13, XIII, No. 14, pp. 529-560

68 *Thrombosis and Embolism of the Mesenteric Vessels. D. G. Zesas. Commenced in No. 9.

68. Thrombosis and Embolism of the Mesenteric Vessels.—Zesas found 363 articles in the literature bearing on this subject, all of which he reviews. The results to date of operative treatment are not very encouraging—only 5 cases of recovery out of 13 in which the infarcted part of the bowel involved was resected. Only 7 cases are known of simultaneous obliteration of both vein and artery. Massage is particularly dangerous if mesenteric thrombosis or embolism is suspected. Exploratory laparotomy is indispensable. In 13 cases conditions were found inoperable but Tschudy cured a patient by packing with gauze to shut off the infarcted region, keeping the abdominal wound open. Symptoms of ileus had come on 3 days after an interval appendicectomy; the entire cecum was transformed into a bluish solid tumor but there was no gangrene, and the permeability of the bowel was restored in a few hours. Mouchet has reported a similar case but the patient succumbed. The details of 6 other cases are related in which an artificial anus was made but none of the patients survived the embolism. Kölbing has reported a case in which gastroenterostomy was done after resection of the infarcted loop, with recovery of the patient, a woman of 31 who had had diarrhea for several days with increasing

abdominal pain and vomiting and tympanitic resonance over a loop of intestine on the left side. In 13 other cases the loop of intestine involved was resected, with recovery of 5 of the patients. Thrombosis of a mesenteric vessel has been observed in a month-old babe and in 2 children of 5 and 8, but the majority of patients were between 30 and 60.

69. Ehrlich's "606" in Syphilis.—Herxheimer states that in 11 weeks' experience with "606" and 83 cases of syphilis no by-effects of consequence were noticed beyond the local painfulness and febrile reaction, all of which are avoided by the later improved technic. There was transient retention of urine in one neurasthenic patient, but urination became normal again at once after a sitz bath. The reflexes behaved normally in all cases. According to Ehrlich's directions, the fundus of the eye, the heart, lungs, liver and kidneys were investigated in every case before the drug was given and any pathologic findings caused the patient to be excluded from this method of treatment. The findings in regard to spirochetes, the blood count and the Wassermann reaction were also recorded. No spirochetes could be discovered in 82 cases 48 hours after the injection, nor has recurrence been observed during the 11 weeks to date. In the other case the spirochetes did not seem to be affected by the drug, and A. Glück has encountered 2 similar cases; it seems as if certain rare strains of spirochetes must be insusceptible to the action of the drug, just as some have been known to be mercury-fast. In a case of universal psoriasis of 18 years' standing there was extensive desquamation after the injection but after 48 hours conditions had returned apparently to the same as before the injection. Otherwise, Herxheimer's experience has been favorable in regard to the efficacy of the drug and, like others, he mentions especially its prompt and effectual action in malignant syphilis. [Jellinek raises a warning voice not to be too hasty in judgment of the new remedy for syphilis, saying that the lay press throughout Germany is proclaiming it far and near as a prompt and radical cure for syphilis and is thus throwing down the barriers against venereal infection by removing the fear of syphilis. Jellinek comments further on the actual criminal optimism which is being fostered among the masses by the marvelous stories in regard to "606" that are issuing from the hospitals. He says this in the *Klin.-therap. Wochenschrift*, 1910, XVII, 80, in commending a pamphlet on sexual hygiene by Prof. S. Ribbing of Lund, Sweden, which he regards as a model work for young men on this subject.]

74. Painless Operations on the Bones of the Face and the Mouth Under Local Anesthesia.—Offerhaus' method of obtaining access to the trigeminal nerve for relief of neuralgia by injection of alcohol was described in *THE JOURNAL*, August 13, 1910, page 630. He here states that the method is proving valuable for local anesthesia for operations on the face, jaws and mouth in which the cooperation of the patient is of inestimable advantage. By the technic described it is possible, he says, to locate the foramen desired without the least trouble and without previous trials on the cadaver, except under very unusual conditions. He has applied this technic for injection of a local anesthetic in 11 cases and the results were good in 9, the failure in the others being due to the displacement of the nerve by the cancerous growth for which the operation was undertaken. He usually gives a sedative to the patients before injecting the anesthetic, and

he does not attempt to apply this technic for local anesthesia in case the patient is very nervous and excitable. In the cases adapted for it, however, the advantages are great. The illustrations explain the technic described. He has applied the technic for treatment of severe trigeminal neuralgia in 12 more cases since those reported in his previous communi-

from a dry rubber sponge inside a girdle is useful in the cases in which pressure relieves the pain.

79. Constitutional Factor in Nervous Disturbances.—Margulies writes from the clinic in charge of von Jaksch at Prague to relate a number of cases of recurring oculomotor paralysis or toxic polyneuritis in which the evidence seems to sustain the assumption that certain nerves or nervous systems are congenitally predisposed to yield more readily to injurious influences than those in other persons. This assumption is confirmed by the occurrence of certain affections in families. Some parts of the nervous system, especially the peripheral, are peculiarly non-resistant in these persons and yield readily to injurious external influences, while other regions and other individuals escape. In conclusion, he re-

ports a case of toxic polyneuritis in a father and 2 sons, the symptoms suggesting cholera and being followed by pains and paralysis in the legs, all coming on simultaneously in the 3 men after eating heartily of a dish of rice. The father succumbed by the end of the second week, with all the extremities paralyzed. The young men have recovered some ability to walk during the year since, but suffer from pains in the legs and early exhaustion. The syndrome suggested beriberi, especially as it came on immediately after eating rice. There had been no disturbances elsewhere in the town from eating the rice from the same bag, and nothing abnormal could be discovered about the rice when examined by the author. Everything speaks for the assumption, he is convinced, of a constitutional susceptibility on the part of the nervous system involved; the clinician should strive to distinguish this

constitutional factor in the syndrome observed from the symptoms peculiar to the affection in question.

81. Ehrlich's "606" in Syphilis.—Braendle and Clingstein report their experiences with 27 cases of syphilis. The results were sometimes brilliant but in others not particularly satisfactory, fully as good results being attainable, they say, under the ordinary measures. The promptly favorable action of the drug in malignant syphilis, however, was particularly striking. By-effects were observed in the vascular system; in several patients the blood-pressure was increased immediately after the injection while from the second to the third day the pulse was inclined to be accelerated and small but there were no threatening symptoms. Three patients, however, presented signs of collapse of brief duration. (Spatz has reported similar experiences in the *Wiener med. Wochenschrift*, 1910, No. 27.) The pulse kept fast longer than corresponded to the fever. Other symptoms eventually ascribable to arsenic intoxication were headache, dizziness, nausea and vomiting which were observed in several cases. Only slight by-effects on the part of the nervous system were noted; in about a fourth of the cases the tendon reflexes were exaggerated for a few days after the injections. Most of the patients gained greatly in weight after the injection, a gain of from 6 to 15 pounds in a few weeks being the rule. The Wassermann reaction has persisted positive to date in all

cation; in 10 of the cases a complete cure was realized and material improvement in another case while in still another case the trouble was of central origin and naturally no benefit was derived. Except for a few weeks of stiffness and pain in chewing in one case, no untoward by-effects were observed.

76. Stretching the Nerve in Treatment of Sciatica and Other Nervous Disease.—Heermann pulls on the leg of the reclining patient, exerting about as much force as for pulling off a boot. If this relieves the pain of the sciatica, he applies extension systematically, raising the extended leg once or twice a day to the point borne without special pain and then applying extension to the foot with the leg resting on an inclined plane. This is repeated cautiously once or twice a day for from 5 to 30 seconds at a time. This stretching is supplemented by stretching the leg backward for a few seconds as the patient lies on the side. The ordinary measures are also applied but the nerve stretching often proves successful alone. For adjuvant massage he places his hands flat and gently on the abdomen and sacrum of the patient as he lies on his side. If the patient shrinks, he stops at once, but if the pressure is gratefully received he massages with the flat hand, making circular motions and gradually approaching nearer and nearer to the points of greatest pain. This massage in combination with the extension relieved the pain better than sedatives in some of his cases. Pressure

positive and 23 with negative findings, the latter group including 5 cancer cases.

- 118 *Successful Puncture of Intestine or Enterotomy in Six Cases of Ileus. (Sex fall af ileus, med framgång behandlade med tarmpunktion resp. enterotomi, jämte några ord om den därvid användda operationstekniken.) E. A. Eriksson.
119 *Gumma at the Cardia. (Till den visceral syfilis' kasuistik. Gumma cardia.) C. Cronquist.
120 Case of Rupture of Brain Tissue. (Ett fall af hjärnbräck.) H. Malmqvist.
121 Successful Cesarean Section in Patient with Contracted Pelvis and Heart Defect. (Kejsarsnitt med lycklig utgång vid trängt bäcken och hjärtfel.) A. Troell.
122 Rupture of Bladder During Alcohol Intoxication. (Ett fall af blåsruptur i samband med alkoholförbrukning.) T. Frieberg.
123 Case of Acardius Amorphus. C. F. Hefjell.

118. Puncture of Intestine or Enterotomy for Ileus.—The ileus was due to volvulus of the cecum and colon or sigmoid flexure, paralysis of the bowel after herniotomy, coprostasis and adhesions or diverticulitis in Eriksson's 6 cases. Treatment in each was by a laparotomy and puncture of the bowel; in only a few of the cases was it necessary to make an actual enterotomy, the lesser operation generally sufficing. Since Eriksson has restricted his ileus operations to mere puncture the outcome has been generally good; he has lost only one patient, a man of 64 with ileocecal invagination and bronchitis, who succumbed to chloroform intoxication.

119. Gumma in the Cardia.—Cronquist's patient was a man of 42 who had had some difficulty in swallowing for three years, gradually growing more and more severe. The presumptive diagnosis was cancer of the cardia, but a casual remark led to the discovery of a history of certain symptoms years before suggesting possible syphilis. Under tentative mercurial treatment the stenosis at the cardia rapidly subsided.

- 124 *How Long Should the Lying-In Woman Stay in Bed? (Hvorlænge bør en barselkvinde ligge tilsengs?) K. Brandt and J. Horn.
125 *Infected Cystic Kidney. Recovery After Nephrectomy. (Inficeret cystenyre; nefrektomi; helbredelse.) P. Bull.
126 Functional Tests of the Heart. (Den funktionelle diagnostik, dens maal og midler, specielt med hensyn till hjertets funktion.) S. Madsen.

124. How Long Should Women Stay in Bed After Delivery?—Brandt and Horn state that their investigation of the subject has shown that involution and healing are not well under way before the tenth or twelfth day. If the woman gets up before this date infection is liable to occur and may easily be overlooked while a predisposition to genital prolapse may develop.

125. Infected Cystic Kidney.—Bull remarks that the diagnosis is generally very difficult, as the physician seldom thinks of the possibility of this rare condition. The cystic kidney is peculiarly liable to become infected. Sieber found infection mentioned in 10 per cent. of 200 cases on record, and Borelius in 1 of his 4 cases. Bull calls attention to the family tendency in his cases; a man and 3 of his 11 children and a brother and sister had cystic kidneys, the diagnosis being confirmed by operation or autopsy. The symptoms came on about the age of 24, and none of the third generation has reached this age yet. Notwithstanding that the tendency to cystic kidney is bilateral as a rule, if one kidney is predominantly affected while its mate is still functionally capable, nephrectomy may be indicated. He reviews the northland literature on the subject and Sieber's monograph. In only 9 of the 200 cases was only 1 kidney involved, as determined at autopsy; both were involved in 150. In about 12 per cent. of all the cases the lesion had never induced appreciable symptoms. The urine may be normal but generally is like that with contracted kidney. The kidney region is usually tender and there may be vague or sharp pains, constant or

paroxysmal. Intermittent hematuria was observed in 20 per cent. of the cases, hypertrophy of the heart in 50 per cent. and a hemorrhagic tendency was frequently apparent, apoplexy even in the young, epistaxis, intestinal hemorrhage and hemoptysis. Nephrectomy was done in 61 cases with 20 fatalities; 8 of the patients are still living after from 3 to 7 years. Nephrotomy was done in 10 cases, on both kidneys in 4, with 2 fatalities.

- 127 *The Leukocyte Count in Different Parts of the Circulation at the Same Time. (Om Leukocyttælling og Inhomogenitet.) V. Ellermann and A. Erlandsen.
August 18, No. 33, pp. 969-996

128 Indications for Treatment in Appendicitis. E. Müller.

127. The Leukocyte Count and Inhomogeneity.—This latter term has been coined by Kjer-Petersen to express a variability in the leukocyte count in blood taken from different points in the circulation at about the same time. He found wide variations in this respect, but Ellermann and Erlandsen were unable to discover any tendency of the kind in 110 double examinations of the blood of 64 women patients.

Books Received

Books received are acknowledged in this column and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

A LABORATORY TEXT-BOOK OF EMBRYOLOGY. By Charles S. Minot, LL.D. (Yale and Toronto). James Stillman, Professor of Comparative Anatomy in the Harvard Medical School. Second Edition. Cloth. Price, \$3.50 net. Pp. 402, with 262 illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

THE EFFECTS OF A RESTRICTED DIET AND OF VARIOUS DIETS ON THE RESISTANCE OF ANIMALS TO CERTAIN POISONS. By Reid Hunt. Paper. Pp. 93. Bull. 69, Hyg. Lab., P. H. and M.-H. S. Washington: Government Printing Office, 1910.

VACCINE THERAPY. Its Theory and Practice. By R. W. Allen, M.D., Late Clinical Pathologist to the Mount Vernon Hospital for Diseases of the Chest. Third Edition. Cloth. Price, \$2 net. Pp. 277. P. Blakiston's Son & Co., 1910.

New Patents

Recent patents of interest to physicians:

956258. Window tent. John G. Allen, Peoria, Ill.
955937. Atomizer. John R. Ballentine, Toledo, Ohio.
955938. Atomizer. John R. Ballentine, Toledo, Ohio.
956052. Pocket-atomizer. Frank C. Dormont, Detroit, Mich.
956325. Massage cup or tip. Joseph B. Fey, Columbus, Ohio.
956120. Producing manganates, permanganates, halogens and hydroxids. Florentine J. Machalske, Chicago.
956155. Invalid's chair. Rosa M. Olmsted, Columbus, Ind.
956438. Crutch tip. Edward H. Seibert, St. Louis.
956221. Magnetic tachometer. John K. Stewart, Chicago.
957035. Pasteurizer. Hans Christensen, Fort Atkinson, Wis.
956734. Manufacturing methane or mixtures of methane and hydrogen. Paul Sabatier, Toulouse, France.
957295. Recovering potash salts. Augusto Alberti, Rome, Italy.
957548. Inhaler. Walter S. Doane, Worcester, Mass.
957758. Swing for osteopathic tables. William E. Fogle, Bath, N. Y.
957761. Making sodium sulfite and ammonium chlorid. Richard Friedrich, Glosa, near Chemnitz, Germany, and F. Hirsh, Vienna, A. H.
957204. Making a medicinal compound. Anton Garlesan, Chicago.
957718. Device for the correction of flat foot, weak foot or fallen arch of the foot. Frederick C. Schumacher, New York.
957267. Prophylactic drinking vessel. James L. Sowell, Jasper, Ala.
957449. Disinfectant holder. Charles J. Walz, New Haven, Conn.
958697. Atomizer. Frank C. Dormont, Detroit.
958488. X-ray tube. Henry Green, Hartford, Conn.
958133. Sterilizer and drier. Aage Jensen, Eureka, Cal.
958259. Disinfecting device. Fernand Le Faguays, Nantes, France.
957976. Atomizer and the like. Owen D. Lucas, Bayswater, London, England.
958267. Truss. Thomas E. Martin, Buffalo, N. Y.
957982. Electric vibrator. Sampson W. Moon, Chicago.
958527. Respirator (smoke protector). Martin Panlan, Eveleth, Minn.
958536. Spraying attachment. Charles H. Rath, Philadelphia.
958179. Surgical instrument. John S. Rydell, Minneapolis.
958180. Producing tantalum. Johannes Schilling, Halesnec, near Berlin, Germany.
958569. Respirator and inhaler. Richard Venner, Barre, Vt.
958199. Corn and bunion plaster. Eugene J. Ward, New York.
407221. sign prescription case. Charles F. Kurz, Cleveland, O.
